In the second quarter of the 18th century (1729) Stephen Gray in a series of interesting experiments for the first time demonstrated the difference between conductors and non-conductors (insulators) showing amongst other things that a metal wire and even pack thread conducted electricity, whereas silk did not. In one of his experiments he sent an electric current through 700 feet of hempen thread which was suspended at intervals by loops of sil thread. Subsequently Du Fay transmitted a current through a wet hempen string to a distance of 1,256 feet, the string being insulated by means of glass. In 1741 Mr. Ellicott «proposed to measure the strength of electrification by its power to raise a weight in one scale of a balance while the other was held over the electrified body and pulled to it by its attractive power» (Carpue).

The Sir William Watson already mentioned, conducted numerous experiments about 1749, to ascertain the velocity of electricity in a wire, which experiments although perhaps not so intended, also demonstrated the possibility of transmitting signals to a distance by electricity. In these experiments an insulated wire 12,276 feet in length was employed and the transmission of a signal from one end of the wire to the other appeared to the observers to be instantaneous. Monnier (q.v.) in France had previously made somewhat similar experiments, sending shocks through an iron wire 1,319 feet long.

About 1737 Hawkesbee and Du Fay independently discovered that there were apparently two kinds of frictional electricity, namely that which is developed by rubbing glass and resin, respectively. The former electricity Du Fay termed "vitreous," the latter "resinous" electricity. Later, these electricities were termed "positive" and "negative" electricity, respectively, by Franklin, Dr. Watson, Lichtenberg and others.

Theories regarding the nature of electricity were quite vague at this period, and those prevalent were more or less conflicting. Franklin considered that electricity was an imponderable fluid pervading everything, and which, in its normal condition, was uniformly distributed in all substances. He assumed that the electrical manifestations obtained by rubbing glass were due to the production of an excess of the electric fluid in that substance and that the manifestations produced by rubbing wax were due to a deficit of the fluid. This theory was opposed by the "two-fluid" theory due to Robert Symmer, 1759. By Symmer's theory the vitreous and resinous electricities were regarded as imponderable fluids, each fluid being composed of mutually repellent particles while the particles of the opposite electricities are mutually attractive. When the two fluids unite by reason of their attraction for one another, their effect upon external objects is neutralized. The act of rubbing a body decomposes the fluids one of which remains in excess on the body and manifests itself as vitreous or resinous electricity.

About 1750 various tests were made by different experimenters to ascertain the physiological and therapeutical effects of electricity. Mainbray (or Mowbray) in Edinburgh examined the effects of electricity upon plants and concluded that the growth of two myrtle trees was quickened by electrification. These myrtles were electrified "during the whole month of October, 1746, and they put forth branches and blossoms sooner than other shrubs of the same kind not electrified." (Priestley's 'History of Electricity,' p. 138.) The Abbé Menon tried the effects of a continued application of electricity upon men and birds and found that the subjects experimented on lost weight, thus apparently showing that electricity quickened the excretions. The efficacy of electric shocks in cases of paralysis was tested in the county hospital at Shrewsbury, England, with rather poor success. ('Philosophical Transactions,' p. 786, 1754.) In one case reported a palsied arm was somewhat improved, but the dread of the shocks became so great that the patient preferred to forego a possible cure rather than undergo further treatment. In another case of partial paralysis the electric treatment was followed by temporary total paralysis. A second application of this treatment was again followed by total paralysis, whereupon the further use of electricity in this case was stopped. For further accounts of the early use of electricity as a remedial agent the reader may consult De la Rive's 'Electricity.' See also article ELECTRO-THERAPEUTICS.

Up to the time of Franklin's historic kite experiment (see ELECTRICITY, ATMOSPHERIC) the identity of the electricity developed by rubbing and by electric machines (frictional electricity), with lightning had not been generally established. Dr. Wall, 1807, Abbot Nollet, Hawkesbee, Gray and Winckler had indeed suggested the resemblance between the phenomena of "electricity" and "lightning," Gray having intimated that they only differed in degree. It was doubtless Franklin, however, who first proposed tests to determine the sameness of the phenomena. In a letter to Peter Conlinson, London, 19 Oct. 1752, Franklin, referring to his kite experiment, wrote, "At this key the phial (Leyden jar) may be charged; and from the electric fire thus obtained spirits may be kindled, and all the other electric experiments be formed which are usually done by the help of a rubbed glass globe or tube, and thereby the sameness of the electric matter with that of lightning be completely demonstrated." (Franklin, 'Experiments and Observations on Electricity.') Dalibard, at Marley, near Paris, on 10 May 1772 by means of a vertical iron rod 40 feet long, obtained results corresponding to those recorded by Franklin and somewhat prior to the date of Franklin's experiment.

Franklin's important demonstration of the sameness of frictional electricity and lightning doubtless added zest to the efforts of the many experimenters in this field in the last half of the 18th century, to advance the progress of the science. Amongst those workers may be mentioned Watson, Boze, Smeaton, Le Monnier, De Romas, Jallabert, Beccaria, Cavallo, John Canton, Robert Symmer, Nollet, Winckler, Richman, Dr. Wilson, Kinnersley, Priestley, Aepinus, Delaval, Cavendish, Coulomb, Volta and Galvani. A description of many of the experiments and discoveries of these early workers in the fields of electrical science and art will be found in the scientific publications of the time; notably the 'Philosophical Transactions,' *Philosophical Magazine, Cambridge Mathematical Journal,* Young's 'Natural Philosophy,' Priestley's 'History of Electricity,' 'Franklin's Experiments and Observations on Electricity,' Cavalli's 'Treatise on Electricity,' De la Rive's 'Treatise on Electricity.' Among the more important of the electrical experiments and researches at this period were those of Francis Aepinus, a noted German scholar (1724-1802) and Henry Cavendish of London, England. To Aepinus is accorded the credit of having been the first to conceive the view of the reciprocal relationship of electricity and magnetism. In his work 'Tentamen Theoria Electricitatis et Magnetismi,' published in Saint Petersburg, 1759, he gives the following amplification of Franklin's theory, which in some of its features is measurably in accord with present day views: "*The particles of the electric fluid repel each other and attract and are attracted by the particles of all bodies with a force that decreases in proportion as the distance increases; the electric fluid exists in the pores of bodies; it moves unobstructedly through non-electrics* (insulators), *but moves with difficulty in insulators; the manifestations of electricity are due to the unequal distribution of the fluid in a body, or to the approach of bodies unequally charged* *with the fluid.*" Aepinus formulated a corresponding theory of magnetism excepting that in the case of magnetic phenomena the fluids only acted on the particles of iron. He also made numerous electrical experiments, amongst others those apparently showing that in order to manifest electrical effects tourmalin requires to be heated to a temperature between 37.5°C and 100°C. In fact, tourmalin remains unelectrified when its temperature is uniform, but manifests electrical properties when its temperature is rising or falling. Crystals which manifest electrical properties in this way are termed pyro-electrics, amongst which, besides tourmalin are sulphate of quinine and quartz.

Cavendish independently conceived a theory of electricity nearly akin to that of Aepinus ('Philosophical Transactions,' 1771). He also (1784) was perhaps the first to utilize the electric spark to produce the explosion of hydrogen and oxygen in the proper proportions to produce pure water. The same philosopher also discovered the inductive capacity of dielectrics (insulators) and as early as 1775 measured the specific inductive capacity of beeswax and other substances by comparison with an air condenser. Unfortunately much of the work of Cavendish was not for many years available to his contemporaries and successors, although on record.

About 1784 C. A. Coulomb, after whom is named the electrical unit of quantity, devised the torsion balance, by means of which he discovered what is known as Coulomb's law;—*The force exerted between two small electrified bodies varies inversely as the square of the distance;* not as Aepinus in his theory of electricity had assumed, merely inversely as the distance. According to the theory advanced by Cavendish "the particles attract and are attracted inversely as some less power of the distance than the cube."

With the discovery, by the experiments of Watson and others, that electricity could be transmitted to a distance, the idea of making practical use of this phenomenon began, about 1753, to engross the minds of "inquisitive" persons, and to this end suggestions looking to the employment of electricity in the transmission of intelligence were made. The first of the methods devised for this purpose was probably that due to Lesage (1774). This method consisted in the employment of 24 wires, insulated from one another and each of which had a pith ball connected to its distant end. Each wire represented a letter of the alphabet. To send a message, a desired wire was charged momentarily with electricity from an electric machine, whereupon the pith ball connected to that wire would fly out; and in this way messages were transmitted. Other methods of telegraphing in which frictional electricity was employed were also tried, some of which are described in the article on the Telegraph (q.v.).

Hitherto the only electricity known was that developed by friction or rubbing, which was therefore termed frictional electricity. We now come to the era of galvanic or voltaic electricity. The first mention of voltaic electricity, although not recognized as such at the time, was probably made by Sulzer in 1767, who on placing a small disk of zinc under his tongue and a small disk of copper over it, observed a peculiar taste when the respective metals touched at their edges. Sulzer assumed that when the metals came together they were set into vibration, this acting upon the nerves of the tongue, producing the effects noticed.

In 1790 Professor Luigi Alvisio Galvani of Bologna on one occasion, while conducting experiments on "animal electricity," as he termed it, to which his attention had been turned by the twitching of a frog's legs in the presence of an electric machine, observed that the muscles of a frog which was suspended on an iron balustrade by a copper hook that passed through its dorsal column, underwent lively convulsions without any extraneous cause; the electric machine being at this time absent. To account for this phenomenon Galvani assumed that electricity of opposite kinds existed in the nerves and muscles of the frog; the muscles and nerves constituting the charged coatings of a Leyden jar.

Galvani published the results of his discoveries, together with his hypothesis, which at once engrossed the attention of the physicists of that time; the most prominent of whom, Alexander Volta, Professor of Physics at Pavia, contended that the results observed by Galvani were due to the two metals, copper and iron, acting as "electromotors," and that the muscles of the frog played the part of a conductor, completing the circuit.

This precipitated a long discussion between the adherents of the conflicting views; one set of adherents holding with Volta that the electric current was the result of an electromotive force of contact at the two metals; the other set adopting a modification of Galvani's view and asserting that the current was due to a chemical affinity between the metals and the acids in the pile. Michael Faraday wrote in the preface to his 'Experimental Researches,' relative to the question whether metallic contact is or is not productive of a part of the electricity of the voltaic pile: "I see no reason as yet to alter the opinion I have given; . . . but the point itself is of such great importance that I intend at the first opportunity renewing the inquiry, and, if I can, rendering the proofs either on the one side or the other, undeniable to all." Even Faraday himself, however, did not settle the controversy, and while the views of the advocates on both sides of the question have undergone modifications, as subsequent investigations and discoveries demanded, up to the present day diversity of opinion on these points continues to crop out.

Volta made numerous experiments in support of his theory and ultimately developed the pile or battery (see VOLTAIC PILE), which was the precursor of all subsequent chemical batteries, and possessed the distinguishing merit of being the first means by which a prolonged continuous current of electricity was obtainable.

Volta communicated a description of his pile to the Royal Society of London and shortly thereafter Nicholson and Cavendish (1880) produced the decomposition of water by means of the electric current, using Volta's pile as the source of electromotive force. Davy in 1806, employing a voltaic pile of approximately 250 cells, or couples, decomposed potash and soda, showing that these substances were respectively the oxides of potassium and sodium, which metals previously had been unknown. These experiments were the beginning of electro-chemistry (q.v.) the investigation of which Faraday took up, and concerning which in 1833 he announced his important law of electro-chemical equivalents, viz.: "*The same quantity of electricity—that is, the same electric current—decomposes chemically equivalent quantities of all the bodies which it traverses; hence the weights of elements separated in these electrolytes are to each other as their chemical equivalents.*" Employing a battery of 2,000 elements of a voltaic pile Humphry Davy in 1840 gave the first public demonstration of the electric arc light (q.v.) using for the purpose charcoal enclosed in a vacuum.

Somewhat singular to note, it was not until many years after the discovery of the voltaic pile that the sameness of animal and frictional electricity with voltaic electricity was clearly recognized and demonstrated. Thus as late as January, 1833, we find Faraday writing ('Philosophical Transactions,' 1833) in a paper on the electricity of the torpedo. "After an examination of the experiments of Walsh, Ingenhousz, Cavendish, Sir H. Davy, and Dr. Davy, no doubt remains on my mind as to the identity of the electricity of the torpedo with common (frictional) and voltaic electricity; and I presume that so little will remain on the mind of others as to justify my refraining from entering at length into the philosophical proof of that identity. The doubts raised by Sir H. Davy have been removed by his brother, Dr. Davy; the results of the latter being the reverse of those of the former. . . . The general conclusion which must, I think, be drawn from this collection of facts (a table showing the similarity of properties of the diversely named electricities) is, that electricity, whatever may be its source, is identical in its nature."

It is proper to state, however, that prior to Faraday's time the similarity of electricity derived from different sources was more than suspected. Thus, William Hyde Woolaston (another noted and careful experimenter in electricity and the discoverer of palladium and rhodium, b. 1766; d. 1828), wrote in 1801 (*Philosophical Magazine*, Vol. III, p. 211): "This familiarity in the means by which both electricity and galvanism (voltaic electricity) appear to be excited in addition to the resemblance that has been traced between their effects shows that they are both essentially the same and confirm an opinion that has already been advanced by others, that all the differences discoverable in the effects of the latter may be owing to its being less intense, but produced in much larger quantity." In the same paper Woolaston describes certain experiments in which he uses very fine wire in a solution of sulphate of copper through whch he passed electric currents from an electric machine. This is interesting in connection with the later day use of almost similarly arranged fine wires in electrolytic receivers in wireless, or radiotelegraphy.

In the first half of the 19th century many very important additions were made to the world's knowledge concerning electricity and magnetism. For example, in 1819 Hans Christian Oersted of Copenhagen discovered the deflecting effect of an electric current traversing a wire upon a suspended magnetic needle. This discovery gave a clue to the subsequently proved intimate relationship between electricity and magnetism which was promptly followed up by Ampère who shortly thereafter (1821) announced his celebrated theory of electrodynamics, relating to the force that one current exerts upon another, by its electro-magnetic effects, namely: (1) "*Two parallel portions of a circuit attract one another if the currents in them are flowing in the same direction, and repel one another if the currents flow in the opposite direction.* (2) *Two portions of circuits crossing one another obliquely attract one another if both the currents flow either towards or from the point of crossing, and repel one another if one flows to and the other from that point.* (3) *When an element of a circuit exerts a force on another element of a circuit, that force always tends to urge the latter in a direction at right angles to its own direction.*"

Professor Seeback, of Berlin, in 1821 discovered that when heat is applied to the junction of two metals that had been soldered together an electric current is set up. This is termed Thermo Electricity. (See THERMO-ELECTRICITY.) Seeback's device consists of a strip of copper bent at each end and soldered to a plate of bismuth. A magnetic needle is placed parallel with the copper strip. When the heat of a lamp is applied to the junction of the copper and bismuth an electric current is set up which deflects the needle.

Peltier in 1834 discovered an effect opposite to the foregoing, namely that when a current is passed through a couple of dissimilar metals the temperature is lowered or raised at the junction of the metals, depending on the direction of the current. This is termed the Peltier "effect." The variations of temperature are found to be proportional to the strength of the current and not to the square of the strength of the current as in the case of heat due to the ordinary resistance of a conductor. This latter is the C^2R law, discovered experimentally in 1841 by the noted English physicist, Joule. In other words, this important law is that the heat generated in any part of an electric circuit is directly proportional to the product of the resistance of this part of the circuit and to the square of the strength of current flowing in the circuit.

In 1822 Sweigger devised the first galvanometer (q.v.). This instrument was subsequently much improved upon by Wilhelm Weber (1833). In 1825 William Sturgeon of Woolwich, Eng., invented the horse-shoe and straight bar electromagnet, and in recognition therefor received the silver medal of the Society of Arts ('Trans. Society of Arts,' 1825). In 1837 Gauss and Weber (both noted workers of this period) jointly invented a reflecting galvanometer for telegraph purposes. This was the forerunner of the Thomson reflecting and other exceedingly sensitive galvanometers once used in submarine signaling and still widely employed in electrical measurements. Arago in 1824 made the important discovery that when a copper disk is rotated in its own plane, and if a magnetic needle be freely suspended on a pivot over the disk, the needle will rotate with the disk. If on the other hand the needle be fixed it will tend to retard the motion of the disk. This effect was termed Arago's rotations. Futile attempts were made by Babbidge, Barlow, Herschel and others to explain this phenomenon. The true explanation was reserved for Faraday, namely, that electric currents are induced in the copper disk by the cutting of the magnetic lines of force of the needle, which currents in turn react on the needle. In 1827 George Simon Ohm (q.v.) announced the now famous law that bears his name, that is:

$$\text{Current} = \frac{\text{Electromotive force}}{\text{Resistance.}}$$

In 1831 began the epoch making researches of Michael Faraday (q.v.), the famous pupil and successor of Humphrey Davy (q.v.) at the head of the Royal Institution, London, relating to electric and electro-magnetic induction.

Faraday's studies and researches extended from 1831 to 1855 and a detailed description of his experiments, deductions and speculations are to be found in his compiled papers, entitled, 'Experimental Researches in Electricity.' Faraday was by profession a chemist. He was not in the remotest degree a mathematician in the ordinary sense—indeed it is a question if in all his writings there is a single mathematical formula. His writings are conspicuous for the simplicity, modesty and clearness of his language. An example of this may be given, taken from the closing words of a paper on 'Thoughts on Ray Vibrations': "I think it likely," he says, "that I have made many mistakes in the preceding pages, for even to myself my ideas on this point appear only as the shadow of a speculation, or as one of those impressions on the mind, which are allowable for a time as guides to thought and reasearch. He who labors in experimental enquiries knows how numerous these are, and how often their apparent fitness and beauty vanish before the progress and development of real natural truth."

The experiment which led Faraday to the discovery of electric induction was made as follows. He constructed what is now and was then termed an induction coil, the primary and secondary wires of which were wound on a wooden bobbin, side by side, and insulated from one another. In the circuit of the primary wire he placed a battery of approximately one hundred cells. In the secondary wire he inserted a galvanometer. On making his first test he observed no results, the galvanometer remaining quiescent, but on increasing the length of the wires he noticed a deflection of the galvanometer in the secondary wire when the circuit of the primary wire was made and broken. This was the first observed instance of the development of electromotive force by electromagnetic induction. He also observed the now well known facts that induced currents are established in a second closed circuit when the current strength is varied in the first wire, and that the direction of the current in the secondary circuit is opposite to that in the first circuit. He also discovered that a current is induced in a secondary circuit when another circuit carrying a current is moved to and from the first circuit. Also that the approach or withdrawal of a magnet to or from a closed circuit induces momentary currents in the latter. In short, within the space of a few months Faraday discovered by experiment virtually all the laws and facts now known concerning electro-magnetic induction and magneto-electric induction. Upon these discoveries with scarcely an exception, depends the operation of the telephone, the dynamo machine, and incidental to the dynamo electric machine (q.v.) practically all the gigantic electrical industries of the world, including electric lighting (q.v.) electric traction (q.v.), the operation of electric motors for power purposes, and electro-plating (q.v.), electrotyping (q.v.), etc.

In his investigations of the peculiar manner in which iron filings arrange themselves on a cardboard or glass in proximity to the poles of a magnet, Faraday conceived the idea of magnetic "lines of force" extending from pole to pole of the magnet and along which the filings tend to place themselves. On the discovery being made that magnetic effects accompany the passage of an electric current in a wire, it was also assumed that similar magnetic lines of force whirled around the wire. For convenience and to account for induced electricity it was then assumed that when these lines of force are "cut" by a wire in passing across them, or when the lines of force in "rising" and "falling" "cut" the wire, a current of electricity is developed, or to be more accurate, an electromotive force is developed in the wire that sets up a current in a closed circuit.

Faraday also advanced what has been termed the molecular theory of electricity which assumes that electricity is the manifestation of a peculiar condition of the molecules of the body rubbed, or the ether surrounding the body. Faraday also, by experiment, discovered paramagnetism and diamagnetism, namely that all solids and liquids are either attracted or repelled by a magnet. For example, iron, nickel, cobalt, manganese, chromium, etc., are paramagnetic (attracted by magnetism), whilst other substances, such as bismuth, phosphorus, antimony, zinc, etc., are repelled by magnetism, or are diamagnetic ('Phil. Trans.' 1845). Brugans of Leyden in 1778 and Le Baillif and Becquerel 1827 had previously discovered diamagnetism, in the case of bismuth and antimony. Faraday also rediscovered specific inductive capacity in 1837, the results of the experiments by Cavendish not having been published at that time. He also predicted (*Phil. Mag.*, March, 1854) the retardation of signals on long submarine cables due to the inductive effect of the insulation of the cable, in other words, the static capacity of the cable.

The twenty-five years immediately following Faraday's discoveries of electric induction were fruitful in the promulgation of laws and facts relating to induced currents and to magnetism. In 1834 Lenz and Jacobi independently demonstrated the now familiar fact that the currents induced in a coil are proportional to the number of turns in the coil. Lenz also announced at that time the important law that, *in all cases of electromagnetic induction the induced currents have such a direction that their reaction tends to stop the motion that produces them*, a law that was perhaps deducible from Faraday's explanation of Arago's rotations.

In 1845 Joseph Henry, the American physicist, published an account of his valuable and interesting experiments with induced currents of a high order, showing that currents could be induced from the secondary of an induction coil to the primary of a second coil, thence to its secondary wire, and so on to the primary of a third coil, etc. (*Philosophical Magazine* 1840). Abria published the results of some researches into the laws of these induced currents, but owing to their complexity the investigation was not productive of very notable results. ('Ann. de Chimie III,' i, 385.) About 1850 Kirchoff published his laws relating to branched or divided circuits. He also showed mathematically that according to the then prevailing electrodynamic theory, electricity would be propagated along a perfectly conducting wire with the velocity of light. Helmholtz investigated mathematically the effects of induction upon the strength of a current and deduced therefrom equations, which experiment confirmed, showing amongst other important points, the retarding effect of self-induction under certain conditions of the circuit ('Poggendorf Ann.' 1851). In 1853 Sir William Thomson (now Lord Kelvin) (q.v.) predicted as a result of mathematical calculations the oscillatory nature of the electric discharge of a condenser circuit. To Henry, however, belongs the credit of discerning as a result of his experiments in 1842 the oscillatory nature of the Leyden jar discharge. He wrote ('Proc. Am. Phil. Soc.' Vol. II, pp. 193, 196): *The phenomena requires us to admit the existence of a principal discharge in one direction, and then several reflex actions backward and forward, each more feeble than the preceding, until the equilibrium is obtained.* These oscillations were subsequently observed by Feddersen (1857) who using a rotating concave mirror projected an image of the electric spark upon a sensitive plate thereby obtaining a photograph of the spark which plainly indicated the alternating nature of the discharge. Sir William Thomson was also the discoverer of the electric convection of heat (the 'Thomson" effect). He designed for electrical measurements of precision his quadrant and absolute electrometers. The reflecting galvanometer and siphon recorder as applied to submarine cable signaling, are also due to him, and in general the names Thomson-Kelvin, stand out prominently amongst the foremost practical and theoretical electric engineers as well as scientists and philosophers of two generations. Of him Mr. John Perry has written: "While it is useless to speculate on what might have occurred had Sir William Thomson condescended to write in 1857 a text-book on electricity such as he was then capable of producing, it may safely be said that it is very seldom that a man's inability to comprehend how ignorant his contemporaries are, has produced such evil effects in retarding the progress of industrial invention." ('Electricity in the Service of Man,' p. 22.)

About 1876 Professor H. A. Rowland of Baltimore demonstrated the important fact that a static charge carried around, produces the same magnetic effects as an electric current. The importance of this discovery consists in that it may afford a plausible theory of magnetism, namely that magnetism may be the result of directed motion of rows of molecules carrying static charges.

After Faraday's discovery that electric currents could be developed in a wire by causing it to cut across the lines of force of a magnet, it was to be expected that attempts would be made to construct machines to avail of this fact in the development of voltaic currents (See DYNAMO-ELECTRIC MACHINERY and ELECTRIC DIRECT CURRENT). The first machine of this kind was due to Pixii, 1832. It consisted of two bobbins of iron wire, opposite which the poles of a horseshoe magnet were caused to rotate. As this produced in the coils of the wire an alternating current, Pixii arranged a commutating device (commutator) that converted the alternating current of the coils or armature into a direct current in the external circuit. This machine was followed by improved forms of magneto-electric machines due to Ritchie, Saxton, Clarke, Stohrer, 1843, Nollet, 1849, Shepperd, 1856, Van Maldern, Siemens, Wilde, and others.

A notable advance in the art of dynamo construction was made by Mr. S. A. Varley in 1866 (see his British patent of that year) and by Dr. Charles William Siemens and Mr. Charles Wheatsone (see 'Royal Society Proceedings,' 1867) who independently discovered that when a coil of wire, or armature, of the dynamo machine is rotated between the poles (or in the "field") of an electromagnet, a weak current is set up in the coil due to residual magnetism in the iron of the electromagnet, and that if the circuit of the armature be connected with the circuit of the electromagnet, the weak current developed in the armature increases the magnetism in the field. This further increases the magnetic lines of force in which the armature rotates, which still further increases the current in the electromagnet, thereby producing a corresponding increase in the field magnetism, and so on, until the maximum electromotive force which the machine is capable of developing is reached. By means of this principle the dynamo machine develops its own magnetic field, thereby much increasing its efficiency and economical operation. Not by any means, however, was the dynamo electric machine perfected at the time mentioned. In 1860 an important improvement had been made by Dr. Antonio Pacinotti of Pisa who devised the first electric machine with a ring armature. This machine was first used as an electric motor, but afterwards as a generator of electricity. The discovery of the principle of the reversibility of the dynamo electric machine (variously attributed to Walenn, 1860; Pacinotti, 1864; Fontaine, Gramme, 1873; Deprez, 1881; and others) whereby it may be used as an electric motor or as a generator of electricity has been termed one of the greatest discoveries of the 19th century. In 1872 the drum armature was devised by Helfner-Altneck. This machine in a modified form was subsequently known as the Siemens dynamo. These machines were presently followed by the Schuckert, Gulsher, Fein, Brush, Hochhausen, Edison and the dynamo machines of numerous other inventors.

In the early days of dynamo machine construction the machines were mainly arranged as direct current generators, and perhaps the most important application of such machines at that time was in electro-plating, for which purpose machines of low voltage and large current strength were employed. (See ELECTRIC DIRECT CURRENTS.) Beginning about 1887 alternating current generators came into extensive operation and the commercial development of the static transformer, by means of which currents of high voltage and low current strength are transformed to currents of low voltage and large current strength, in time revolutionized the transmission of electric power to long distances. Likewise the introduction of the rotary converter (in connection with the "step-down" transformer) which converts alternating currents into direct currents (and vice versa) has effected large economies in the operation of electric power systems. (See ELECTRIC ALTERNATING CURRENT MACHINERY.)

Before the introduction of dynamo electric machines, voltaic, or primary, batteries were extensively used for electroplating, and in telegraphy. There are two distinct types of voltaic cells, namely the "open," and the "closed," or "constant," type. The open type in brief is that type which operated on closed circuit becomes, after a short time, polarized; that is, gases are liberated in the cell which settle on the negative plate and establish a counter electromotive force that opposes the normal electromotive force of the cell. After a brief interval of open circuit these gases are eliminated or absorbed and the cell is again ready for operation. Closed circuit cells are those in which the gases in the cell are absorbed as quickly as liberated and hence the output of the cell is practically uniform. The Leclanché and Daniell cells, respectively, are familiar examples of the "open" and "closed" type of voltaic cell. The "open" cells are used very extensively at present, especially in the dry cell form, in telephony, and in annunciator and other open circuit signal systems. Batteries of the Daniell or "gravity" type were employed almost generally in the United States and Canada as the source of electromotive force in telegraphy before the dynamo machine became available. Batteries of the "gravity" and the Edison-Lalande types are still much used in "closed circuit" systems.

The possibility of obtaining the electric current in large quantities, and economically, by means of dynamo electric machines gave impetus and incentive to the development of incandescent and arc lighting. Before these machines had reached a commercial basis voltaic batteries were the only available source of current for electric lighting and power. The cost of these batteries, however, and the difficulties of maintaining them in reliable operation were at that time prohibitory of the use of the electric current for practical lighting purposes. The date of the employment of arc and incandescent lamps may be set at about 1877. Even in 1880, however, but little headway had been made towards the general use of these illuminants; the rapid subsequent growth of this industry is a matter of general knowledge. (See ELECTRIC LIGHTING.) The employment of storage batteries (q.v.), which were originally termed secondary batteries or accumulators, began about 1879. Such batteries are now utilized on a large scale as auxiliaries to the dynamo machine in electric power houses and sub-stations, in electric automobiles, in fire alarm telegraphy and other signal systems.

In 1871 the electric telegraph had grown to large proportions and was in use in every civilized country in the world, its lines forming a network in every direction over the surface of the land. The system most generally in use was, then as now, the electromagnetic telegraph due to S. F. B. Morse of New York, or modifications of his system. (See TELEGRAPH.) Submarine Cables (see CABLES) connecting the Eastern and Western hemispheres were also in successful operation at that time. When, however, at the present day (1907) one views the many and great applications of electricity to electric light, electric railways, electric power and other purposes (all it may be repeated made possible and practicable by the perfection of the dynamo machine) it is difficult to believe that no longer ago than 1871 the author of a book published in that year, in referring to the state of the art of applied electricity at that time could have truthfully written: "The most important and remarkable of the uses which have been made of electricity consists in its application to telegraph purposes" (Miller's 'Magnetism and Electricity,' p. 460). The statement was, however, quite accurate and perhaps the time could have been carried forward to the year 1876 without material modification of the remarks. In that year the telephone (q.v.), due to Alexander Graham Bell (q.v.), was invented, but it was not until several years thereafter that its commercial employment began in earnest. Since that time also the sister branches of electricity just mentioned have advanced and are advancing with such gigantic strides in every direction that it is difficult to place a limit upon their progress. For a more adequate account of the use of electricity in the arts and industries see ELECTRIC MANUFACTORY INDUSTRIES.

Perhaps without exception the greatest advance in the world's knowledge of electricity past or present was made when James Clark Maxwell of Edinburgh—the "heaven sent" Maxwell, as his contemporaries have spoken of him—announced that "undying masterpiece," the electromagnetic theory of light. (Consult Maxwell's 'Electricity and Magnetism,' Vol. XI., Chap. xxii.)

As already noted herein Faraday, and before him, Ampère and others, had inklings that the luminiferous ether of space was also the medium for electric action. It was known by experiment and calculation that the velocity of electricity was approximately 186,000 miles per second, that is, equal to the velocity of light, which in itself suggests the idea of a relationship between electricity and "light." A number of the earlier philosophers or mathematicians, as Maxwell terms them, of the 19th century held the view that electromagnetic phenomena were explainable by action at a distance. Maxwell, following Faraday, contended that the seat of the phenomena was in the medium. The methods of the mathematicians in arriving at their results were synthetical while Faraday's methods were analytical. Faraday in his mind's eye saw lines of force traversing all space where the mathematicians saw centres of force attracting at a distance. Faraday sought the seat of the phenomena in real actions going on in the medium; they were satisfied that they had found it in a power of action at a distance on the electric fluids. (Maxwell's 'Electricity and Magnetism,' preface.)

Both of these methods, as Maxwell points out, had succeeded in explaining the propagation of light as an electromagnetic phenomenon while at the same time the fundamental conceptions of what the quantities concerned are radically different. The mathematicians assumed that insulators were barriers to electric currents; that for instance, in a Leyden jar or electric condenser the electricity was accumulated at one plate and that by some occult action at a distance electricity of an opposite kind was attracted to the other plate. Maxwell looking further than Faraday, reasoned that if light is an electromagnetic phenomenon and is transmissible through dielectrics such as glass, the phenomenon must be in the nature of electromagnetic currents in the dielectrics. He therefore contended that in the charging of a condenser, for instance, the action did not stop at the insulator, but that "displacement" currents are set up in the insulating medium which currents continue until the resisting force of the medium equals that of the charging force. In a closed circuit conductor an electric current is also a displacement of electricity. The conductor offers a certain resistance akin to friction to the displacement and heat is developed in the conductor, proportional as already stated herein to the square of the current, which current flows as long as the impelling electric force continues. This resistance may be likened to that met with by a ship as in its progress it displaces the water. The resistance of the dielectric is of a different nature and has been compared to the compression of multitudes of springs, which, under pressure yield with an increasing back pressure, up to a point where the total back pressure equals the initial pressure. When the initial pressure is withdrawn the energy expended in compressing the "springs" is returned to the circuit, concurrently with the return of the springs to their original condition, this producing a reaction in the opposite direction. Consequently the current due to the displacement of electricity in a conductor may be continuous, while the displacement currents in a dielectric are momentary and, in a circuit or medium which contains but little resistance compared with capacity or inductance reaction, the currents of discharge are of an oscillatory or alternating nature (See OSCILLATORY CURRENTS; WIRELESS TELEGRAPHY). Maxwell expanded this view of displacement currents in dielectrics to the ether of free space. Assuming light to be the manifestation of alternations of electric currents in the ether, and vibrating at the rate of light vibrations, these vibrations by induction set up corresponding vibrations in adjoining portions of the ether, and in this way the undulations corresponding to those of light are propagated as an electromagnetic effect in the ether. Maxwell's electromagnet theory of light, first announced in 1865, obviously involved the existence of electric waves in free space, and his followers set themselves the task of experimentally demonstrating the truth of the theory. This honor was reserved for Prof. H. Hertz who in 1887 in a series of masterly experiments proved the actual existence of such waves. The discovery of electric waves in space naturally led to the discovery and introduction of that marvel of the closing years of the 19th century, wireless telegraphy (1894) various systems of which are now in successful use on shipboard and lighthouses throughout the world, notably those of Marconi, Slaby-Arco and De Forest. (See WIRELESS TELEGRAPHY.)

In 1801 notable additions to our knowledge of the phenomena of high frequency and high potential currents were contributed by Nikola Tesla (q.v.). (Consult 'Proc. Ann. Inst. El. Engrs.' 1001). Amongst the novel experiments performed by Tesla was to take in his hand a glass tube from which the air had been exhausted, then bringing his body into contact with a wire carrying currents of high potential, the tube was suffused with a pleasing bright glow. Another experiment was to grasp a bulb that was suspended from a single wire attached to a high potential, high frequency current circuit, when a platinum button within the bulb was brought to vivid incandescence, the experimenter at this time standing on an insulating platform. The frequency and potential of many of the experiments made by Tesla at this time were of the order of one or more million cycles and volts. For further information relative to these experiments the reader may be referred to Tesla's 'Experiments with Alternate Currents of High Potential and High Frequency.' This book also contains an outline description of Tesla's proposed method of transmitting electric energy without wires.

The place of electricity in leading up to the discovery of those beautiful phenomena of the Crooks Tube (due to Sir William Crooks), viz. Cathode rays (consult 'Proc. British Association,' 1879), and later to the discovery of X-rays, must not be overlooked, since without electricity as the excitant of the tube the discovery of the rays might have been postponed indefinitely. Radium and some of its emanations have been detected without the aid of electricity, but the most sensitive device available to determine the radio-activity of this and other radio-active elements is electrical, namely, the electroscope.

It has been noted herein that Dr. William Gilbert was termed the founder of electrical science. This must, however, be regarded as a comparative statement. Up to the middle of the 19th century, indeed up to about 1870, electrical science was, it may be said, a sealed book to the majority of electrical workers. Prior to this time a number of hand-books had been published on electricity and magnetism, notably Aug. de La Rive's exhaustive 'Treatise on Electricity,' 1851 and (in the French) 1835, Beer's 'Einleitung in die Electrostatik,' Wiedemann's 'Galvanismus,' and Reiss' 'Reibungsal-elektricitat.' But these works consisted in the main in details of experiments with electricity and magnetism, and but little with the laws and facts of those phenomena. About this time Fleeming Jenkin's work on 'Electricity and Magnetism' and Clark-Maxwell's 'Treatise on Electricity and Magnetism' were published. These books were departures from the beaten path. As Jenkin states in the preface to his work the science of the schools was so dissimilar from that of the practical electrician that it was quite impossible to give students any sufficient, or even approximately sufficient, text-book. A student he said might have mastered De la Rive's large and valuable treatise and yet feel as if in an unknown country and listening to an unknown tongue in the company of practical men. As another writer has said, with the coming of Jenkin's and Maxwell's books all impediments in the way of electrical students were removed, "the full meaning of Ohm's law becomes clear: electromotive force, difference of potential, resistance, current, capacity, lines of force, magnetization and chemical affinity were measurable, and could be reasoned about, and calculations could be made about them with as much certainty as calculations in dynamics" (Introduction to 'Electricity in the Service of

Man'). Since that time also the real science of electricity has rapidly advanced. Various units of electricity and magnetism have been adopted and named by representatives of the electrical engineering institutes of the world, which units and names have been confirmed and legalized by the governments of the United States and other countries. Thus the Volt, from the Italian Volta, has been adopted as the practical unit of *electromotive force*, the Ohm (from the annunciator of Ohm's law) as the practical unit of *resistance;* the Ampère (after the eminent French scientist of that name) as the practical unit of *current strength*, the Henry as the practical unit of *inductance*, after Joseph Henry, and in recognition of his early and important experimental work in mutual induction. See UNITS; ELECTRICAL TERMS.

The theories regarding electricity are also undergoing change. Indeed it may with truth be said that the trend of all scientific investigation now leads to the conclusion that matter in its final analysis is electrical in its nature—in fact is electricity; the theory upon which this view is based being termed the electronic theory, or the electric theory of matter. (See ELECTRON.)

This theory (or better, hypothesis) in a word assumes that the atom of matter, so far from being indivisible, as assumed under the older theories, is made up of smaller bodies termed electrons or corpuscles, that these electrons are electrical in their nature, and consequently all matter ultimately is electrical. This theory of matter though of comparatively recent origin in several of its important features is not altogether one of a day, nor is it due to the researches of one man or to the conception of one mind. Thus, as regards the view that the atom is not an indivisible particle of matter, but is made up of numerous electrons, many scientists have for years held that all the elements are modifications of a single hypothetical substance, protyle, "the undifferentiated material of the universe." Nor is the theory entirely new in its assumption that all matter is electrical. Faraday, Weber, Helmholtz, Clifford, and others had glimpses of this view; and the experimental work of Zeeman, Goldstein, Crooks, J. J. Thomson, and others had greatly strengthened this view. Over 35 years ago Weber predicted that electrical phenomena were due to the existence of electrical atoms, the influence of which on one another depended on their position and relative accelerations and velocities. Helmholtz and others also contended that the existence of electrical atoms followed from Faraday's laws of *electrolysis*, and Johnstone Stoney, to whom is due the term "electron," showed that each chemical ion of the decomposed electrolyte carries a definite and constant quantity of electricity, and inasmuch as these charged ions are separated on the electrodes as neutral substances there must be an instant, however brief, when the charges must be capable of existing separately as electrical atoms; while in 1887, Clifford (q.v.) wrote: "There is great reason to believe that every material atom carries upon it a small electric current, if it does not wholly consist of this current."

Whether the electronic theory will survive or itself will in turn be displaced by some more suitable theory remains for the future to determine. In the meantime, be that as it may, the practical application of electricity will go on apace. It is an every day saying of laymen that electricity is as yet in its infancy. This remark causes technical men to smile, for "electricity" is already a most prodigious infant. But in the sense that we may only be on the threshold of the possible utilizations of this most wonderful of nature's agents, the remark is perhaps true. Predictions that were with diffidence made but twenty years ago to the effect that within 100 years of that time people would probably speak to one another without artificial means of communication; that wires would be laid along every street and tapped into every house as gas pipes were then, for lighting and power purposes, have for a decade been facts accomplished. What the next twenty years shall bring forth with regard to the applications of electricity none can tell. Ten years ago it would have been difficult to find one steam railroad engineer willing to admit that application of electric traction to steam railroads was a possibility. To-day the entering wedge in this direction has been made for the improvement of railroad terminal facilities, and it is now difficult to find one steam railroad engineer who will deny that in twenty years hence all the important steam railroads of this country may not be operated electrically. In other directions the progress of events as to the utilization of electric power may be expected to be equally rapid. In every part of the world the power of falling water, nature's perpetual motion machine, which has been going to waste since the world began, is now being converted into electricity and transmitted by wire hundreds of miles to points where it is usefully and economically employed. It is already in contemplation to convey the power of the falling waters of Victoria Nyanza on the Zambezi in the heart of Africa, to points five and six hundred miles remote. But the extensive utilization of falling water will not be limited to natural water falls. In hundreds of places where a fall of 40 to 400 feet extends over 10 to 50 miles, and where in the aggregate hundreds of thousands of horse power, by suitable hydraulic methods are available, this power (already termed "white coal" in some parts of Europe) will be usefully employed, thereby in large measure conserving the limited quantity of the world's coal. It is, for instance, already proposed to dam Niagara river at the foot of the gorge whereby another source of water power equal to that at the present falls would be available. The Jehlun River in Kashmir, India, too, has a fall of 2,480 feet in 80 miles with a minimum flow of 30,000 gallons per second, and a beginning has been recently made to develop the one million electric horse power here represented, a considerable portion of which it is proposed to utilize in the production of nitrate of lime for fertilizer purposes, by combining by means of powerful electric currents the limestone that abounds in this region with the nitrogen of the air, a combination which Danish engineers have shown to be commercially possible, and which inexhaustible product may in time be economically available to replenish the failing powers of the farm lands of America and other countries. Within ten or twenty years also that dream of the electrical engineer, the direct production of electricity from coal without the intervention of the steam engine with its wasteful methods, may be realized. Other means, now unknown, of developing electricity may be wrested from nature's storehouse. Indeed in view of the past progress of electricity, and especially in view of its marvelous progress in the last two decades, theoretically and practically, it requires no great exercise of the imagination to conceive that the time may not be far distant when the universal artificial source of the world's heat, light, and power, will be electricity, and that what is now only surmise as to the sameness of electricity and matter will be demonstrated beyond reasonable doubt. Not only will wireless telegraphy be more perfected than at present, but wireless telephony, and «seeing by electricity» to a distance, may all be practically accomplished. Indeed, it is not even beyond the possibilities that the transference of thought directly from brain to brain with the ether as the medium—the suggestion of which is now regarded as the vagary of a disordered imagination—may then also be realized. In short our successors of twenty-five or thirty years hence may wonder at our obtuseness in not perceiving the obviousness of things which to them may then be self-evident, virtually as we now marvel at the simplicity of our cleverest ancestors in so long failing to recognize the identity of frictional, animal, and voltaic electricity, or the more simple fact that the wind, by them regarded as a phenomenon, is merely air in motion.

William Maver, Jr.,
Author 'American Telegraphy and Encyclopedia of the Telegraph.'

Electricity, Progress of (1800-1907). Before the year 1800, the world's knowledge of electricity was confined to observations on the attraction of electrified pith balls, and to a few facts in regard to electric sparks. Had it not been for lightning, no one could have felt respect for the feeble manifestations of an agency which was destined in less than 100 years to change the channels of trade, to revolutionize methods of communication, and to light the cities of the world. There was another force, too, of which the world in 1800 know something —the force of magnetic attraction. This was useful in the magnetic compass; but it was judged to be insignificant in other respects and totally unrelated to the force of electrical attraction, which was manifested in the case of the pith balls, or to the forces of lightning.

The marvelous development of electricity which we have all seen seems to carry with it the presumption that we have a clearer knowledge of what electricity is than Benjamin Franklin had; but this presumption is not entirely warranted. We certainly know its relations to other forms of motion, such as light and heat, better than he did. We believe that it is a wave motion; but still we cannot fully explain the fundamental experiment of the attraction of two electrified pith balls. To the philosopher, this confession of ignorance of an agency which he can use intelligently, which is highly serviceable, but the origin of which is completely veiled from us, is most suggestive. The question immediately arises, «To what do we owe our command of this mysterious servant?» The answer to the question is this: «We owe our advance in knowledge to the careful verification of phenomena, to the improvements in machinery produced by almost microscopic measurements, and to accurate calculation.»

The steps which led to our present knowledge of the manifestations of electricity can be quickly told. The first was taken by Galvani, who, just before the last century dawned, demonstrated that electricity could be produced by the contact of metals with fluids. His experiments suggested to Volta in 1800 the electric battery. Here was a means by which an electric current could be produced; and Oersted with this current showed a connection between electricity and magnetism. The current in passing through a wire near a compass needle could change the reading of the needle, and the changes depended upon the direction in which the current flowed. Oersted's discovery was made about 20 years after Volta constructed his battery. It was more than 10 years after Oersted that Joseph Henry and Michael Faraday discovered another relationship between electricity and magnetism which involved the possibility of producing currents of electricity by the motion of a magnet. This discovery was the converse of Oersted's; the series of phenomena which it revealed embraced the subject of electro-magnetism, and have led directly to the invention of the dynamo and electric motor. The world, however, did not realize in 1831 the importance of the steps taken by Henry and Faraday. Another 10 years elapsed before the electric telegraph became a success. Then in 1861—30 years from the date of the discovery of electro-magnetism—Paccinnoti invented the armature which Gramme improved, and we had the dynamo and the electric motor. Again, in a little more than 10 years, the telephone came, and the mechanical engineers and the mechanic, thoroughly aroused to the possibilities in the practical employment of electricity, took hold with astonishing energy.

When Tyndall came to the United States in 1870 to deliver lectures on light and electricity, he brought with him 100 Grove cells to produce an electric light for the purposes of demonstration. His assistant was obliged to spend two hours before each lecture in arranging these cells, filling them with acids and scraping the connections, retiring from each encounter almost asphyxiated by the irritating and poisonous fumes of nitrous oxide gas. At the present time no lecturer on science in the halls where Tyndall spoke need spend a moment in providing a source of electricity. It is on tap, so to speak, and can be obtained by touching a button. Tyndall in his highest flight of scientific imagination did not picture a development of electricity which would light the halls in which he spoke, which would convey him to and fro with great speed through the streets which he used in going to them, and would enable him to whisper from Boston across the great prairies of the West to Saint Louis.

The title of his lectures in Boston was suggestive—«Light and Electricity.» Yet his imagination, greater than that of most of his contemporaries in science, failed more completely in the subject of light than in the field of the great practical expansion of electricity. He had no inkling of the coming theory that light is but one of the manifestations of electricity, and in 10 years from the date of his lectures would be so regarded by the leaders of scientific thought. When we reflect upon how much this man saw and how much was withheld from him, a feeling of self-abasement comes over us who are students of electricity. Who can foretell what the next 100 years will unveil?

In reflecting on the rapid advances in the employment of electricity, we are apt to overlook the aid which has been given by the improvements in the mechanic arts. It can be maintained with a great show of reason that the modern lathe, the milling machine, together with the principle of interchangeable parts in machines, have made the dynamo and the electric motor. It is said that Joseph Henry spent months in wrapping wire with cast-off gowns to insulate it for his experimental electro-magnets. Much more powerful magnets can be wound to-day in half an hour. The mechanical means of trying experiments in the practical employment of electricity have multiplied to such an extent that every mechanic can enter a field which once was occupied by only one man in America, Joseph Henry; and can enter it with the most refined appliances in respect to tools and materials. Many of the men who have aided the practical development of electricity have known little of the subject of electricity. Some who have achieved distinction as electricians were ignorant of even elementary laws; but they saw how machines could be operated by what to them was a fluid analogous in its manifestations of flow and pressure to water. Just as men were ingenious in transmitting power by pulleys, belts, and chains, they now became apt in devising circuits, switches, armatures, keys, and the multitude of devices of which one gets a realizing sense in reading the advertisements in the thousand and one papers and periodicals devoted to practical electricity. In a similar manner mariners had become skilful in using the winds, the scientific laws of which they had not studied. The men who have made a lifelong study of electricity are amazed in reading the reports of meetings of electrical engineers to see the photographs of hundreds of men prominent as authorities at such gatherings — men who have suddenly sprung into notice in a field where only college professors once worked. A young man seeking to become an electrical engineer is told to-day, with reason, that he should first become a mechanical engineer. This development of practical electricity through the advancing improvements in machinery will continue, undoubtedly, to be a great characteristic of American industry. The first thought, apparently, of an American mechanic when he looks at a piece of foreign-made electrical apparatus is: "How can I improve it?" He speedily tears it to pieces, puts in screws that are interchangeable, takes out clumsy devices, reduces the weight, removes useless lacquer, and makes a new thing of it — if he does not throw the whole affair on a rubbish heap and proceed to build a machine on an idea which he has grasped.

To the American mechanic, who, having lost his corkscrew, inserts an ordinary screw through a piece of wood in the cork and pulls it, is due much of our national progress in practical electricity. I had occasion lately to buy a modern lathe for the Jefferson Physical Laboratory, and was surprised to find that I should be obliged to wait several months for its delivery. I was informed that 80 per cent of the products of the mills went to France, and Germany, and that foreign labor working 10 hours a day could not compete with American labor working 8 hours on these improved lathes. There is no need of a duty on foreign machinery, for we can trust to the ingenuity of American mechanics to hold the markets.

The efforts of inventors have been turned to electrical devices to such a degree that one has to wait months for a hearing at the Patent Office, and the examiners are so bewildered, apparently, by the claims that they grant patents in the expectation that litigation will settle points which require special study and training to consider properly. In addition to the honest inventor of electrical apparatus, we have another class, who seek to cover the ground of possible advance and to reap the fruits of subsequent study by patient investigators. They stake out claims and sit down, waiting for the worker. This class is not confined to the rank of inventors. There are sensation mongers who make predictions of what will be accomplished some day in electricity, in the hope that when arduous investigators have reached with almost superhuman patience the heights imagined, the suggesters will receive the rewards and the distinction. This is a phase of the use of the scientific imagination which was characteristic of the close of the 19th century. The workers of the next 100 years will find it hard to achieve all these outlined advances. But if the advances are not in the direction anticipated, there are other paths which the well-trained man will open, and which will lead to yet undiscovered domains richer than any hitherto attained.

We obtain a realizing sense of the importance of the advance in electricity when we reflect what changes it has wrought in the United States. The invention of the telegraph has falsified the predictions and estimates of many political economists. Sidney Smith, writing to Earl Grey after the acquisition of California, said that this marked the end of the great American republic, for a people spread over such a vast area, having such diversified interests, and separated by such natural barriers, could not hold together. He did not foresee how strongly a light iron wire could bind San Francisco to New York. The introduction of the ocean cable destroyed the class of East India merchants who went down to the sea in ships. Salem Harbor, in which great sailing vessels rode at anchor or drew up to busy wharves, is now deserted.

No longer can a merchant take extensive ventures in ships' cargoes, for the state of the market is throbbed every instant round the world. Thus a revolution has been caused in commerce by electricity. It is still progressing. When the invention of the telephone was made, it was a common remark that it could not supersede the telegraph, for the latter gave a merchant some evidence of a business transaction, while the telephone left no sign. Notwithstanding this lack of evidence, many kinds of business are now transacted over the telephone. Cotton, for instance, is bought and sold in immense quantities, without any written record of the transactions; for business honor is found to be essential, and without confidence in buyer and seller no transactions are possible. Thus electricity may be said to work for morality.

While there has been a remarkable extension in the communication of intelligence over great distances, there has been a no less remarkable one in the application of electricity to the conveyance of people and goods. Electric railroads are intersecting the United States in almost as many directions as the telegraph and telephone wires. One can travel from Boston to New York by means of such roads, and they bring a desirable element of excitement and the possibility of change of scene to the farmers' wives, once isolated on the dreary farms of New England. Here again electricity becomes an important agent in the spiritual as well as the material life of the nation. Electric motors have not yet superseded steam motors on any of the great lines, and there does not seem to be any immediate prospect of the change; for electric power cannot at present be transmitted economically 100 miles, and the electric motor suitable for the long-distance transmission of electrical power has not been sufficiently perfected. The accomplishment of the substitution of the electric motor for the present locomotive is something left over for the present century. When this substitution is made we shall not be troubled with cinders, and forest fires will be less frequent.

The chief source of electricity is coal, and the century just closed gives no hint of a possible rival to coal unless we except water power. There promises to be a great development in the use of waterfalls in places remote from tidewater, wherever the transportation of coal adds greatly to its cost. Thus, in Switzerland, water power from the numerous mountain sources supplies both light and electrical power for varied industries. The great plant at Niagara Falls for the transmission of power is watched with interest, for if electrical power can be economically transmitted from the falls to New York, the calculations in regard to the diminishing coal supply of the world would lose their ominous character — unless the geologist can show that the world is gradually drying up. The transmission of electrical power has led to a centralization of steam power in great cities. The small steam engines which were scattered about in numerous workshops have greatly diminished in number, and their place has been taken by electric motors supplied with current from a central station. In the same way the gas engines, which at one time seemed to be rising in importance, have largely given way to the electric motor. Thus the plans to pipe gas from central gas manufactories to all parts of a city for power is checked by the extension of a more subtle medium, far more flexible in its applications. No one will use a gas engine if he can obtain an electric motor; for the care and repairs on a gas engine are far more burdensome than in the case of its rival. Moreover, electrical power can be obtained or shut off by merely moving a switch or touching a button. The centralization of power in the physical world seems to be a counterpart of that taking place in the commercial world.

On the great battleships, electric motors are supplanting steam engines and hydraulic engines for moving the turrets, handling the anchors and the heavy guns. This change in the method of distributing power is one of the most remarkable in the development of industry in this century. Steam is still the great moving agency in the world of industry, and electricity is produced by it. Electricity may also be called its servant, for from a central station it generates and transmits what is like a vital fluid to every part of a great city. Steam is still the master of electricity, and there is no prospect of the economical production of electricity by any other agency. This is still the age of steam and not of electricity. The telegraph, the telephone, the electric light, and the electric motor constitute the great achievements in the practical employment of electricity. Great chemical industries are also being established, in which processes are carried on by electricity — notably the manufacture of aluminum, of calcium carbide, of the alkalies, and of carborundum.

In this brief account of the rapid progress in the practical employment of electricity, I have dwelt largely on the aid that the advances in the mechanic arts have given to the development of this employment. The work, however, of the scholars and theorists must not be overlooked. In 1800 there were the one-fluid and the two-fluid theories of electricity — neither of which is now believed by scientific men, though these theories prevailed till nearly the middle of the century. In 1843 Joule established the doctrine of the conservation of energy, by an exact measurement of the equivalent of heat, and this measurement led to the calculation by scientific men of the electrical units, which have made possible the advances by practical men. Without this system of units, founded strictly on the doctrine of the conservation of energy, and the quantitative transformation of steam power into electrical power, practical men would have floundered and business men would have lost heavily in electrical ventures, the expense of which could not have been calculated. After the establishment of the doctrine of the conservation of energy came Maxwell's great hypothesis of the electro-magnetic theory of light. This theory supposes that all forms of energy — light, heat, and electricity — come to us from the sun in the form of electrical and magnetic waves. On this hypothesis, electricity and magnetism are indissolubly connected. One can be transformed into the other — light and heat are electrical. The only difference between electricity and light is in the length of waves in the ether. The century has closed with this grand generalization, the truth of which the entire scientific world is engaged in testing. There is every prospect that it will form the most fruitful hypothesis in the century before us. The experiments of Hertz, who was the first actually to measure waves of electricity, have greatly strengthened the electro-magnetic theory of light. He showed that most of the phenomena of light waves could be repeated with electric waves. They can be reflected, refracted, and polarized. What explanation, however, can we give, on this hypothesis, of the simple experiment of the attraction or repulsion of two electrified pith balls — the apparently insignificant manifestation of electric force with which the century started? How can electro-magnetic waves explain this? It is, indeed, difficult to do this; and to give a reasonable supposition we have to theorize in regard to the molecular structure of matter, and the tension under which it exists when it is polarized — that is, when a positive and negative state, typified by a positively or negatively charged pith ball, exist in the neighborhood of other objects. Our new knowledge of the relations of electricity to other forms of energy is probably destined to come from a careful study of the fundamental experiments of the attraction of electrified bodies. We have already entered on this study with renewed vigor, stimulated by the discovery of the marvelous effect of the X-rays and of radium in penetrating matter and in making gases better conductors of electricity. Thus we started on the new century with investigation of the same phenomena that Benjamin Franklin considered, but with a far wider comprehension of extended relations, with immensely greater experimental resources, and with a well-trained army of investigators.

When we thus survey the progress of electricity we find in the applications of this mysterious source of energy a tendency to continually approximate to the method by means of which all energy is transmitted to us across the ocean of space between us and the sun; that is, to adopt to and fro or alternating electromotive forces instead of steady electromotive forces. The advantage in the employment of such alternating forces resides in the ability to overcome greater resistance when ordinary conductors of electric current are used; and to enable one, so to speak, to submit any transmitting medium like the ether to instantaneous pulses, as in the case of wireless telegraphy. The steady current dynamo cannot generate an electromotive force sufficient to transmit electric power economically to a distance of even 20 miles; while the alternating dynamo, with its transformers, transmits it to more than 100, and the practical distance at present will probably be greatly increased.

One can readily obtain an idea of the method of obtaining high electromotive force from an alternating dynamo by considering the effort of the last 40 years or more to construct a steady current dynamo out of the pulsating to and fro effects produced by revolving a coil between the poles of a magnet; and the effects of such to and fro currents in raising the electromotive force in neighboring coils of wire by suitably increasing the number of turns of wire in such coils. While the effort of inventors was once almost entirely directed to so constructing commutators that the steadiest current might be obtained from the, what can be termed natural, action of a revolving coil in a magnetic field, it is now largely turned to increasing and utilizing the to and fro effect; and when it was discovered that such alternating currents could be economically used with the old Ruhmkorf coil, we immediately had the modern step-up transformer. Such a coil consists merely of a coil of a few number of turns in close proximity to a surrounding coil of a greater number of turns; and it was formerly actuated by rapidly interrupting a battery current through the coil of lesser number of turns. The interrupted currents thus produced currents of higher electromotive force in the coil of more turns; but far less efficiently than the alternating currents from the alternating dynamo.

Now, a current which cannot produce a spark in air of an inch, can, by a suitable transformer, produce a spark of several feet; and such transformers are used in California and in Switzerland to transmit the power of waterfalls 70 to 80 miles. Alternating currents can drive a great variety of electric motors; and the use of such currents in transmitting the energy from reservoirs of water promises to be one of the marked features of the future applications of electricity.

I have said that in our employments of electricity we seem to be getting nearer nature's methods of propagation and transformation of energy. This electric dawn of intelligence is appropriately signalized by the advent of wireless telegraphy, in which the step-up transformer and the electric spark with its high electromotive force is utilized to send electric pulsations through space. Now the cycle seems to be complete; first the electric pulsations from the sun to the earth; then their transformation into sources of energy, and the retransformation into pulsations into the ether.

In the transmission of messages by wireless telegraphy (q.v.) the problem of so tuning the apparatus that it can receive only the message intended for it, and so that it will not respond to every train of waves started in the ether, has not been solved; but advances have been made in this direction. A popular idea of this problem of electric tuning can be gained by considering the fact that the spark from a charged Leyden jar or other receptacle of electricity can be made to evoke a spark from a distant Leyden jar unconnected with the first jar and uncharged, if the distant jar has the same size or same electrical capacity.

Thus we see that the attention of the practical worker in electricity is being directed to the employment of high electromotive forces which, in the time of Benjamin Franklin, was the chief study of electricians. Here is another cycle in the subject of electricity. The study started in the investigation of what is called static electricity; and its most striking manifestation of high electromotive force; and scientific men to-day have returned to this old field and an astonishing new field of inquiry has been opened, leading many to believe that all which appeals to our senses as matter is electrical in its nature. This electrical theory of matter is involved in what is called radioactivity (q.v.). The term radioactive substance is applied to elements or compounds like uranium, thorium, radium, which emit radiations capable of effecting photographic plates and dispelling electric charges. The phenomenon of the dissipation of electricity on charged bodies by X-rays and radioactive substances, together with a similar dissipation produced by ultra-violet waves of light, has led to a great extension of the theory of ionisation. The term ion was applied by Faraday to the constituent parts of a liquid conductor separated by an electric current; the new theory of ionisation of gases supposes that an ion consists of a charged point or centre of a cluster of molecules which travel with it: the process of ionisation of a gas is considered to be the removal of what is called the negative corpuscle from such a cluster of molecules. After the removal of the negative corpuscle a new cluster of molecules is formed with a positive charge. This negative particle is estimated to be one thousandth of the size of the hydrogen atom.

X-rays and the radioactive substances have the property of breaking up the clusters of molecules of a gas, and, by thus separating the negative corpuscle from the clusters, making a gas conducting; for the negative corpuscle carries a negative charge to one metallic terminal in the gas and the positive ion carries a positive charge to the other terminal. It is interesting to notice that the study of this theory of ionisation has been made possible by the use of the earliest instrument used in the study of electricity, the electroscope, which consists of two strips of gold foil suspended close together from a metallic support. When the metallic support is charged the gold leaves diverge, having charges of the same name, being either both positive or both negative. It is estimated that this old instrument is at least a million times more sensitive than even spectrum analysis in detecting minute changes in the condition of matter; and it is also curious to observe that the phenomenon of leakage of electrical charges, which has annoyed and puzzled workers in electricity from the earliest period of the subject, is now largely explained by the phenomenon of radioactivity; a bit of radium, for instance, in a compass case, or a galvanometer case, will dispel any electrification which tends to attract the needle to the side of the case. The new use of the electroscope or electrometer consists in utilizing the old annoyance of electrical leakage by connecting the electroscope to a metallic plate held above another plate connected to the earth and measuring the rate of leakage produced by X-rays or the radiations from radioactive substances.

The English writers speak of a negative corpuscle, and the continental investigators, in general, call both negative and positive carriers of electrical charges electrons. The tendency of thought is to believe that the mass of the electron is not material but is entirely electrical; and many also believe that we are coming to an electrical theory of matter. Such a theory has been advanced by Lamor, Abraham, Drude, and others. It is based upon the phenomenon of electric inertia, or so-called back electromotive force. One can get a popular idea of such electrial inertia by considering the sudden generation of an electromotive force which tends to keep an electric motor driving a trolley car in motion after the generating current is stopped, and also the electromotive force which opposes the starting of the motor when the driving current is applied. Sudden changes in electrical conditions can manifest a phenomenon closely analogous to ordinary inertia of matter. It has been shown that, according to the electromagnetic theory of light, a charge of electricity in motion behaves as if it possessed mass. Kauffman, therefore, has investigated the question whether the mass of the electron is made up of both ordinary matter and electrical matter, or whether it is altogether an effect of electricity in rapid motion. He found by direct experiment that, assuming the charge constant, the apparent mass of the electron increased with the speed. The identification of matter with the movement of electricity is the most remarkable generalization of modern physical science.

JOHN TROWBRIDGE,
Director Jefferson Physical Laboratory, Harvard University.

Electricity, Atmospheric. Experiments have shown that there is always free electricity in the atmosphere, which is sometimes negative and sometimes positive, but most generally positive, and the intensity of this free electricity is greater in the middle of the day then at morning or night, and is greater in winter than in summer. In fine weather the potential increases with altitude at the rate, according to some writers, of about 30 volts per foot. To detect the presence of free electricity in the air a pointed metal rod projecting into the air several feet and connected at its lower end to a gold leaf electroscope may be used. When this rod is projected into the air a few feet the leaves diverge. Kites and balloons have also been used to detect and, so to speak, draw down the free electricity of the air. The origin of atmospheric electricity is still unknown. Some physicists have ascribed it to the friction of the air upon the ground, others to the gradual oxidation of plant and animal life, others again to evaporation, to induction from the sun, and to differences of temperature. Most authorities are agreed, however, that whatever may be the origin of free electricity in the atmosphere the electricity of enormous voltages that disrupts the air and produces the phenomena of lightning (q.v.) is due to the condensation of the watery vapor forming the clouds; each minute vapor drop as it moves through the air collecting upon its surface a certain amount of free electricity. Then as these drops of vapor coalesce into larger drops with a corresponding decrease in the total surface exposed the electric potential rises until it overcomes the resisting power of the air. This remark will be more clearly understood when it is considered that with a given charge of electricity its potential rises as the electrical capacity of the object holding the charge is decreased, which is the case when the minute vapor drops coalesce into larger drops. The similarity of lightning to the electricity developed by an electrical machine was demonstrated by Franklin in his memorable kite experiments.

Electricity, Cause of Death by. As is well known, one of the most important safeguards of the human body against the passage of electrical currents through it is its high degree of resistance. This degree of resistance, however, is subject to a considerable amount of variation. If the skin is dry the resistance is from 5 to 20 times as great as when the skin is wet. From what is known of the amount of electrical current necessary to cause death in man, it is probable that 1,600 volts of electromotive force, of a continuous current, is sufficient to bring about this end, and that an alternating current of half this voltage would probably be fatal. In fact, the general deduction has been drawn from the experiments conducted in electrocution work at the Sing Sing prison, that no human body can withstand an alternating current of 1,500 volts, and 300 has produced death, while for the continuous current it may be necessary that over 3,000 volts may be required to bring about fatal results. Some of the minor injuries due to lightning and electricity are severe burns, paralysis of some of the muscles, deafness, loss of smell and taste, hysterical phenomena, traumatic neuroses. Occasionally blindness has resulted, also insanities of the maniacal type have been known to occur, following lightning stroke. As to the cause of death by lightning and electricity, modern research has shown that there are marked changes in the blood vessels, of a hemorrhagic type, and minute alterations in the nerve cells, but these seem to be secondary to the physiological action that the electrical current has upon the fibres of the heart muscle. The electrical shock brings about a condition of delirium or fibrillary contraction of the heart muscle, causing a stoppage of that organ. This theory of the cause of death at present has the largest number of adherents.

As to what can be done for the treatment of electrical shocks, medical science is still somewhat in doubt. For all practical purposes, death, when it takes place, is instantaneous. The evidence derived from non-fatal cases is of great interest. In these, personal experience has shown that a number of individuals who have been rendered unconscious have recognized in the brief moments of consciousness the experience of a strange sensation. Some have even recognized what the character of the sensation was and the general experience has been that this sensation is not painful but is an exaggeration only of the uncomfortable feeling induced by the faradic battery. It seems more than probable that no painful sensations are felt by those who have died. Recoveries from the shock of electricity or lightning which have been severe enough to bring about unconsciousness are very common. As to the border lines which separate the recoverable from the fatal cases it seems difficult to determine. Promptness in the treatment is imperative. External heat to the body, artificial respiration and cardiac stimulants should be used simultaneously. It is of importance to remember that the body of the patient must not be touched by the rescuer with naked hands, but should be dragged away by his clothing, or removed from contact with the earth by slipping a board under him thus to break the connection with the live wires. Live wires may also be raised by a stick and thus take the body out of the circuit. Artificial respiration (q.v.) by the Sylvester method or by means of the Gibbon's pump should be performed and the body should be surrounded by hot bottles or bricks, and rubbed, and suitable cardiac stimulants should be utilized. Injections of large quantities of hot salt solution into the rectum may be of service and occasionally it may be necessary to infuse normal salt solution directly into the veins. Efforts at artificial respiration should not be discontinued under from three to six hours.

Electricity, Contact Theory of, a theory which assumes that the electromotive force of a voltaic cell, and perhaps the electricity produced by friction, is due to the difference of potential assumed by two dissimilar substances when placed in contact.

Electricity, Diffusion of. Electricity diffuses itself on the surface of a conductor. This we may expect from the self-repelling character of the same fluid. An insulated spherical conductor has two hemispherical cups carefully fitted to it, each attached to an insulating handle. The conductor and its covering are charged with electricity, the cups are then removed, and the conductor is brought near an electroscope. No divergence of the leaves occurs, indicating that none of the electricity has passed into the conductor. If the conductor have a spherical shape, the electricity distributes itself equally over the surface; in other words, the density is the same in every part of the surface. We may conceive the electric fluid to surround the conductor as an ocean of equal depth. If the conductor be a brass disk, the electricity is found in greater quantity at the edges or rim. If it be a brass cylinder with rounded ends, the density is greatest at the ends. If the conductor have the shape of a cone, the density is greatest at the apex, and the sharper the apex the greater the density. Hence the remarkable effect of a pointed body in either drawing, or parting with, electricity.

Electricity, Dissipation of. The gradual loss of electricity from a charged body surrounded by non-conductors, which takes place by means of them, is called dissipation of the electric charge. A charged conductor, for instance, supported on a glass pillar, slowly loses its electricity. This is due partly to the creeping of the electricity along the surface of the glass, which even if it be free from dust and dirt, is never absolutely free from an invisible film of moisture; and partly to the air that surrounds the insulated conductor, the electrified body charging the particles of air with similar electricity and then repelling them, by which means a gradual loss of charge occurs. Experiments extending over a period of several years show this dissipation of electricity does not take place in a vacuum. Coulomb made a careful investigation into the laws of dissipation, by which he was able to allow for it in cases where he could not arrange his experiments so as to be undisturbed by it. Coulomb was led by his experiments to abandon the use of glass as a support for his conductors whenever it was possible, employing instead thin stems of shellac, and sometimes suspending small electrified bodies by well-dried silk fibres. He found that the amount of loss in a given time by means of the particles of air diminishes as the charge possessed by the conductor gets weaker and weaker, the losses in successive equal intervals of time being in geometrical progression.

Electricity, Experimental Researches in, by Michael Faraday (1839–55). A monumental work in the literature of science; not merely recording the results of experiment in what Tyndall called «a career of discovery unparalleled in the history of pure experimental science,» but enriching the record with thoughts, and clothing it in many passages in a style worthy of exceptional recognition. In devising and executing experiments for passing beyond the limits of existing knowledge, in a field the most difficult ever attempted by research, Faraday showed a genius and achieved a success, marking him as a thinker not less than an observer of the first order. In strength and sureness of imagination, penetrating the secrets of force in nature, and putting the finger of exact demonstration upon them, he was a Shakespeare of research, the story of whose work has a permanent interest. He made electricity, in one of its manifestations, explain magnetism. He showed to demonstration that chemical action is purely electrical, and that to electricity the atoms of matter owe those properties which constitute them elements in nature. In language of lofty prophetic conception he more than suggested that the physical secret of living things, the animal and the plant, is electrical. He particularly dwelt on the amount of electricity forming the charge carried by the oxygen of the air, which is the active agent in combustion and the supporter of life in both animals and plants, and only stopped short of definitely pronouncing vitality electrical. He urged very strongly as a belief, to which no test of experiment could be applied, that gravitation is by electrical agency, and that in fact the last word of discovery and demonstration in physics will show that electricity is the universal agency in nature. And among his far-reaching applications of thought guided by new knowledge, was his rejection of the idea of "action at a distance," in the manner of "attraction." If a body is moved, it is not by a mysterious pull, but by a push. The moving force carries it. These ideas outran the power of science to immediately understand and accept. But Maxwell, Hertz, and Helmholtz have led the way after Faraday, to the extent that his electrical explanation of light is now fully accepted. Fifteen years after his death, the greatest of his successors in physics, Helmholtz of Berlin, said in a Faraday lecture in London, that the later advances in electrical science had more than confirmed Faraday's conclusions, and that English science had made a mistake in not accepting them as its point of departure for new research. See LIGHT.

Electricity, Frictional. It was an observation made by the Greek philosopher Thales, 600 years before the Christian era, that, when amber was rubbed, it acquired the property of attracting light bodies. The cause of this attractive power was assigned to a principle to which the name of "electricity" was given — derived from the Greek word for amber. When a piece of wax is rubbed on the coat-sleeve, an attractive power is awakened in it; it is capable of attracting small pieces of light paper or particles of sawdust — a fact well known to every young person. Taking a warm glass tube closed at one end, and rubbing it with silk, the same thing is manifested. It is observed also that after contact with the wax or tube, the light bodies fall away, being seemingly repelled. If a stick of sealing-wax be rubbed with flannel and then balanced on a paper loop suspended by a silk thread and the knuckle be presented to it, the wax will in like manner follow the hand. We have, therefore, the fact that an electrified body attracts or is attracted by an unelectrified body. Another experiment of a simple character may be mentioned. Take a piece of warm brown paper or sheet of foolscap, place it upon a warm board and rub it well over with a piece of india-rubber, it clings to the board; or remove it from the board and apply it to the wall of the room, it adheres to the wall and remains in its position till its electricity is dissipated.

Frictional electricity has been extensively employed in connection with frictional electric machines, in electro-therapeutics. See ELECTRIC MACHINES; FRICTIONAL ELECTRIC MACHINES.

Electricity in Medicine. See ELECTROTHERAPEUTICS.

Electricity in Mining. See MINES AND MINING.

Electrine, (1) The principle of electricity; a kind of matter which manifests electrical phenomena. (2) Made of amber or electrum.

Electro-ballistic, pertaining to projectiles and to electricity. An electro-ballistic apparatus is an instrument for determining by electricity the velocity of a projectile at any part of its flight. The projectile passes through a wire screen, thus breaking an electric circuit and setting in motion a pendulum which is arrested on the passage of the projectile through a second screen. The distance between the screens being known, the arc through which the pendulum vibrates measures the time due to the flight of the projectile between the screens. See GUNNERY.

Electro-ballistic Machines. See GUNNERY.

Electro-biology, the science which treats of the electric currents developed in living organisms; also the department of knowledge which treats of the influence or control over the feelings, thoughts, and actions of a mesmerized person.

Electro-bronze. See ELECTROPLATING.

Electro-chemical Industries. The word electro-chemical is here used to include electro-metallurgy, as there is no generic term for the two subjects. Electro-chemistry may be defined as that branch of science relating to the electrical production of chemical substances and chemical action, or to the generation of electrical energy by chemical action. On the other hand electro-metallurgy is the branch of science that relates to the electrical production and treatment of metals.

Electrolytic Refining of Copper.— The largest and most important of all electro-chemical industries is the refining of copper, which is conducted at many places in this country and abroad. The process of refining copper electrolytically consists in the transfer of copper from the anode to the cathode, by the selective action of the electric current, and in leaving the impurities behind in the anode, electrolyte, and in the slime or sediment.

The material at present subjected to profitable electrolytic refining is crude copper containing from 96 to 98 per cent pure copper, and varying amounts of silver, gold, nickel, iron, arsenic, antimony, sulphur, etc. This crude copper is obtained from various copper ores by smelting, and is cast in iron molds into anode plates, which are about 3 feet long, 2 feet wide, and 1 inch thick, weighing approximately 250 pounds. The cathode plates are of electrolytically refined copper, practically the same in length and width as the anodes, but only 1-20 inch thick. The electrolyte, or bath, in which the plates are suspended is a solution of 12 to 20 per cent copper sulphate, and 4 to 10 per cent sulphuric acid, the latter being introduced to decrease the resistance of the bath which is kept at a temperature of about 40° C. The containing tanks are of wood, usually lined with sheet lead or carefully coated with a pitch compound, and of such dimensions that a distance of about 1 inch exists between the faces of the plates. In some cases the plates are arranged in series, and in others in parallel or multiple, as illustrated. The former has the advantage of requiring electrical connections to be made at the first and last plates only, whereas the parallel system requires a connection at every plate; but in the series system the leakage of current due to the short-circuiting action of the sediment and sides of the tank is from 10 to 20 per cent, so that the parallel is more generally used. The connections between the various plates to the circuit in the parallel systems are made by copper rods, which are run at two different levels along the edges of the tanks, one bar for each set of plates. In some instances these rods are of the inverted V shape, so that the edges will cut through any corrosion which may happen to form at the points of contact. The vats are arranged with respect to each other, so that each is accessible from all sides, and the circulation of the electrolyte is possible. This circulation may be obtained by blowing a stream of air through the electrolyte, but more frequently by arranging the vats in steps, and piping so that the electrolyte may pass from the top of one vat to the bottom of the next, as shown in the illustration. This maintains a uniform density of electrolyte which is necessary for the proper formation of the deposit. The electrical pressure required is from .2 to .4 volts per tank, with a current density of 10 to 15 amperes per square foot of cathode plate surface. The individual vats are connected in series, so that the total voltage required may be approximately the same as that which the generator furnishes, being usually 110 volts. In practice from 400 to 500 ampere-hours are required per pound of copper deposited, the theoretical amount according to Faraday's law being only 386.2 ampere-hours. The loss varies from 4 to 20 per cent according to the system employed.

The cost of refining copper by the electrolytic method is from ¼ to ¾ cent per pound. The following products of refining are marketed: Commercial cathodes, which are sometimes shipped to consumers, but more frequently cast into wire bars, ingots, cakes, or slabs of standard dimensions and weight. They usually assay from 99.86 to 99.94 per cent pure copper. The yield in commercial cathodes is from 97 to 99 per cent of the anodes treated, excluding the anode scrap which varies in weight from 7 to 15 per cent of the original anode in parallel plants, but this scrap is not a loss as it is collected and recast into anode plates. Besides electrolytic copper, most plants secure gold, silver, and nickel salts in the slime, from which the metals are recovered. The electrolytic refineries in the world are now producing copper at the rate of 322,295 tons annually, valued at $96,688,500, with copper selling at $300 per ton, in addition the by-product in recovered gold and silver is valued at $20,000,000 per annum. There are now in active operation 33 electrolytic refineries, with a total generator capacity of 20,000 kilowatts, 10 of these are in the United States, and supply about 86 per cent of the world's product; 6 plants are in England and Wales, producing about 9 per cent; while the remaining plants are on the continent of Europe.

Aluminum.— Practically the output of this metal for the entire world is now produced electrolytically. The only process used on a large scale is that invented independently in 1886 by Charles M. Hall in the United States and by Paul L. V. Héroult in France. This process consists in electrolyzing alumina dissolved in a fused bath of cryolite. The alumina is obtained from the mineral bauxite which occurs abundantly in Georgia, Alabama, and other regions. The natural material, being a hydrated alumina containing silicon, iron and titanium, must be treated in order to drive off the water and eliminate the impurities. Formerly this was accomplished by a chemical process, but now it is effected more simply and cheaply by heating the material mixed with a little carbon in an electric furnace. The impurities are thus reduced and collect as a metallic regulus in the bottom of the mass. This leaves the alumina nearly pure and it may be tapped off while fused or easily separated by breaking it up after cooling. In practice it requires two pounds of alumina for each pound of aluminum produced. The flux or bath in which the alumina is dissolved consists of cryolite, a natural double fluoride of aluminum and sodium ($Al_2F_6.6NaF$) found in Greenland. This is melted in a large carbon-lined, sheet-iron tank which constitutes the negative electrode, a group of suspended carbon rods forming the positive electrode. A current of several thousand amperes at 6 to 7 volts is used. Only a portion of this voltage is required to decompose the alumina, the balance amounting to about 4 or 5 volts represents the heat produced which keeps the bath melted. The passage of the current causes the aluminum to deposit on the bottom of the tank as a fused metal, being drawn off periodically. The oxygen set free combines with the carbon of the positive electrodes and passes off as carbonic oxide. The reaction is $Al_2O_3+3\ C=2Al+3\ C\ O$. About one pound of carbon is consumed for one pound of aluminum produced. When the alumina becomes exhausted from the bath, the voltage rises and lights a lamp shunted across the electrodes, thus giving notice that more material is needed. Each electrical horsepower produces about one pound of aluminum per day of 24 hours. According to Faraday's law the weight of aluminum deposited by 1,000 amperes is .743 pound per hour. The actual yield of metal by the Hall process is about 85 per cent of this theoretical amount. The total power used by the various works employing the Hall process, is very large and amounts to more than 15,000 horsepower in the United States and Canada. The total power employed in European plants operating under the Héroult patents is nearly as great. The metal when drawn from the tanks is cast into rough ingots which are afterwards remelted and converted into commercial shapes, such as sheets, rods, wires, etc.

Electrolytic Production of Caustic Soda.— The production of caustic soda ($NaOH$) and chlorine (Cl) by the electrolysis of common salt ($NaCl$) is readily realized experimentally ($NaCl + H_2O = NaOH + Cl + H$), but its successful accomplishment on a commercial basis is difficult because of the secondary reactions which take place, forming a mixed product of caustic, salt, and hypochlorite of soda. These difficulties are avoided by separating the caustic soda or sodium that is formed, either by a porous diaphragm, by drawing it off as soon as formed, or by absorbing the sodium deposited in mercury or melted lead.

The two most successful systems for the electrolytic production of caustic soda and chlorine from common salt, are the Castner-Kellner and the Acker processes, one operating at moderate temperatures (40° C.) and the other at high temperatures (850° C.). The Castner process employed in this country at Niagara Falls is as follows: The electrolytic tank consists of a slate box, 4 feet long, 4 feet wide, and 6 inches deep, the joints being made by means of a rubber cement. Two slate partitions reaching within 1-16 inch of the bottom (under which are grooves) divide the cell into three compartments, each 15 inches by 4 feet, sealed from each other by a layer of mercury covering the bottom of the tank to a considerable depth. The outside chambers through which the brine is passed are provided with carbon anodes, shaped like a rail section, the broader flange being placed about half an inch above the mercury. These compartments are provided with tight covers and exhaust pipes of rubber and lead, to lead the chlorine away. The central compartment has an iron cathode, of 20 upright strips, and is supplied with pure water, which is drawn off whenever its specific gravity increases to 1.27 due to the presence of the manufactured caustic, while the liberated hydrogen is led from this chamber by means of pipes and used as a fuel for the concentration of the caustic. The tank is pivoted at one end on a knife blade and rests at the other on an eccentric, which raises and lowers that end of the tank about half an inch every minute and causes a circulation of the mercury between the outer and middle compartments. The current passes into the outer chambers, splits up the sodium chloride (common salt, NaCl) into sodium and chlorine (Na and Cl), the latter is liberated at the carbon anodes and passes through the exhaust pipe to the absorption chambers where it combines with slacked lime to form bleacning powder. The sodium combines with the mercury forming sodium amalgam, which by the tilting of the tank passes to the centre chamber, where it serves as the anode, and combines with the water to form caustic soda (NaOH) and hydrogen (H), which appears at the iron cathode. Each of these tanks uses 630 amperes at 4.3 volts. The theoretical voltage required is but 2.3, the remainder being utilized in overcoming the ohmic resistance of the electrolyte and in keeping it warm. The output of this process per horsepower per day is 12 pounds of caustic and 30 pounds of bleaching powder for each cell. The product of this process contains from 97 to 99 per cent caustic, 1 to 2 per cent sodium carbonate, .3 to .8 per cent of sodium chloride, and traces of sodium sulphate and silicate of sodium.

The Acker process, also used at Niagara, to obtain caustic soda and chlorine from salt, is similar to the Castner-Kellner process just described, but differs in that it employs molten lead in place of mercury as a seal, fused salt instead of brine as the electrolyte and operates at a temperature of 850° C. which is required to maintain the fused condition of the electrolyte. The containing tank is a cast iron vessel 5 feet long, 2 feet wide and 1 foot deep, the sides above the molten lead being covered with magnesia so that the current must pass from the carbon anodes to the lead which acts as the cathode. At one end of the tank is a small compartment separated from the remainder of the vessel by a partition dipping into the lead to such a depth that nothing but this fused lead can pass from one compartment to the other. In the smaller compartment the lead is subjected to a stream of steam, which acting upon the lead sodium alloy forms caustic soda and liberates hydrogen. At various intervals the caustic, which is in a fused state, is drawn off and allowed to solidify, thus avoiding the evaporation of the water which is necessary in the Castner-Kellner process. The current employed per vessel in the Acker process is 2,100 amperes at from 6 to 7 volts, of which energy 54 per cent is used in chemical action, and the remainder in maintaining the temperature.

Potassium Chlorate is produced electrochemically in considerable quantities, both here and abroad. The Gibbs process, used at Niagara Falls, consists in the electrolysis of potassium chloride solution, using a copper or iron cathode and a platinum anode. The current density is high, being 500 amperes per square foot of anode. Each cell uses about 4 volts, of which 1.4 is required to convert chlorid to chlorate, and the remainder produces the heat that maintains the electrolyte at from 50° to 70° C., which is necessary for the proper reaction.

Electrolytic Chemical Effects, such as bleaching, have been produced through the action of chlorine or other matter set free by an electric current. It is possible in this way to cause substances to act while in the nascent state, and therefore more powerful. Disinfecting and deodorizing of sewage has also been accomplished in a similar manner.

Calcium Carbide.—This compound is produced by the electrothermal process, invented by Willson in 1891, the total output throughout the world being about 300,000 tons in 1902. Its value lies in the fact that 1 pound of this substance mixed with water produces theoretically 5.5, and actually about 5 cubic feet of acetylene, equivalent in illuminating power to about 70 cubic feet of ordinary gas. The reaction producing acetylene is $CaC_2 + H_2O = CaO + C_2H_2$. Various forms of electric furnace have been employed in the production of calcium carbide. One type invented by King and represented in the illustration, consists of an iron car A, which holds the materials and carbide at the same time acting as one electrode. It can be run into place or removed as desired, and being provided with trunnions its contents may be tipped out. The other electrode consists of a bundle of carbon plates carried by a heavy rod C, composed of a copper strip strengthened by iron side bars. The material, which is fed through the channels G F, consists of a mixture of 1 ton of burnt lime and ¾ ton of ground coke to produce 1 ton of carbide, the reaction being $CaO + 3C = CaC_2 + CO$. An arc is first formed between the electrode C and the floor of the truck. The resulting high temperature converts the mixture into carbide, the electrode being gradually raised and more material added until the car is nearly filled with the product, when it is run out and replaced by another. At Niagara Falls a rotary form of furnace invented by C. S. Bradley is used, being operated continuously and producing about 2 tons in 24 hours when supplied with 3,500 amperes at 110 volts, or about 500 horsepower. Since no electrolytic action is required an alternating current is employed.

Barium Compounds.—The principal source of barium is barite or heavy spar, the natural sulphate. Processes for converting this material into barium hydrate, nitrate, chlorid and other soluble salts have been invented by C. S. Bradley and C. B. Jacobs. They consist in melting in an electric furnace a mixture of barium sulphate with a small quantity of carbon. If one part of carbon to 5 parts of sulphate be present, the sulphate would be all reduced to sulphid, but with one fourth as much carbon a corresponding amount of sulphid is produced which reacts upon the unchanged sulphate and the oxid is obtained, the two reactions being as follows:

$$BaSO_4 + 4C = BaS + 4CO \text{ and}$$
$$3BaSO_4 + BaS = 4BaO + 4SO_2$$

The carbonic oxide (CO) and sulphurous acid (SO_2) pass off as gases, the latter being used to make sulphuric acid. The fused barium oxide (BaO) is tapped off, cooled, broken up and then digested with hot water. On cooling, barium hydrate [$Ba(OH)_2,8H_2O$] crystallizes out. This is used in extraction of sugar, making of white paints, "softening" water, and producing other barium compounds.

Cyanides of Potassium and Sodium are produced electro-chemically by the process of C. S. Bradley, C. B. Jacobs and others. A mixture of barium oxide or carbonate is heated in an electric furnace to produce barium carbide (BaC_2). While the mass is still hot, nitrogen gas is passed through it and barium cyanide is formed, the complete reaction being:

$$BaO + 3C + N_2 = BaC_2N_2 + 3CO$$

The barium cyanide thus produced is treated with sodium carbonate, the result being a mixture of sodium cyanide and barium carbonate. The former is separated by dissolving it in water, the insoluble barium carbonate being used over again. Potassium cyanide is made in a similar manner, and either salt is suitable for gold extraction and other purposes for which cyanides are employed.

Carborundum is a commercial name for carbon silicide, which is produced in large quantities according to the inventions of A. G. Acheson and his assistants. It is used as an abrasive, being hard enough to scratch ruby. It is formed by intensely heating in an electric furnace, a mixture of 3½ tons of ground coke, 6 tons of sand, and about 1½ tons of sawdust and salt, the yield being 3 or 4 tons of crystalline carborundum and about as much more of the amorphous material. The furnaces used at Niagara Falls consist of simple brick hearths 16 feet long and 6½ feet wide, with solid brick walls at each end, about 2 feet thick and 6 or 8 feet high as illustrated. In the middle of each of these walls there are iron frames through which the current is led to a core composed of carbon, weighing about 1,000 pounds, and extending the entire length of the furnace. This core is raised to a very high temperature by passing through it for 36 hours, an alternating current of about 1,000 electrical horsepower at 190 decreasing to 125 volts. The heat from the core permeates the mass and converts it into carbon silicide which is broken up after the furnace has cooled and used to make hones, wheels for grinding, etc.

Artificial Graphite.—As an outgrowth of the carborundum process, Mr. Acheson has developed on a large scale the manufacture of artificial graphite. The material ordinarily used is anthracite coal ground to about the size of rice, which is raised to an exceedingly high temperature in a long electric furnace in the form of a trough about 2 feet square and 30 feet in length. An alternating current of about 1,000 horsepower at 220 to 80 volts is passed for 20 hours longitudinally through the mass, which becomes converted into graphitic carbon. Another line of manufacture consists in graphitizing moulded articles of carbon, such as blocks and rods for electrodes, which are piled in a furnace similar to that described for converting coal into graphite. By using different materials and conditions the two methods produce different kinds of graphite suitable for lubrication, crucibles, pencils, stove polish, electrodes, etc.

Electric Smelting.— One of the earliest commercial processes in electro-chemistry was that devised by E. H. and A. H. Cowles in 1884. A mixture of about 2 parts of alumina, 1 or 2 parts of granulated copper and 1 or 2 parts of carbon was introduced in a brickwork chamber. Bundles of carbon rods inserted at the ends formed the electrodes between which a current of 3,000 amperes at 50 volts was maintained. At a very high temperature the alumina was reduced ($Al_2O_3 + 3C = Al_2 + 3CO$) and the resulting aluminum combined with the copper to form aluminum bronze.

Iron and Steel can be produced by reducing iron ore with carbon in an electric furnace. For example, a mixture of magnetite and carbon can be heated by passing a current through it as in the Cowles aluminum bronze process, through a carbon core in contact with the material as in the carborundum process, or by the action of an arc as in the carbide process. The reaction is simply $Fe_3O_4 + 4C = 3Fe + 4CO$. Pure (that is wrought)iron, cast iron or steel may be produced, depending upon the proportion of carbon. The chief advantages are the directness of the process, and the fact that the impurities in the fuel (sulphur, silicon, etc.) are not introduced. On the other hand it is a question whether the electric furnace can compete in economy with the blast furnace and Bessemer converter.

Alundum, the trade name for artificial corundum, is an abrasive made by a process due to C. B. Jacobs. Bauxite, a natural hydrated alumina, the same material as used in the Hall aluminum process, is calcined to drive off the water and then fused in an electric furnace using 80 volts and 2,000 amperes of alternating current. The mass is allowed to cool and then broken up, having a blue or red color and being of the nature of sapphire and ruby, in fact it is chemically identical with these gems. It makes excellent emery wheels, emery paper, etc.

Nitrogen and Oxygen Compounds are produced by the electrical process of C. S. Bradley, and D. R. Lovejoy. The apparatus consists of a cylindrical chamber through which a number of electrodes, E E, are introduced as illustrated. The ends of the radial arms A A carried by a revolving spindle S pass very close to the electrodes. A pressure of 6,000 to 8,000 volts maintained by the generator G, between the arms and the electrodes, produces arcs 4 to 6 inches long that are drawn momentarily. The current is unidirectional, but being pulsating, an induction coil C in series with each electrode, cuts the current down to about .005 ampere per arc. There are 180 stationary electrodes in each chamber, and as the arms revolve 500 or more times per minute, at least 18,000 arcs are formed in each chamber in that time. Ordinary air, after being dried, is passed through the chamber, where the arcs cause a certain percentage of the nitrogen and oxygen to combine. This compound absorbed in caustic soda forms sodium nitrite or nitrate, with potassium hydrate it forms potassium nitrite or nitrate, and by absorption in water nitric acid may be produced.

Ozone is produced in chambers through which a silent electric discharge is caused to pass from a static electric machine, induction coil or very high voltage transformer. If air circulates through the chamber a certain portion of its oxygen is converted into ozone.

Organic Compounds, such as dyestuffs, vanillin, iodoform, chloroform, are also produced electrically. See ELECTRO-CHEMISTRY; ELECTRIC FURNACES; ELECTROLYSIS; METALLURGY.

F. B. CROCKER,
Columbia University.

Electro-chemical Series, the arrangement of a number of chemical substances in the order of their affinity for the positive or for the negative pole of a battery.

Electro-chemical Society. The American Electro-chemical Society was founded in Nov. 1901, at Philadelphia. The second general meeting was held at Niagara Falls during October 1902, and the third in New York in 1903. The society has now about 500 members. It was organized to promote the interests of theoretical and applied electro-chemistry and electro-metallurgy, and its influence has already been felt in that new and rapidly growing industry. Its membership includes most of the prominent electrical engineers and electro-chemists in this country.

Electro-chemical Telegraph, a telegraph which records signals upon a paper sheet or strip moistened with a chemical solution, which is decomposed by the electric current. See TELEGRAPHY — *Automatic Chemical System.*

Electro-chemistry, that branch of chemistry in which the reactions that occur are instituted or maintained, either directly or indirectly, by electrical agencies. The electric furnace (q.v.) affords an example of the indirect application of the electric current to the manufacture of chemical substances; the adjective «indirect» being applied in this case, because in most of the uses to which the electric furnace is put, the current does not itself perform chemical work, but merely serves to produce the high temperatures that are essential to the chemical reactions that are desired. The highest temperatures that were known previously to the invention of the electric furnace, were those that prevail in the flame of the oxy-hydrogen blow-pipe. The temperature that is attainable by the combination of oxygen and hydrogen, however, is limited by the fact that water-vapor (which is the product formed by the combination of these gases) has a definite, though high, temperature of dissociation, above which it cannot exist as water-vapor, but is resolved again into a mixture of hydrogen and oxygen. Hence this temperature of dissociation cannot be exceeded by the oxy-hydrogen blow-pipe flame, since the gases cease to combine when it is attained. In the electric furnace no such theoretical limit exists. The heat is produced, here, by the conversion of the electrical energy into heat energy; and so long as the generation of heat within the furnace exceeds that which is lost by radiation in other ways, the temperature will continue to rise without limit, or until some essential part of the furnace itself melts or volatilizes. Calcium carbide is formed, at these high temperatures, by the direct union of carbon and lime, and is now made, commercially and in large quantities, by this process; but the combination does not occur at the comparatively low temperature of the oxy-hydrogen flame. Carborundum (carbide of silicon) is also made in the same way.

The direct action of electricity in promoting chemical combination is exemplified by the «ozonizer,» which consists of a pair of glass tubes, placed one within the other, and separated by an annular space. Coatings of tin-foil, or of something equivalent to it, are applied to the inner surface of the inner tube, and also to the outer surface of the outer one; the apparatus being then connected with the terminals of an induction coil, after the manner of a Leyden jar. The annular space between the two tubes is thus exposed to a rapid alternation of electric stresses, though no actual sparking takes place through it. Gases which ordinarily show no tendency to combine with each other often will do so with greater or less readiness when mixed in suitable proportions and exposed to the alternating electric stress (known, technically, as the «silent discharge») in the annular space between the two tubes. The apparatus is called an «ozonizer,» because it is chiefly used for the production of ozone from oxygen, or from air; but it has also been used, in the laboratory, for the production of many other substances. As an example of the singular power of the silent electric discharge to effect syntheses, it may be noted that hydrogen and carbon dioxid, when mixed in the proper proportions, combine directly under its influence, with the formation of formic acid. $CO_2 + 2H = H.COOH$. The combination does not occur explosively, but, like most of the other combinations under the influence of the silent discharge, it progresses quite slowly and uniformly.

The synthesizing action of the silent electric discharge has a great theoretic interest, but it has never been found to be of any particular importance for the commercial production of chemical substances. Electrolysis of dissolved salts has been found to be far more promising, and a corresponding amount of attention has been given to it. (See ELECTROLYSIS.) A large part of the copper of commerce is now refined by electrolysis, and practically all of the aluminum that is produced is reduced to the metallic form by this same method. (See ALUMINUM; COPPER; ZINC.) Common salt (sodium chlorid) is electrolyzed in large quantities in connection with the manufacture of bleaching powder (q.v.) and caustic soda; the chlorine that it contains apearing in the form of bubbles at the anode, while the sodium goes to the cathode, where it combines with a molecule of water at the instant of its liberation, generating sodium hydroxid, or caustic soda. The free chlorine thus obtained is used in the manufacture of bleach, or of chlorate of potassium or chlorate of sodium; and the caustic soda that is simultaneously formed at the cathode may be recovered and brought into marketable form. In mills where wood pulp is manufactured in large quantities it is not uncommon to meet with auxiliary electro-chemical plants for the manufacture of the bleach liquor that is needed for whitening the pulp; but in these plants no attempt is usually made to recover the caustic soda, nor to utilize it in any way, since the pulp-mills are often far from any market at which the soda could be sold, and the freight rates would make its recovery unprofitable. In regions that are more favorably situated, however, caustic soda is now produced by the electrolytic method in vast quantities. Barium hydrate is also manufactured in quantity by electrolysis, and its market price has been materially reduced, in consequence, within the past few years. Great attention has been paid to the electrolysis of organic substances in recent times, especially in Germany, and results that are of much value have already been obtained. Several of the great chemical works of Germany and Switzerland are now preparing certain of the coal-tar colors by electrolysis (q.v.) on a commercial scale; but the details of the processes are not made public. Goppelsroeder has given special attention to the electrolytic preparation of these bodies, and with an encouraging measure of success. Among his results of fundamental importance we may specially note the preparation of alizarin by the electrolysis of anthraquinone and caustic potash, and of aniline black (together with other coloring matters) from aniline.

The literature of electro-chemistry and of electrolysis is already extensive, and periodicals devoted to the subject, as well as societies for its study and further development, exist in several countries. The American Electro-Chemical Society, which now includes most of the workers in this field in the United States, was organized 1 Nov. 1901 in Philadelphia. Some idea of the magnitude to which the electro-chemical industry has grown may be had from the fact that the value of the annual output of electro-chemical products, in the United States alone, exceeds $100,000,000. Germany is second, with an annual output of more than $15,000,000.

More or less information on the subject of electro-chemistry and electrolysis may be had in any work on physical chemistry. A valuable and suggestive mass of material, bringing the subject down to about 1889, will be found in Tommasi's ‹Traité d'Electrochimie.› An excellent elementary exposition of the principles of electro-chemistry is given in Lüpke, ‹The Elements of Electro-Chemistry Treated Experimentally›; and Löb's ‹Electrolysis and Electrosynthesis of Organic Compounds,› translated into English by H. W. F. Lorenz, is equally good for the special applications to organic chemistry. See ELECTRO-CHEMICAL INDUSTRIES.

Electro Chronograph. See CHRONOGRAPH.

Electrocides, the amber islands of Greek mythology, at the mouth of the river Eridanus. The name was applied also to the islands on the northern coast of Europe.

Electroculture of Plants, the employment of electric light in agriculture and horticulture. It was determined at the Agricultural Experiment Stations of Cornell University and of West Virginia, in experiments made with the arc and the incandescent lights, respectively, that certain crops are forwarded by the light. The most remarkable instance is that of lettuce, which was brought to maturity from 5 to 10 days earlier than other plants grown in the same house, and under otherwise identical conditions. This discovery has led to the commercial application of the arc light, if not of the incandescent also, to the forcing of lettuce under glass in several of the larger New England forcing houses with the result that a gain of about three weeks' time is calculated upon for the season, thus enabling the gardener to devote his benches to one more crop than formerly, or to follow his lettuce crops with cucumbers, the favorite successor, much earlier than would otherwise be possible. Several flower crops, such as Easter lilies and sweet-peas, have been experimented upon with the result that they were forced into bloom several days in advance of others grown without the stimulus. In such cases the plants are always grown without the light until within about a month of maturity, when the light is applied for about half the night. It has been found that unless the light pass through a glass globe or pane there is a noticeable «scorching» of the foliage or flower. It is concluded that this is due to the action of the ultra-violet rays of the spectrum rays, which do not pass through the glass.

Consult various bulletins of the Massachusetts Hatch, Cornell University, and West Virginia, Experiment stations. See ELECTRIC VEGETABLE GARDENING.

Electrocution, capital punishment by the agency of Electricity. See ELECTRICITY, CAUSE OF DEATH BY.

Electrode (Greek, *hodos*, «a way»), a term introduced by Faraday to denote the conductors by which electricity either enters or leaves an electrolytic bath or solution. He termed the electrode by which the current enters the bath, the anode (positive terminal), and the electrode by which the current leaves, the cathode, sometimes spelled kathode (negative terminal). The terms anode and cathode have been introduced generally in metallurgical practice, and also in connection with Crooke's tube, X-ray work, and the term electrode has become common in the more extended sense of signifying either of the terminals of an electric source, instrument, or electrolytic bath or cell.

Electro-dynamics, that branch of electrical science which treats of the attractions and repulsions exhibited between wires or other conductors along which currents are passing. If two wires are parallel they will attract each other when currents are passing the same way along them both, and will repel each other when the currents are opposite. If the wires are inclined to each other at any angle there is not only an attraction or repulsion but a still more marked tendency to rotation which is not satisfied till the wires have become parallel and the currents flow in the same direction along them both. When there are only two straight wires these forces are feeble and require delicate apparatus for their exhibition, but by employing coils of wire the forces are multiplied and an instrument constructed on this principle called the electro-dynamometer has been much employed for the measurement of currents. The basic principles of electro-dynamics were discovered by Ampere in 1821 by many ingenious experiments, the results of which he expounded in a series of statements known to this day as Ampere's Laws.

Electro-dynamometer, an instrument used for the measurement of electric currents by means of the mechanical forces which they exert on each other. It contains two coils of wire, one fixed and the other movable; the latter being either larger or smaller than the other so as to be able to pass either outside it or through it. The coils are set up in vertical planes at right angles to each other; they have a common centre and round the common central diameter of the coils the movable one can revolve. The terminals of the movable coil dip in cups of mercury, one of which is in connection with one end of the fixed coil and the other with one of the binding screws of the instrument. The other binding screw is in connection with the other end of the fixed coil. Hence, when the two binding screws are connected with a battery or other source of electricity, the current has to pass through both coils, and in such a manner that the current will circulate the same way round both coils. Its effect is exhibited by a tendency in the movable coil to set its plane in coincidence with that of the fixed coil. This tendency is resisted by mechanical means provided for the purpose — usually by the torsion of a wire from the end of which the movable coil hangs, and the measurement is usually made by applying torsion till the planes of the two coils are at right angles. See ELECTRIC ALTERNATING CURRENT; ELECTRO-DYNAMICS.

Electro Kinetics. See ELECTRIC DIRECT CURRENT; ELECTRIC ALTERNATING CURRENT; ELECTRICITY.

Electroly'sis, in the strict sense, is the resolution of a fluid into its proximate constituents by the direct chemical action of the electric current; but the word is now commonly applied to all chemical operations, whether analytic or synthetic, which are performed by the direct action of the current. The phenomena that occur in the electric furnace (q.v.) are often incorrectly said to be "electrolytic"; but in most cases they are not so, electricity being used, in this instance, merely as a means for the production of high temperatures. Most of the chemical reactions that are observed in the electric furnace would occur equally well without the use of electricity, if the same high temperatures could be realized by other means; though in some cases, as in the reduction of metallic aluminum by the Hall process (see ALUMINUM), the fundamental operations really are electrolytic, and the high temperature is required merely to keep the electrolyte in the fluid state. The first recorded observation of a distinctively electrolytic action was made in 1800 by Nicholson and Carlisle, who observed that when the terminal wires of a galvanic battery are immersed in water, bubbles of gas arise from them. The correct explanation of this phenomenon was shortly afterward given by Sir Humphry Davy, who carried out an exhaustive series of experiments which laid the foundations for the practical knowledge of electrolysis that we have to-day. Davy demonstrated the tremendous importance of the electrolytic method of analysis, by applying it to study of the alkaline earths and the caustic alkalies. The nature of these substances was not previously understood; but he proved them to be the oxids of previously unknown metals, and prepared the metals themselves in the free state. By passing the electric current through melted potash, for example, he found that bubbles of free oxygen gas were liberated at one of the electrodes, while silvery globules of what is now known as potassium appeared at the other electrode. A few days later he isolated the metal sodium in the same manner, by the electrolysis of soda; and he succeeded, afterward, in demonstrating the compound nature of lime and magnesia also, by the aid of the electric current. As may be imagined, the new method aroused the keenest interest in the scientific world. Napoleon, then at the zenith of his power, offered valuable prizes for discoveries along the same lines, and had large voltaic batteries constructed, in order that French investigators might have every opportunity to carry on the work. The two great Swedish scientists, Berzelius and Hisinger, discovered many new phenomena, and elaborated a general theory of the constitution of chemical substances, based largely upon their behavior under the action of the electric current; and Faraday (q.v.) established the fundamental quantitative laws that hold true in electrolytic decomposition.

Some slight evidence has been adduced which indicates that in certain cases the passage of electricity through solids may be accompanied by slight chemical changes of an electrolytic nature, and phenomena allied to those of electrolysis have been observed in connection with high-tension electrical discharges through gases (see Thomson, 'Recent Researches in Electricity and Magnetism,' chapter 2 and appendix); but in general, electrolysis is observed only in liquids. All liquids may be divided into three classes, according to their behavior when the attempt is made to pass electricity through them. In the first class belong mercury and the other molten metals, which conduct the current readily, and without any noticeable chemical effects. In the second class belong such substances as carbon disulphid and absolute alcohol, which do not conduct the current at all, and hence are not subject to decomposition by it. Absolutely pure water probably belongs to this class, though it becomes a conductor when the smallest quantities of certain impurities are present. Water that is ordinarily called "pure" conducts electricity fairly well, but its conductivity falls off as the purity increases, and Kohlrausch and Heydweiler have shown that water that is distilled in a vacuum, and collected in a glass vessel which has been kept full of distilled water for 10 years in order to dissolve out all the soluble constituents of the glass, has a conductivity almost too small to be measured. The third class of liquids includes all those (such as aqueous solutions of the various metallic salts) in which electric conduction is always accompanied by a definite chemical change. In the present article attention will be confined to this third class, whose constituents are known as «electrolytes,» and in which the current is said to flow by «electric conduction.»

It is necessary, in the discussion of electrolytic phenomena, to distinguish between the primary effects of the passage of the electric current through an electrolyte, and the various secondary effects that may also occur; and while it is not always easy (nor even possible), in actual work, to determine, definitely, what the primary effects are, one or two cases may be cited which will serve to illustrate the difference between primary and secondary effects sufficiently for present purposes. If a current of electricity is passed through melted chloride of lead, $PbCl_2$, the primary effect of the electrolysis is the resolution of the chlorid into its constituent elements, in accordance with the equation $PbCl_2 = Pb \times 2Cl$, metallic lead being deposited upon the cathode. If carbon electrodes are used, free chlorine will also appear at the anode; but if platinum electrodes are used, little or no free chlorine will be obtained, because the gas will combine with the metal of the anode in this case, with the formation of platinum tetrachlorid. The combination of the chlorine with the platinum is an example of secondary action. Again, in the electrolysis of sulphuric acid, H_2SO_4, it is known that the primary effect is the resolution of the acid into hydrogen and the radical «sulphion,» SO_4, in accordance with the equation

$$H_2SO_4 = 2H + SO_4.$$

The hydrogen goes to the cathode, where it is set free. The sulphion goes to the anode, but it is not capable of existence in the free state, and hence some secondary reaction is inevitable. If the acid is dilute, and the anode is of platinum, the sulphion combines with water at the instant of its liberation, according to the equation $SO_4 + H_2O = H_2SO_4 + O$. In this case, therefore, the effect of the secondary action is to regenerate a molecule of sulphuric acid, and simultaneously set free an atom of oxygen; and the evident products of the electrolysis are merely hydrogen and oxygen, which appear at the cathode and anode, respectively. If the acid is concentrated instead of dilute, the secondary action just described will still occur to some extent so long as the acid is not absolutely anhydrous, but free sulphur dioxid is also liberated at the anode in this case; and finally, under certain conditions, sulphur itself may be obtained at the cathode. The secondary chemical changes that occur in an electrolytic cell depend upon the nature of the electrolyte, upon the concentration of the solution, upon the temperature, and upon the strength of the current to which the primary chemical effects are due. They are often complicated and of an unexpected nature; and it is to the study of these secondary changes, under varying conditions, that industrial electrolytic chemistry must look for its further advancement.

No primary chemical changes whatever are to be observed, in an electrolytic cell, save at the electrodes; though secondary changes may occur elsewhere, on account of the diffusion of the immediate products of decomposition through the liquid of the cell. The primary changes do not depend in the smallest degree upon the size of the electrodes, nor upon any other factor save the total quantity of electricity that passes through the cell. If a series of cells, containing electrodes of various sizes and filled with a given solution in different states of concentration, be placed simultaneously in the same circuit, so that the same identical current traverses them all, the primary products of decomposition will be the same in all, both in nature and in quantity. Moreover, if the same experiment be repeated when the several cells are filled with solutions of diverse natures, the primary products will necessarily be different from one another in kind, but when their quantitative relations are examined, it is found that they are liberated in precisely equivalent proportions. For example, if one cell contains chlorid of sodium and another contains nitrate of silver, then the quantity of chlorine liberated in the first cell is precisely sufficient to unite with the metallic silver liberated in the second one, so as to produce chlorid of silver without excess of either chlorine or silver. This statement needs one simple qualification, however, before it can be applied universally. If the two cells considered contain mercuric nitrate, $Hg(NO_3)_2$, and mercurous nitrate, $HgNO_3$, respectively, then for every ounce of mercury that is deposited from the mercuric salt, two ounces will be deposited, simultaneously, from the mercurous salt. Obviously the quantities of Hg and of NO_3 that are liberated in the two cases cannot both be the same; and it is the NO_3, and not the Hg, which is liberated in equal quantities. In general, the «chemical equivalent» of an element is defined as the atomic weight of the element, divided by the valency that the element has, in the compound under consideration; and the quantities of the various elements that are liberated by a given quantity of electricity are proportional to the «chemical equivalents» of the elements, as they occur in the compounds that are submitted to electrolysis, rather than to the «atomic weights» of these elements. The number of grams of an element that are liberated, electrolytically, by one C. G. S. unit of electricity, is called the «C.G.S. electro-chemical equivalent» of that element. The electro-chemical equivalent of silver is known by experiment to be about 0.01118; and the electro-chemical equivalent of any other element may be found from this by simple proportion, as explained above. For many purposes it is more convenient to know what weight of a given element will be deposited in one minute, by a current whose intensity is one ampere. This is given, in the accompanying table, for the more important elements. The elements are here divided, for convenience, into those that are electro-positive, and those that are electro-negative; the former being those that usually appear at the cathode, and the latter those that usually appear at the anode. This classification is not very valuable in the case of complicated compounds, but it answers for the simpler ones. The data given in the table refer to the primary products of decomposition; but it is sufficiently evident that they apply equally well, so long as the visible product of the decomposition is all of one kind, whether it is primary or secondary. In the electrolysis of sulphuric acid, for example, «sulphion» is the primary product at the anode; but sulphion is incapable of independent existence, and the only visible product at the anode is oxygen, so long as the acid is sufficiently dilute. In this case the quantity of oxygen that is liberated can be computed precisely as though the oxygen were itself the primary product. When, as in the electrolysis of concentrated sulphuric acid, more secondary products than one are obtained, the

GRAMS LIBERATED PER AMPERE PER MINUTE.

case is more involved. In general, however, we must remember that it is only with reference to the primary products that the electrolytic nature of the decomposition need be considered; for the secondary reactions are merely those of ordinary chemistry.

The most generally accepted theory with regard to the nature of electrolytes is that which is known as the «ionic theory,» and which teaches that a salt whose solution is capable of electrolysis becomes more or less completely dissociated when it is dissolved, the respective parts into which its molecules subdivide being known as «ions.» This aspect of the phenomena of solution is considered in the article SOLUTION (q.v.), and in the present place we need dwell only on those features of the ionic theory which have an immediate bearing on the subject of electrolysis. The ions into which the electrolyte is resolved, upon solution, are supposed to be associated with definite charges of electricity, which cling to the ions so long as the dissociation persists, and can only be neutralized by causing the ions to come together again so as to re-form a molecule of the original salt, or to enter into other chemical combinations with one another; neutralization being effected, in such cases, by the actual discharge of the equal and opposite electricities into one another, as the re-combining ions come together. What the ions are, into which a given salt dissociates when it is dissolved, can only be discovered by inference from certain kinds of experiments for which reference must be made to the books cited in the article SOLUTION. Our knowledge on this point is still far from complete, but we know what the ions are in most of the simpler electrolytes. When potassium hydroxid, KOH, is dissolved in water, it becomes dissociated, or «ionized,» into the ions K and OH. At first thought it appears to be impossible to admit that potassium, which has so great an affinity for water, can exist in the free state in a solution; but it must be remembered that the potassium «ion» differs from the ordinary potassium atom by the possession of a definite and considerable electric charge, which modifies its chemical behavior profoundly. As the solution is concentrated by evaporation, the potassium ions and the hydroxyl ions (OH) come together, discharge into each other, and unite to form potassium hydroxid, KOH, which is deposited in the solid form. (Some of the hydroxid remains in solution as such, the dissociation never being complete except in exceedingly dilute solutions; but this point is not essential to our present purpose, and for its further elucidation reference must be made to the article SOLUTION.) In the ionized state, the potassium is charged positively and the hydroxyl negatively; and, in general, any ion which appears at the cathode during electrolysis is charged positively in the free solution, and any ion which appears at the anode is charged negatively. Moreover, the phenomena of electrolysis prove that any given ion is always associated with the same identical charge of electricity, no matter what the salt may have been from which the ion was obtained, provided the ion has the same valency in each of the salts that are compared. The potassium ion in a solution of potassium chlorid, for example, carries precisely the same charge as the potassium ion in a solution of potassium nitrate, or of potassium carbonate. We may therefore regard the free ions in a solution as so many little buckets filled with electricity, all the buckets having identically the same capacity.

According to this view, the ions act as mere carriers of electricity, and electrolysis is not simply an accompaniment of conduction through an electrolyte, but the very means by which this conduction is effected. The electric circuit in which the electrolysis occurs may be likened to a brook. If the metallic circuit is interrupted by the insertion of a solution of some kind, the solution so inserted corresponds to a dam in the brook, through which no water can pass by direct flow. The analogy is fairly complete when the solution does not contain free ions, for then it will not act as an electrolyte, and no current can pass. Sugar, for example, does not dissociate to any appreciable extent when it is dissolved, and hence a solution which contains nothing but pure water and pure sugar cannot conduct electricity, and merely acts as an impassable barrier to the current. When the solution contains a salt (such as sodium chlorid) which is largely or wholly dissociated, the free ions act like a molecular bucket brigade, passing the water across the dam in the brook, or the electricity across the gap between the two electrodes in the electrolytic cell. In the electrolysis of copper sulphate, for example, the phenomena are as follows: The formula of the sulphate is $CuSO_4$, and the free ions in the solution (and hence also the primary results of the decomposition) are copper and «sulphion,» SO_4; the copper ion being charged positively, and the sulphion ion negatively. The electrodes that are immersed in the electrolytic cell are also kept continuously charged by the battery (or dynamo) with which they are connected; the cathode being negative and the anode positive. The positively charged copper ions in the solution are therefore attracted by the negatively charged cathode, just as a positively charged pith ball is attracted by a negatively charged body in the air. Hence they move towards the cathode, and when they reach it they discharge their electricity upon it, thereby ceasing to be ions, and becoming transformed into atoms of ordinary copper, which are perforce deposited upon the cathode. The sulphion ions simultaneously move toward the anode, upon which they discharge the negative electricity that they carry. The ionic charge is essential to the continued existence of the sulphion, however, and when this charge is lost, the sulphion must either break up into sulphur dioxid and free oxygen, or else combine with some other substance to form a new compound. If the anode is made of platinum or carbon, the sulphion usually combines with a molecule of water with the liberation of free oxygen, as already explained in connection with the electrolysis of dilute sulphuric acid; but if the anode is made of a material that is less resistant to chemical action, the sulphion may combine with the anode itself instead of with a molecule of water. For example, when the anode is of copper, the sulphion, at the moment that it loses its electric charge, combines with an atom of the anode so as to form a molecule of copper sulphate.

The solvent, according to this theory, is to be regarded as an insulator, through which the electricity is passed by the ionic bucket-brigade. There is no real «conduction» through an electrolyte; but the positive charges that the ions bring to the cathode diminish the charge of the cathode so that more negative electricity must flow to it from the battery (or the dynamo), in order to maintain its potential; and, similarly, the negative charges that the ions carry to the anode require a constant supply of positive electricity from the battery, in order that the potential of the anode may be maintained. The general effect upon the circuit, therefore, is the same as though there were an actual conduction of electricity through the electrolyte. (For a further elaboration of the ionic theory of electrolysis, consult Whetham, 'Solution and Electrolysis.' See also SOLUTION.

By a detailed study of the secondary chemical actions that occur when salt solutions are electrolyzed, it has been found to be possible to isolate many of the metallic elements by electrolysis, when they are present in a mixed solution; and a promising system of «electro-chemical analysis» has been based upon this fact. Copper may be separated from cadmium, for example, by electrolyzing a solution of their mixed salts, in which free nitric acid is present, the copper being obtained in the metallic form, while the cadmium remains in solution. If the same solution is neutralized by potassium hydroxid, and then electrolyzed after the addition of potassium cyanide, the cadmium is deposited, while the copper remains in solution. The successful application of the principles of electrolysis to analysis requires an extensive knowledge of the secondary reactions that occur at the electrodes, however, as well as a full understanding of various practical conditions that must be carefully attended to. For these consult: Smith, 'Electro-Chemical Analysis' (1903), together with the references therein given. See ELECTRIC FURNACES: ELECTRO-CHEMICAL INDUSTRIES; ELECTRO-CHEMISTRY; ELECTRON; SOLUTION.

Electrolysis of Gas and Water Mains. In the system of street railway traction in which an overhead trolley wire is employed, with direct current, in which the tracks are utilized as a return circuit for the current to the power house, it has been found that damage has almost invariably ensued to the gas and water mains adjacent to the tracks, from electrolysis. This is due primarily to the electric current leaving the tracks and following the gas or water mains for some distance. At the points where the current leaves these pipes to return to the tracks or to the power house, if the soil is damp and contains soluble chlorides of magnesium, sodium or potassium, the current sets free acids or chlorine which attack the iron of the pipes; the rapidity and extent of the damage done thereby being proportional to the strength of the current, the duration of its application, and the constituents of the soil. The electrolytic action results in «pitting» the pipes, and bursting of water pipes and leakage of gas pipes is not uncommon from this cause. See illustration. Experiments have shown that with as low

Electrolytically Pitted Water Pipe.

a potential as .5 volt and a current of .03 ampere, noticeable electrolysis of an iron pipe has occurred in sand moistened with sea water. A current of 5 amperes acting for one year on an iron pipe would result in serious damage. Pipes on which the difference of potential was founds to be about 6 volts have burst in a few years. To prevent electrolysis due to this cause greater precautions are now taken, and with considerable success, to preserve the continuity of the rails by bonding, welding them *in situ* by electricity, by providing separate metallic return circuits and by connecting the water and gas mains by means of heavy copper wire at places where the current would otherwise return to the tracks via the earth.

Electrolyte, a compound which is decomposable, or is subjected to decomposition, by an electric current. See ELECTRIC STORAGE BATTERY.

Electro-magnetic Induction. See INDUCTION.

Electro-magnets. *Electro-magnetism.* The fact that when a current of electricity flows in a coil of insulated wire surrounding a bar or rod of soft iron, the iron becomes a magnet, was discovered in 1825 by William Sturgeon of England. He also discovered and pointed out in a paper read by him before the Society of Arts in that year, that the polarity of the magnet depended upon the direction of the current around the iron bar, and that it ceased to be a magnet when the current ceased to flow in the circuit. His two first electro-magnets were made in the shape of a horseshoe and a straight bar. The former was made of a bent rod of iron one foot in length and half an inch thick, around which a bare copper wire was wound 18 times, the iron having been previously covered with varnish to insulate the wire from the iron. The current was supplied by one large primary cell. This magnet was able to sustain a weight of nine pounds, though weighing itself only seven ounces. Subsequently Sturgeon constructed a horseshoe electromagnet 18 inches in length, 2¾ inches thick, and wound with 980 feet of copper wire one twelfth of an inch in diameter, which upheld 1,386 pounds.

The phenomena of electro-magnetism may be briefly described as follows. It is known that when iron filings are strewn over a cardboard or glass, if a bar or horseshoe magnet be placed under the cardboard the filings will tend to arrange themselves symmetrically when the cardboard is tapped. This it is assumed is due to the existence of so-called magnetic lines of force which are assumed to flow from the north to the south pole of the magnet, and the iron filings, becoming magnetized by these magnetic lines of force, tend to set themselves parallel thereto. Similarly, when an electric current flows in a wire (electro) magnetic lines of force surround the wire in circles or hoops which increase in density with the strength of the current. It is known that iron is a much better conductor of magnetic lines of force (or magnetism) than air, in the ratio of 1 to 100 or 150, depending on the quality or "permeability" of the iron. Hence when the wire is made in the form of a coil into which is inserted a soft iron bar, the magnetic lines of force, so to speak, use the iron as a circuit and the latter becomes a magnet having north and south poles.

The space between the poles of a magnet or wherever its magnetic lines of force extend, or in the space around a wire conveying a current of electricity, is termed a magnetic "field." The substances through which the lines of force pass, including the iron of the magnet, constitute the magnetic circuit. The expression *number of lines of force per square centimetre* in the material, is at present used as a measure of magnetic density. The total number of lines of force in a magnetic circuit is termed the *magnetic flux*, and is obtained by multiplying the total cross sectional area of the field in square centimetres by the density of a square centimetre of the circuit. The *magneto-motive force* (that is, the force that, as it were, drives the lines of force through the circuit) is equal to the product of the strength of current in amperes in the coil by the number of convolutions of the coil. This is also termed the *ampere turns*. The magnetic flux may be increased by increasing the magneto-motive force or by decreasing the resistance (termed the *reluctance*) of the magnetic circuit. Hence the relation between the foregoing terms to one another is analogous to electro-motive force, resistance and current, in an electrical circuit, and may be expressed by the equation:

$$\text{Magnetic flux} = \frac{\text{Magneto-motive force}}{\text{Reluctance.}}$$

It is to be noted, however, that the reluctance of a magnetic circuit containing iron is not a constant, but increases, in other words, its permeability to magnetization decreases, after a certain degree of magnetization, which is termed *saturation*, has been reached.

Electro-magnets are extensively used in telegraph and telephone apparatus, in dynamo machines, electric motors (q.v.), and for many other purposes. See UNITS.

Electrometer, an instrument for measuring differences of electric potential between two conductors through effects of electrostatic force, and not through certain electro-magnetic effects of electric currents produced by them. See ELECTRIC BALANCE.

Electro-motive force, a term used in connection with batteries and other sources of electric supply to denote the differences of potential existing between the plates or terminals, in consequence of which there is a tendency for a current to flow when the plates are connected by a conductor. See BATTERY; PRIMARY BATTERIES.

Electro-motograph, a name given to a peculiar telephone receiver invented by Edison, and constructed virtually as follows. A short metal strip, fastened at one end to the centre of a mica diaphragm, rests on a rotating cylinder, the surface of which is composed of moist gypsum impregnated with mercuric acetate and potash. The strip and cylinder are placed in series in a telephone circuit. When variations in current pass through the gypsum surface it is found that the friction between the strip and the cylinder varies directly with the current. When the current is weak the strip is drawn along in the direction of the cylinder's rotation against the natural tension of the mica diaphragm. When the current increases, the strip slips back in response to the pull of the diaphragm, and in this way the diaphragm is set into vibrations corresponding to those set up by the telephone transmitter. An explanation of this phenomena is that the current electrolytically sets free a thin layer of gas between the cylinder and strip, reducing the natural friction.

Elec'tron, one of the ultimate particles of which (according to the views now tentatively held by physicists) the atoms of matter are composed. The "electron hypothesis" is still in its infancy, and years will probably elapse before its truth or falsity can be demonstrated with any degree of certainty. It teaches that the atoms, which were formerly supposed to be simple bodies that are incapable of subdivision, or bodies which at all events do not undergo division in the ordinary processes of nature, are really systems of some considerable complexity, built up of thousands of still tinier "electrons," each of which is endowed with a permanent electric charge. The definite development of the electron hypothesis originated with the study of electric discharges through highly rarefied gases. Crookes, for example, boldly took the position that the luminous streams ("cathode rays") that proceed from the cathodes of highly exhausted vacuum tubes are composed of tiny material particles that are moving away from the cathodes like storms of projectiles. In support of this view he exhibited many ingenious and beautiful experiments, in which the corpuscular torrents were caused to turn paddlewheels and heat targets to whiteness within a vacuum. He did not definitely commit himself to any theory as to the precise nature of the corpuscles, but he recognized them as being somehow different from the ordinary molecules of matter, and he consistently and persistently maintained that the matter in these tubes is in a "fourth state," which is essentially different from the familiar gaseous, liquid and solid states, which matter has long been known to be capable of assuming. This fourth state he called "radiant matter." His views were opposed by many competent authorities, who adhered to the view that the cathode rays are wave-like phenomena, due in all probability to the extraordinary electrical stresses that are set up in the luminiferous ether within the tube, by the induction coil that is used to produce the discharge. As further experimental evidence has accumulated, however, the substantial correctness of Crookes' views has become increasingly evident, and the corpuscular nature of the cathode rays is now generally admitted. Numerous experiments have been made to prove that these corpuscles (electrons) carry electrical charges, and for determining the mass of the electrons and the magnitude of the electrical charges they carry. Let m be the mass of the electron, v the velocity with which it moves in the cathode stream, and e the electric charge associated with it. It can be shown that a magnetic field acting at right angles to the direction of the stream will cause the electron to describe a curved path instead of its normal straight one. If the magnetic force thus acting at right angles to the direction of the stream be a circle of radius $\frac{mv}{eH}$. By observing the actual curvature of the cathode stream under the influence of a known magetizing force H, we can therefore find the value of the expression $\frac{mv}{e}$. It is also known that the tendency of the magnetic force to produce curvature of the path of the electron can be neutralized by so arranging the experiment that the cathode stream is simultaneously exposed to a static electrical force of a particular intensity F, and acting in a direction that is perpendicular both to the cathode stream and to the magnetic force; the intensity, F, of the static force being such that the relation $Fe = Hev$ is fulfilled. By experiment, it is possible to find the numerical value of F by varying the electric force acting across the cathode stream until, under the combined influence of the static and magnetic forces, it is seen that the cathode stream is perfectly straight. When this condition is fulfilled, the equation just given shows that the velocity of the electron can be found by merely dividing the observed value of F by the observed value of H. The results obtained in this way indicate that the velocity of the electrons in the cathode stream is pretty much the same, whether the tube contains air, hydrogen, or carbon dioxid; it being about 2,500,000,000 centimetres per second (that is, about 15,000 miles), or something like one twelfth the velocity of light. The value of v being known, and the ration of mv to e being also known by a previous experiment in which the static field is omitted and the magnetic force allowed to act alone, we are at once in position to calculate the value of $\frac{e}{m}$ or the charge that is carried by the electron, per unit of its mass. The numerical result so obtained (and which is sensibly the same for all gases) is that each gram of the electron's mass, in the cathode stream, carries a charge of about 10^8 coulombs. Now in electrolysis (q.v.) the ions of hydrogen carry a charge of about 96,000 coulombs per gram of their mass; or, in round numbers, 10^5 coulombs per gram. Hence if the electrons in the cathode stream have a mass equal to that of the hydrogen ion in electrolysis, they must carry an electric charge that is 1,000 times as great as that carried by the hydrogen ion; and conversely, if (as many authorities consider probable) they carry the same electric charge as the hydrogen ions carry in electrolysis, it follows that the electron has a mass only about one one-thousandth as great as that of the hydrogen ion (or atom). The reasoning given above appears to be beyond reproach, and it is substantiated by other methods of experiment that cannot be here considered. J. J. Thomson, who has been especially prominent in connection with the development of the electron hypothesis, endeavored to determine which of the alternatives suggested above corresponds with the real facts of the case. His method for doing so is described in full detail in the 'Philosophical Magazine' for December 1898, but is too technical to be given in the present article. His general conclusion is, that the charge is the same upon the electron as it is upon the hydrogen ion in ordinary electrolysis; and hence that the mass of the hydrogen atom is 1,000 times as great as the mass of an electron. It is not certain that this conclusion will be fully sustained by future investigations, because some of the assumptions and observations upon which it is based have not yet been established beyond controversy. It may yet be found that the electron and the hydrogen atoms are not greatly different in mass, but that the electron carries a far larger charge of electricity than the ion that is concerned with electrolysis. Assuming the correctness of Thomson's views, certain physicists have elaborated fascinating hypotheses as to the constitution of matter, and have even attempted to explain the genesis of the definite species of matter that we call elements. (See ELEMENT.) It is not at all improbable that matter really is of only one fundamental kind, and that we shall one day know how the elements differ from one another. It is even possible that the electron hypothesis is the key that is to unlock this secret; but the subject is still too new for any definite and valuable judgment to be passed upon this phase of it. In general, there is a tendency towards the belief that the electrons are the fundamental units of which the atoms are composed; and according to this view they may be likened to the bricks with which buildings are constructed in human architecture. The electrons of all bodies are supposed to be identical with one another, and the atoms of any two elements, such as hydrogen and iron, for example, are supposed to differ only in the number of the electrons that they contain, and in the way in which these electrons are grouped. It is known that a swiftly-moving charge of electricity would show inertia-like effects, even if it were not associated, in its motion, with any body possessing true mass. Hence it has been thought probable, by many authorities, that the inertia of matter is capable of explanation in this way, if it is admitted that atoms are really composed of electrons flying around in orbits, about a mean configuration that is essentially stable so long as it is not subjected to external disturbances of too great a magnitude. These speculations, and others of the same sort, are given in Sir Oliver Lodge's interesting lecture "On Electrons," as published in the 'Scientific American Supplement,' beginning with the issue for 16 May 1903 (No. 1428). It is probable that the views now held upon these and other allied subjects will soon undergo a substantial modification of some sort, for it is next to impossible for the human mind to conceive of any such thing as a disembodied electric charge moving about in an orbit; and while such a description of the ultimate nature of the electron may serve well enough as a starting point upon which to base mathematical equations that shall explain the phenomena that we can observe and measure in the laboratory, it can never satisfy the craving of the physicist for a definite mental image of what is really going on in the atom. Whether such a mental image is possible or not, or whether or not it is logical to strive for its attainment, are fair questions for discussion; but it is certain that the general trend of physics has been in this direction in the past, and there is no reason to suppose that the same tendency will not be equally manifest in the future. Electroplating. Given a solution of the salts of a metal, say, for instance, sulphate of copper (the constituents of which are sulphuric acid and copper oxide), in which are immersed a copper plate connected with the positive pole of a source of electro-motive force, and a metal plate connected with the negative pole; when an electric current is passed through the solution an action takes place which may be described as follows: First, the salt is decomposed into sulphuric acid and oxide of copper. At the same time a portion of the water of the solution is also decomposed, setting free hydrogen and oxygen. The oxygen of the oxide of copper is drawn to the negative pole, where it unites with a portion of the hydrogen just freed, forming water, and the metallic copper thus set free is deposited uniformly on the negative metal plate. Simultaneously with this action sulphuric acid and oxygen arrive at the positive plate, where the oxygen unites with a particle of the copper plate, forming oxide of copper, with which the sulphuric combines, forming sulphate of copper; which process is continued as long as there is any metal left in the positive plate. For each atom of copper thus dissolved at the positive plate another is set free at the negative plate. Actions analogous to these underlie all electroplating and electrotyping operations. If it is desired to deposit nickel, silver, gold, or other metal on the object, salts of those metals instead of copper will be used in the solution or *bath,* as it is termed.

The art of electroplating and electrotyping (q.v.) is now extensively practised. The current for the decomposition of the electrolyte, or solution, is usually supplied by continuous-current dynamo machines which are designed to give large currents at electro-motive forces, rarely exceeding three to five volts. Sufficient electro-motive force must be provided to decompose the solution, but the amount of chemical decomposition depends altogether on and is proportional to the strength of the current. If too high electro-motive force or too large currents are used, the plating is uneven and granular. Storage or primary batteries may also be used for this purpose, and are so used for plating on a small scale. Much care and special knowledge is required to obtain the best results in electroplating. The process is begun by thoroughly scouring the article to be plated to remove all trace of oxide or other impurity from its surface. In the case, for instance, of gold, silver, or nickel plating, the bath or solution employed by some electroplaters consists of 100 parts water, 10 of cyanide of potassium, and 1 of the cyanide of gold, silver, or nickel, as the case may be. Plates of either of these metals are suspended in the bath as the positive pole, while the article to be plated is suspended in the bath as the negative pole. When the plating has proceeded to the desired depth or thickness the articles are taken out and burnished. Such parts of the article as it may not be desired to plate are covered with grease, oil, or wax. When non-metallic articles are to be plated they are first given a coating of wax, over which is laid a film of powdered plumbago, upon which the plating then takes place. See 'Brunor's Electroplater,' a text-book on the subject.

Electropoion, a mixture of sulphuric acid, bichromate of potash, and water used as the liquid for batteries in which zinc and carbon are the poles. See BATTERY.

Electropyrometer. See PYROMETER.

Electroscope. This is an instrument used to indicate the presence of electricity in a substance, and may be used to show whether the electricity is negative or positive. In one form it consists of a wide-mouthed vial stoppered with a cork, through the centre of which a metal rod passes into the middle of the vial. There is a brass knob at the top of this rod, and its lower end is bent or hooked to support a narrow strip of gold foil, which is folded in equal lengths over the hook. When a rubbed glass rod is brought near the brass knob, positive electricity is attracted and negative electricity is repelled to the gold leaves, which diverge by reason of the repulsion of the similar electricity on the leaves. To show the kind of electricity with which the leaves are charged, or with which another body may be charged, a finger is placed on the brass knob while yet the glass rod is near it. This allows the negative electricity to escape. When next the finger and then the rod are removed, the positive electricity is dispersed over the gold leaf system and the leaves again diverge. If now, while the leaves are charged with positive electricity, a positively charged rod be brought near the knob, the leaves tend to diverge still farther. If a negatively charged rod is used, the positive electricity in the leaves is attracted and the leaves tend to collapse.

Electroscopes of this general type are now utilized on account of their great susceptibility to the presence of electricity, to detect and measure the radioactivity of weakly radiating substances like uranium and thorium, advantage being taken of the ionizing properties of such substances by which the particles of gases become carriers of electric charges proportional to the radioactivity of the substances. For this purpose the gold leaf system is placed in metallic connection with the upper plate of a small air condenser, on the lower plate of which is spread a layer of the radioactive material. A source of electro-motive force is connected with the lower plate and the movement of the gold leaf is noted, the rate and extent of which, varying with the radioactivity of the substance, comparisons can be readily made of different substances connected with the lower plate, and the movement of the gold leaf is noted. As the rate and extent of this movement vary with the radioactivity of the substance, comparisons can be readily made of different substances or with a standard.

Electrostatics is the part of the science of electricity that treats of the phenomena of electricity at rest. See ELECTRICITY.

Electrotaxis. See ELECTROCULTURE OF PLANTS.

Electro-therapeutics. The treatment of disease by electricity dates back at least to the middle of the 18th century, about which time the electric spark and frictional electricity were employed for that purpose. In 1753 Franklin utilized shocks from Leyden jars (charged by electric machines) in the treatment of paralysis and other ailments. In 1775 the effects of the Franklinic current (high potential static electricity) upon the human system was in some respects almost as well known as it is to-day. Thus, in 1777 Tiberius Cavallo, the well-known philosopher and writer of that time, records, with respect to communicated electricity, that its application either as simple electrization or in the form of sparks and shocks to the human body has been unquestionably serviceable in various disorders, some of which have resisted every other medical application.

The discovery of voltaic or galvanic electricity (primary battery) in 1800, and of induced or faradic electricity (induction coil) about the middle of the last century opened up a new field as regards the use of electricity in the treatment of disease, by affording a more gentle treatment than the shocks and sparks from Leyden jars, and for long intervals static electricity was but little used. The improvements in apparatus and methods of application in later-day practice have however made it possible to use static electricity with little or no inconvenience to the patient.

The currents used in therapeutics are commonly known as the galvanic, faradic, and franklinic currents, named respectively after Galvani, Faraday, and Franklin. These terms refer to the prime source of the current. Thus the galvanic current is due to a primary or storage battery, the faradic current is derived from induction coils or from small magneto-electric machines with a rotating armature; the franklinic current is developed by static electric machines (influence or frictional).

In a proposed new nomenclature relating to electro-therapeutics it has been suggested to term these currents voltaic current, induced current, and static current, respectively. Currents induced by induction coils are frequently termed coil currents. In the new classification of currents, also, a direct current is a current in one direction only, which may at times have a zero value. A continuous current is also a direct current, one that may vary in strength, but does not reach a zero value. A constant current is one which does not vary in strength, (a constant current presupposes a constant electro-motive force and resistance in the circuit). A pulsating current is an interrupted direct current which varies from zero to maximum periodically. It may be set up by interrupting a direct current at regular intervals. The form of the pulsating current will vary with the nature of the circuit. The direct, the continuous, the constant, and the pulsating current may be supplied by a primary or storage battery, or a direct current dynamo machine; these currents may be either positive or negative in direction, uniformly.

An alternating current is one which rises from zero to, say, positive maximum, falls to positive zero, then passes to negative maximum and back to negative zero, in regular periods or cycles. When the positive and negative maximums are equal, and the rise and fall are uniform and gradual, the current may be represented by a sine curve, and is termed a sinusoidal current. Special machines are manufactured to generate sinusoidal currents for use in therapeutics. Alternating currents developed by induction coils are not of uniform positive and negative strength, and may be represented by an unsymmetrical curve or wave. Alternating currents are also obtained from alternating current dynamo machines or generators, including the specially made sinusoidal machines referred to, and from induction coils. See DYNAMO MACHINES; WIRELESS TELEGRAPHY.

An oscillating current is one which alternates in direction at a given rate or frequency, but whose amplitude of vibration falls in a given ratio. Oscillating currents are set up by Leyden jars or condensers in discharging. See WIRELESS TELEGRAPHY; OSCILLATING CURRENTS; also ELECTRIC STATIC MACHINE.

Direct Current in Therapeutics.—The direct current is used in therapeutics for its electrolytic and cataphoretic action on the constituents of the body.

As the human body is one which conducts electricity by virtue of its salts in solution (chiefly chloride of sodium, or common salt), it is virtually an electrolyte in its relation to an electric current; hence the passage of a direct current through the body causes a decomposition of the salts of the body, to which is primarily due many of the valuable therapeutic effects of the electric current.

Concurrently with electrolysis, phoresis also takes place in the electrolyte. In an electrolyte the second action of the current is to draw or move along with it the ions of the fluids in its path, which action is termed phoresis. When the ions move toward the cathode the effect is termed cataphoresis; when toward the anode, anaphoresis. Advantage is taken of this action, usually the cataphoric, to introduce into the body, through the skin or mucous membrane, by means of the direct current, certain drugs — iron, quinine, cocaine, morphine, etc.— in solution, to the parts to be acted on. This is termed cataphoric medication. By cataphoric action cocaine is successfully employed as a local anæsthetic in dentistry. By the use of heavy currents and amalgamated zinc needles cataphoresis is employed with success in the destruction of malignant tumors and to sterilize surrounding tissues.

The electrolytic effects of the direct current are at least of two kinds, termed polar and interpolar electrolysis. In the first, the effect is mainly at the electrodes (needles); the acids and alkalis set free by the current attacking and recombining with the molecules of the tissues, which, by this secondary chemical effect, assist in their own destruction, as in the case of tumors treated by this method. In interpolar electrolysis the effect is distributed over a larger area, the known beneficial results being presumably due to the reactions set up by the current, which reactions assist in the absorption of morbid tissues, thereby tending to increased nutrition and thus aiding in the formation of normal tissue.

The electrical resistance of the body may range from 500 ohms to 10,000 or more ohms, according to the nature of the contact at the electrodes. The current may be applied, percutaneously by means of electrodes moistened with water, to which a little bicarbonate of soda has been added to improve the conductivity; by electrodes applied to mucous membrane; or by the insertion of needle electrodes in the tissues. For percutaneous applications comparatively high voltages are necessary, 30 to 60 volts. The current strength used is small and is measured in milliamperes (thousandths of an ampere) by a milliammeter. The average percutaneous application is about 7 milliamperes for one square inch of electrode surface; about 15 milliamperes for two square inches. The amount of current employed must be varied according to the purpose for which it is employed; in some cases, as near the brain or eye, only a fraction of a milliampere, or two to three milliamperes at most, are required. Vertigo and flashes of light are produced and taste is excited by the passage of weak direct current through the brain from moistened electrodes. It is not advisable or safe to apply more than 100 milliamperes direct current through any vital part of the body, as from hand to hand. In gynæcological work, currents of 50 to 500 milliamperes are utilized, a large moistened electrode being applied externally while a small metallic electrode is employed internally. The direct current does not produce shocks except at the opening and closing of circuits. Some practitioners have obtained favorable results by the use of 40 to 100 milliamperes direct current passed through the body by means of large electrodes placed on the abdomen and lumbar regions to influence the abdominal viscera. Similar current strengths have also given favorable results in gastro-intestinal disorders, malnutrition, and neuralgia.

In Fig. 1 is illustrated a 30-cell voltaic battery of dry cells employed in direct current therapeutics. In the figure A is a milliammeter; C is a cell selector, by means of which the number of cells in use may be quickly regulated. The current flow may also be regulated by the rheostat R, consisting of carbon or fine coils of wire. P is a pole-reversing switch, by means of which the direction of the current in the external circuit may be reversed as desired. This battery will give an electro-motive force of about 45 volts. Batteries of the Grenet type (bichromate of potash) will give an electro-motive force of about 2 volts per cell, and 30 such cells may be used in the treatment of fibroid tumors, according to Apostoli's method.

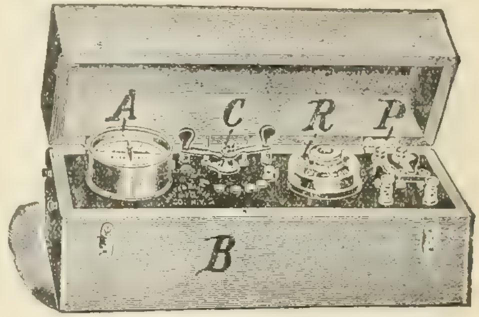

Fig. 1.—Voltaic Battery Apparatus.

Alternating Currents in Therapeutics.—For portable use the induction coil, or faradic apparatus, as it is commonly termed, is virtually the only present means of obtaining alternating currents, sinusoidal machines and static interrupters being by their weight limited to office use. A portable faradic apparatus is illustrated in Fig. 2, with induction coil I, vibrators V, elec-

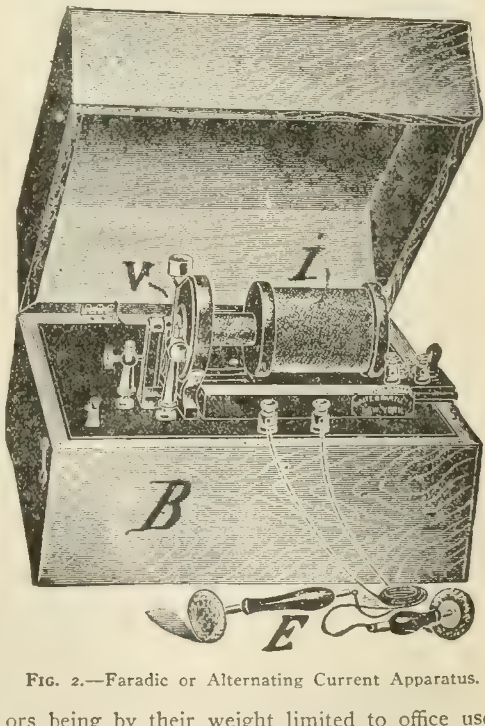

Fig. 2.—Faradic or Alternating Current Apparatus.

trodes E, etc. The battery, usually two large, dry, voltaic cells, are contained within the case B. In this apparatus the low voltage and comparatively high current of the primary circuit are transformed to a high voltage and low current in the secondary circuit. The rate of interruptions of the current is variable by means of quick (or fine) and slow vibrators, or interruptors, of the primary circuit. The vibrators for this work should operate uniformly steadily to avoid unpleasant jerks and shocks to the patient. A contact is also provided in the apparatus by means of which single impulses may be given. Other types of such apparatus are made with two or more secondary coils to give different values of potential and current. Slow vibrations include those from 50 to 150 per minute, at which rates the muscles contract and relax between each contraction; above 150 vibrations per minute the muscles remain contracted during the application of the alternating current. By means of quick vibrators 12,000 to 18,000 interruptions per minute are obtainable.

When the alternating currents are sinusoidal they do not produce permanent electrolysis, since the effect of a current in one direction is presumably at once neutralized by a current in the opposite direction. When the current of one polarity preponderates in strength or duration over the other current, electrolysis may ensue. In either case, however, there may be a tendency to decomposition or splitting of the molecules, which action accelerates or stimulates metabolism with beneficial results. The application of an alternating current or of an interrupted direct current for a short time (20 minutes daily), with intervals of rest, has by experiment been found to stimulate muscles and improve nutrition in a somewhat equal degree, primarily by electrolysis "and the subsequent dispersion of the products of the electrolytic decomposition by the shocks." The stimulating property of alternating currents is utilized in the treatment of diseases of the neuro-muscular system. The tetanizing, or sedative, effect of rapidly alternating coil currents on the striated and non-striated muscles has led to their use to allay pain in pelvic disorders. According to Morton, the sedative property of such currents is perhaps due to a mechanical action of the current upon the nerve filaments, producing a commotion resembling that accompanying cerebral concussion.

To obtain the sedative effect from this current, the fine vibrator of the apparatus (Fig. 2) is used; for tonic effects and massage the slow vibrator is employed.

Sinusoidal Current in Therapeutics.—As this is a symmetrical current, its positive and negative polarities are of equal strength and duration: hence it is not supposed to possess electrolytic or cataphoretic properties. Therefore certain of the beneficial results derived from the use of this current may be ascribed to the excitement of the normal functions to greater activity. An important characteristic of the sinusoidal current in therapeutics is its uniformly graduated rise and fall of current strength and potential, whereby the unpleasant effects of the shocks that frequently accompany the application of ordinary coil currents are largely avoided.

This current is also extensively employed for the alleviation of pain in cases of uterine inflammation, vaginal prolapsus, ovaritis, and other pelvic troubles. It is also used advantageously in local paralysis, and diminished intestinal peristalsis, when these ailments are due to vasomotor debility or lack of muscular tone.

In some types of sinusoidal machines, 10,000 alternations per second are obtainable with an electro-motive force that varies with the speed of rotation of the machine, from 30 to 100 volts.

Static Electricity in Therapeutics.—The use of high potential static electricity in therapeutics has had several waves of popularity during a period of 150 years. For years at a time it has enjoyed a vogue and then has fallen into comparative disuse. At the present time, and for the past quarter of a century, it has been on a rising wave, although even yet its curative and remedial properties are frequently questioned. It has been pointed out, however, by various writers that the doubters regarding the beneficial effects of static electricity in therapeutics are generally from the ranks of those who have had little or no experience with its effects, whilst its foremost advocates are among those who have had a large experience therewith.

High potential static electricity is produced for therapeutical purposes almost exclusively by electric static machines (q.v.). These machines give a very high electro-motive force (in the case of a machine giving a 12-inch spark, about 100,000 volts), but very low current, namely, less than 1 milliampere. It is to this fact that some authorities attribute the small degree of danger that accompanies the application of static currents, the diffusion of currents of such low strength producing mechanical effects with little or no electrolytic effects.

The current from a Holtz static machine is a continuous direct current, as much so as the current from a voltaic battery, when the machine is run at constant speed and when other conditions are stable. The current from these machines is applied to the patient in a number of ways, in several of which the current is supposed to be oscillatory or pulsatory, owing to the introduction of a Leyden jar in series or in shunt with the patient; or because of the fact that the patient and the surrounding objects provide capacity, which discharges as a more or less oscillatory current.

A modern static machine, together with a number of the electrodes employed in practice, are shown in Fig. 3. Machines of this type are made in sizes ranging from 8 stationary plates and 8 30-inch revolving plates, to 18 stationary and 18 revolving plates, 32 inches in diameter. The machine is driven by a small electric motor *m*. The exciter is a small Wimshurst machine *w*, rotated by means of the hand-operated pulley P. C C are the prime conductors; *n n* are sliding rods; J J are Leyden jars. Two additional pairs of smaller Leyden jars are shown on insulated stand S. The patient is usually placed on this stand, which is removed two to three feet from the machine. K is the concentrator used to concentrate the static current on any desired part of the patient's body, for which purpose it is connected by a chain or other metallic connection to one pole of the machine or to the ground. *A* is a wood-point electrode; *b* is a brass-point electrode; *c* is a brass brush; *d* is a chain holder; *e* is a carbon point; *f* is a massage roller; *g* are cords, handles, and sponges; *h* is a wood ball; *i* is a brass ball.

Different applications of static electricity are termed the breeze, the spray (or brush), the spark, general electrification, etc. The therapeutic applications of the direct and alternating current are of a local nature. Applications of static electricity are of the nature of a general electrification, even when applied locally, by reason of the electrified condition of the surrounding atmosphere when the static machine is in operation.

General electrification may be given by placing the patient on the insulated platform, which

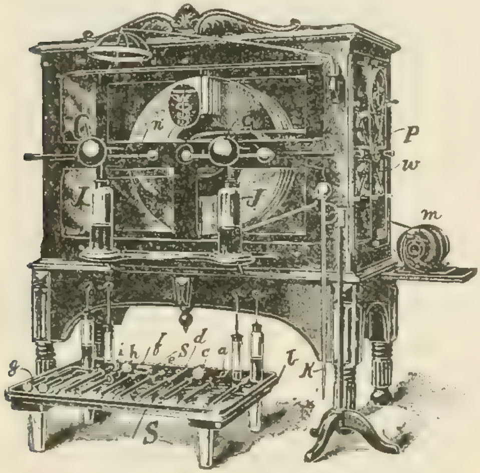

Fig. 3.—Modern Static Electric Machine.

is connected with one pole of the machine by means of a metallic rod, the other pole of the machine being grounded, and the sliding poles *n n* (Fig. 3) being widely separated. Or the patient may hold the chain connecting with one pole of the machine while the other pole is grounded. In this electrification (also termed the static bath) the Leyden jars are not employed.

To give the breeze application the patient is seated on the platform, to which one pole of the machine is connected by the metallic rod; the other pole of the machine being grounded by a chain touching the floor, or, preferably, connected to the water- or gas-pipe. On the approach of a pointed brass rod (concentrator) suitably connected to the grounded pole of the machine, an electric breeze of electrified air particles is set up. When the concentrator is brought still nearer to the patient a visible spray or breeze discharge passes from the metallic point to the body, but no sense of shock is perceived. By means of a metallic crown placed at a proper distance above the patient's head, an electric breeze streams to the body, causing the patient's hair to rise and imparting a feeling of well-being. This pleasant feeling, however, depends in some cases on the polarity of the electrification, and therefore that polarity which ensures best results should be selected. An extension of the breeze treatment consists in placing the patient within a metallic cage, by which a general breeze is diffused over the entire body.

To give the static spark, the concentrator is displaced by a brass ball electrode, which is approached toward a desired part of the patient's body, with a quick movement, to within the sparking distance of the current. The spark, properly applied, gives a not unpleasant shock and produces very strong and widespread muscular contraction. The spark treatment should, however, be used with great caution upon highly sensitive or nervous patients. Static massage is given by passing the electrode *f* (Fig. 3) over the parts which are to be treated. The electrode may be connected to the negative or positive pole, the patient being insulated from the opposite pole.

The arrangement of circuits to produce the greatest benefit and least discomfort to the patient has been a matter of much experiment. One of the approved methods is outlined in Fig. 4. It gives what is known as the Morton Static-Induced current of high frequency. Here the patient is in a shunt circuit with the spark gap of the prime conductors or electrodes and is protected by the spark gap s from unpleasant or dangerous shocks. c c are condensers of small capacity that tend to the setting up of rapidly oscillating currents, if the electrical resistance of the patient be small. For the production of the electric breeze, the spray or brush discharge the arrangement may also be as indicated in Fig. 5, in which a metal crown is connected with one prime conductor and is held over any desired portion of the body of the patient. In general it may be said that the currents from electric machines now most used in therapeutics are the brush, the spark, and the wave; the wave being applied by replacing the crown, Fig. 5, with a piece of metal foil, which is held against the patient's body; the other electrode resting on the insulated platform.

The strength and potential of current or

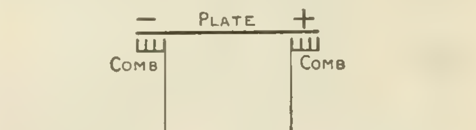

Fig. 4.—Static Induction, High Frequency Arrangement.

dosage with a given machine may be regulated, among other ways, by varying the rotation of the plates; also by varying the distance of the chain (that rests on the platform) from the feet of the patient, or by increasing the conductivity of the surface of the platform by resting the patient's feet on a metallic plate connected with the said chain. Where the patient is in shunt circuit with the condensers J J (Fig. 3), the dosage may be varied by adjusting the position of the rods $n\ n$ relatively to one another, the minimum effect being produced when the rods are together. See also Fig. 4.

As already remarked, high potential oscillatory currents are obtainable by means of condensers placed as shown in Fig. 4. To insure, however, that the currents shall be oscillatory it is necessary that R^2C must be less than 4L where R is resistance of the oscillating circuit in ohms, C its capacity in farads, and L its inductance in henrys. It has been thought by some practitioners for several years that the beneficial results obtained by means of static induced currents have been due to the assumed oscillatory character of the current; but, owing to the fact that the resistance of the circuit is frequently sufficient to make the current non-oscillating, and possibly a pulsatory current of very short duration, it has been suggested by Messrs. Jenks and Clarke that the salutary therapeutic effects obtained by means of the static machine currents in connection with condenser action may be due merely to the rapidly variable electric effects upon the human system, and not necessarily to an oscillatory character of the currents. For an elaboration of this question by the gentlemen named, the reader may be referred to 'Transactions of the International Electrical Congress, 1904,' p. 184, Vol. III.

Quite high frequency currents are also obtained by means of an induction coil arranged

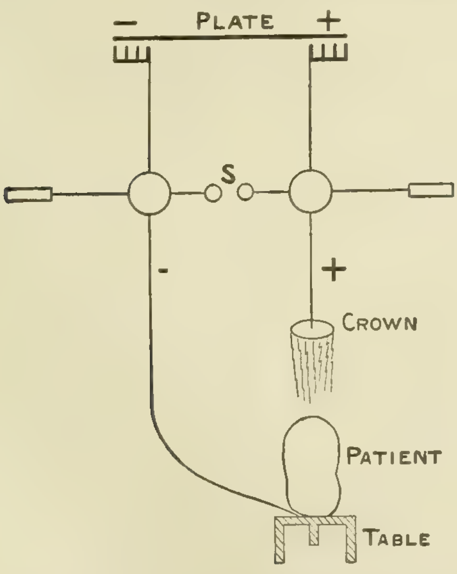

FIG. 5.—Arrangement for Breeze Discharge.

as outlined in Fig. 6, known as the D'Arsonval high frequency apparatus. The secondary terminals of the coil are connected to condensers C C as indicated. A coil of thick copper wire w, with a few turns, is connected to the outer castings of the condensers. One electrode is connected to one end of w; the other electrode may be connected to any desired turn of the wire by a sliding contact s, by means of which the current diverted to the patient P may be regulated at will. The effect may also be varied by adjusting the spark-gap G. According to D'Arsonval, a frequency of 1,000,000 per second is obtainable with this apparatus. This arrangement is somewhat like the Tesla high frequency device. A static machine may be used in place of the induction coil in Fig. 5.

The physiological effects of static electricity are many. The fact that the body loses weight while undergoing static electrification, and that an abnormal pulse or temperature are raised or lowered, as the case may be, was known over 100 years ago. Tests of the excretions of the body shows that this is due to increased functional activity. In the language of a committee of the American Electrotherapeutics, on 'Standard Electrostatic or Influence Machines,' "the physiological effects of static electricity are pretty much all that are produced by electricity; it sets free the potential energy of the cells of the human organism, it causes contraction of protoplasm, it excites nerve-fibres, nerve-cells, and nerve-centres, all of them are excited to functional action and caused to produce their separate effects — motor, sensory, special sense, secretory, sympathetic, vaso-motor, etc. It has a mechanical action. It disturbs the molecular arrangement of tissues and causes a new arrangement, resulting in modification of nutrition. It promotes nutrition of every part it excites; it produces marked local and general circulatory effects and stimulates the vaso-motor system.

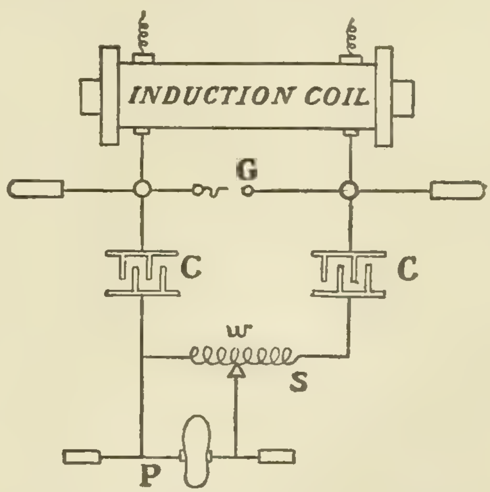

FIG. 6.—D'Arsonval High Frequency Apparatus.

It promotes metabolism and tissue metamorphoses, creates a feeling of refreshment to the system, and causes the reabsorption of exudative material of a chronic nature, and has a revulsive action of the skin."

Static electricity has been found effective in the treatment of lumbago, spastic paralysis, locomotor ataxia, chronic and muscular rheumatism, neuritis, progressive muscular atrophy, insomnia, congestion of the liver, and sciaticas. It controls nervous headaches, hysteria, neurasthenia, and is an excellent general tonic. It has been found especially beneficial in the prompt reduction of sprains, the application of the wave current by means of a metallic foil electrode over or around the part effecting remarkable curative results, presumably by a massage or mechanical effect. The effective use of the spark from this machine to ionize the air to produce nitrous oxide for the treatment of external ulcers may also be noted. Neither static electricity, however, nor electricity in any of its forms, is a panacea for every ill — such a claim may be left to charlatans — but their remedial effects are now too well established to leave any question as to their great therapeutic value in the hands of intelligent and skilful therapeutists. The importance of a high degree of skill and intelligence on the part of the operator in the use of these modalities cannot, however, be too strongly emphasized. The possible ill effect, for instance, upon a certain class of patients of increased blood pressure, which, it is well established, occurs under static electrification, is perhaps alone sufficient to warrant this caution and to make it apparent that a thorough course in the use of the apparatus employed in electro-therapeutics, and of the effect of electricity upon the human system in health and disease, should be regarded as essential on the part of every physician prior to undertaking the employment of this remedial and curative agent in his practice. If the skill and knowledge just indicated may properly be regarded as requisite on the part of the trained physician, it is obviously very questionable whether the application of electricity therapeutically should be allowed indiscriminately in the hands of laymen. Indeed certain writers of authority on this subject insist that, in view of the foregoing considerations, none but regularly graduated physicians should be permitted to apply electricity therapeutically.

The applications of electricity in therapeutics are much too numerous to discuss fully in a brief article; in the foregoing only a mere outline of them has been attempted. The use of electricity as a source of heat in electric cautery and as a source of light for illuminating the human body is not touched upon herein; its use in X-ray work is referred to elsewhere.

William Maver, Jr.

Electrotint, a method of tracing drawings, etc., for printing by the action of electricity on a copper plate. The design is drawn in some varnish not affected by acid and placed in an electro-bath, the lines being thus brought out in relief.

Electrotrophism. See Electroculture of Plants.

Electrotype, a copy of a form of type, made by means of electricity. A page of the type is covered with wax, which is driven into the interstices by powerful pressure. The face of the wax mold is covered with plumbago to give it a conducting surface to which the metal will adhere. The negative pole of a battery is attached to the mold, and the positive to a copper plate, and both are placed in a bath of sulphate of copper in solution. The copper is deposited on the face of the mold in a thin film, which increases in thickness as the process continues. The shell having attained the thickness of a stout sheet of paper, the mold is removed from the bath, the shell detached and strengthened by a backing of type-metal. The back of the shell is first coated with tin, and the shell is then placed face downward on a plate, and over a bath of molten type-metal. When it has attained the requisite heat, a quantity of the metal is dipped up and floated over the back of the shell. When cold, the plate is reduced to an even thickness by a planing-machine. For printing, it is mounted on a wooden backing. Another mode of obtaining electrotype plates from a letter-press form is by a mold of gutta-percha, brushed with graphite and immersed in the electro-plating bath. Gutta-percha is also used for obtaining intaglio molds and then cameo impressions from woodcuts, for printing. See also Electro-chemistry, Industrial; Photo-Engraving; Printing.

Elec'trum, a substance mentioned by Greek and Latin writers, with regard to the nature of which there has been much discussion. The term was used with different meanings; it originally meant gold, and was then applied specially to native gold, containing quantities of silver, copper, and other metals. The term employed for this native alloy was transferred to the artificial alloy of gold and silver, afterward made, and was also applied to amber on account of its color and inferior lustre.

Elegy, properly, a poem of mourning. The Greeks and Romans, however, employed the term to denote a poem written in elegiac verse, whatever its character. This elegiac verse was the distich, consisting of the hexameter alternating with pentameter. In modern times the term elegy is usually applied to any serious piece in which a tone of melancholy pervades the sentiments, as in Gray's 'Elegy Written in a Country Churchyard.'

Elegy Written in a Country Churchyard, a poem by Thomas Gray, and published in 1751. Its sincerity and simplicity of thought and language made it immediately popular, and it rapidly passed through a number of editions, and has since been often reprinted. It is thought that the churchyard is that of the parish church at Stoke Pogis.

El'ement, in chemistry, a substance that cannot be decomposed into other substances. Something like 77 different substances are now admitted by chemists to be elements, and a number of others are tentatively assumed to be so, until further evidence, for or against their elemental character, is accumulated. (A list of those that are now admitted is given under Atomic Theory.) Much speculation has been indulged in, concerning the fundamental structural differences that subsist between the atoms of the different elements, but no universally acceptable explanation has yet been offered to account for the fact that the thousands of compounds that have been studied are all composed of so small a number of essentially different constituents. The alchemists believed that every apparent "element" can be modified, or "transmuted," into every other one, and much labor was expended in the effort to transmute the baser metals into the "nobler," or more valuable ones. We now know that the problem of transmutation, if it is capable of solution at all, is at any rate far more serious than it was believed to be in the early history of chemistry. But there are numerous indications which suggest a relationship among the substances that are now accepted as elements, and it may yet prove to be possible to transform lead into gold, or tin into platinum. For some years past Sir William Crookes has been a consistent advocate of the theory which teaches that all matter is fundamentally the same, and he has shown that some of the "elements" can be resolved, by fractionation, into substances which exhibit spectra that differ from one another in a marked manner, any two consecutive members of the series showing close similarity in their spectra, while the extreme members of the series are totally dissimilar. (See his lecture before the Berlin Congress of Applied Chemistry, entitled 'Modern Views on Matter,' in 'Science' for 26 June 1903.) The theory of matter which is in favor at the present writing teaches that all atoms are composed of electrons (q.v.), which are all alike, but which are grouped together in various ways, and in various numbers, to form the atoms of the elements. If this view stands the test of further research, the possibility of transmuting the elements into one another may not be altogether fanciful. The newly discovered element radium (q.v.), which appears to possess the singular power of continuously emitting streams of free electrons, occurs in nature in certain varieties of the mineral uraninite. It is notable that the inert gas helium (q.v.) also occurs in this same mineral, though it appears to be present in the free state, and never in actual chemical combination. It has been suggested that we are here face to face with a real case of transmutation of elements, the electrons that are emitted by the radium being slowly built up, within the uraninite, into new systems, which are nothing less than atoms of helium. See MOLECULAR THEORY; PERIODIC LAW; RADIATION; RADIUM.

Elemental Spirits, beings who, according to the popular belief of the Middle Ages, presided over the four elements, living in and ruling them. The elemental spirits of fire were called salamanders; those of water, undines; those of the air, sylphs; and those of the earth, gnomes. Paracelsus wrote a treatise upon them, and they play a part in Pope's 'The Rape of the Lock.'

El'emi, a name given to fragrant resinous extracts obtained chiefly from trees of the order *Burseraceæ.* The hard elemi, most abundant in the West Indies, is obtained from species of *Bursera,* and is either yellowish or greenish, sometimes opaque and sometimes translucent, has a fatty lustre, is easily pulverized, and very fusible. It is heavier than water, in which it is insoluble, although it is readily dissolved in either turpentine or alcohol. African elemi is an extract of *Boswellia freereana* or *Santiriopsis balsamifera;* Manila elemi a product of *Canarium commune;* and the Mauritius variety is obtained from *Canarium paniculatum.* A large part of the elemi of commerce is produced from trees of different genera of the same family growing in tropical America. Elemi is a regular constituent of spirit varnishes, and the Manila kind is used in plasters and ointments. In Eastern countries it is also used as incense. Its active principle is a volatile oil obtained by distillation.

Elephant, the largest of living land animals, the two species of which constitute the family *Elephantidæ,* of the sub-order *Proboscidea.* The better-known species (*Elephas asiaticus*) is native to the jungles of India; while the other species (*E. africanus*) is found in the forests of Africa.

The elephant is a huge ungainly creature with an enormously heavy body, mounted on four short, columnar legs, the hinder ones bending like knees when he lies down, as he doubles them behind, and not under him; his tail is long and tapered, ending in a bunch of coarse hair; otherwise the wrinkled bluish-gray hide is quite hairless. His head is large, with big pendulous ears, small eyes, and a nose, prolonged into a proboscis or "trunk," which reaches quite to the ground when he stands erect. The average male elephant is 8 or 10 feet high, and weighs 5 tons or more. The incisors of his upper jaw are prolonged into tusks, which are, however, less useful to him, as weapons, than is his trunk. This organ enables the animal to pick up things from the ground, and to reach fruits or leaves many feet above his head, and it also conveys water to the mouth. Indeed, so great is the tactile sense of this singularly flexible proboscis that it has been likened to a hand. It is also its owner's chief weapon of offense and defense; for with it he can catch and crush a man with ease, or hurl aside the tiger. The age which this huge creature attains is proportionate to its size; for captive specimens have been known to live a hundred years, and scientists believe that, in a wild state, it may live many years longer.

The Indian elephant (*Elephas asiaticus*) differs from the African in having a longer head with concave forehead and smaller eyes and ears; in this species, also, the hind feet are often five-toed, whereas in the African they are never more than four-toed. Though the two species present some differences as to dentition, the special peculiarity in the structure of the molars is common to both. These teeth are of great size, and are formed of vertical plates of dental bone, separately covered with enamel, and welded together by a bony "cement," so that each tooth looks like a number of teeth, cemented together. In both species, also, there are no canine teeth, and no incisors in the lower jaw; while the incisors of the upper jaw are developed into tusks, often weighing 150 to 200 pounds each. These tusks furnish the ivory (q.v.) which is so much esteemed for ornamental purposes.

The Indian elephant has been for thousands of years the servant of man. From the earliest ages he has borne the Oriental warrior into battle, has hauled his stores and ammunition, and has even been taught to wield weapons. In peace he has piled logs and huge blocks of stone as unremittingly as a derrick, and has been the main feature in the processions of the native princes. In these last and always spectacular functions, the elephant's anklets, saddlecloth, and trappings are often encrusted with gold and jewels; and the prince who sits in the canopied howdah on his back, is not more gorgeously attired than his elephant. In this connection, also, the albinos of the elephant are prized far more highly than the ordinary sort; in Siam, indeed, the white elephant is royal and venerated. The catching of these elephants singly, or in herds, is by no means an easy task. In former years they were caught in pitfalls, but this practice has been abandoned, because the creatures were frequently injured. Modern methods are varied. Sometimes male elephants are decoyed by tame females trained for that purpose, until they are in close proximity to the hunters. These entangle their unconscious victim's legs in stout ropes, and when, eventually, he finds himself trapped, he fights until exhausted. When, however, herds are hunted, they are driven by an ever narrowing circle of hunters toward the mouth of a strongly built stockade, or "keddah." When, after many days, surrounded and enclosed by their pursuers, they rush into the stockade, the great gate is shut upon them. They are then tamed by a variety of methods, which differ, as the stockades do, according to locality. Once caught, the elephant is easily trained, a few months being, usually, sufficient to teach him all he needs to know. Methods of training vary in detail; but, after the first severe lessons, the trainer usually finds gentleness effective. The driver or mahout sits upon the elephant's neck and manages him by words and by the use of a small iron-pointed stick. Once tamed, elephants, except in cases where they become "bad," and have to be shot like mad dogs, are so gentle that children may be trusted to play with them.

Besides the differences between the two species, already noted, the African elephant is not as amenable to domestication and confinement as the Asiatic, and is the chief source of the world's supply of ivory. Indeed, the African elephant generally succumbs to disease and dies in confinement, while the only change noted in the Asiatic under the same circumstances, is that the species generally does not breed in captivity. The African elephant is peculiar in that the great tusks, twice as large as those of the Asiatic species, are present in both male and female, while in the Asiatic species they are found only in the male. Because of the demand for these, the African natives have made war upon the female as well as the male, and this leads naturally to a diminution of the species, as the number of tusks shipped has increased rather than decreased each year. The African elephant is now never used as a beast of burden, though in ancient Egypt he may have been so utilized.

Elephants generally live in large herds, each herd led, and apparently governed, by a leader, usually the largest of the party. So marked a family resemblance exists between members of the same herd that, in India — where they are classed as "high caste" and "low caste" — different herds are easily distinguishable. The African elephants live in mountainous regions, the Asiatic ones in deep forests, whence they can issue to play in and drink of the waters in which they find so much enjoyment. Here, too, their trunks are serviceable. They are used to squirt water over the creatures' backs, or to spout it, playfully at their neighbors. Elephants also caress each other by means of their trunks.

The anecdotes illustrating the docility, affection, sagacity, irritability, capriciousness, and revengeful spirit of the elephant, are innumerable, and may be found in various well-known books on natural history. The natural enemies of the elephant, beside man, are the tiger and the rhinoceros, and the nasal horn of the latter often proves a more formidable weapon than the trunk and tusks of the elephant, and the sight of even a dead tiger is said to be enough to excite most elephants into a transport of fury.

Fossil Elephants.— Mammoths, whose remains have been dug up, frozen or fossilized. The two living species of elephant are the last survivors of a group which formerly spread over all the great continents, and inhabited temperate and arctic as well as tropical regions. Various extinct species of the elephant, commonly called mammoths (q.v.), have been found in every country of Europe, in Asia, and Africa, and in the New World, from Alaska to Argentina. In Siberia their remains are so abundant that fossil ivory forms a considerable article of commerce. The mastodons (q.v.) distinguished from the true elephants by less specialized grinding teeth, had an almost equally extensive range, but inhabited more especially the temperate regions during the Pliocene and Pleistocene epochs. Primitive mastodons lived in Europe and North America during the Miocene Epoch; they were of smaller size than the later mastodons, and had two small tusks in both upper and lower jaws; these tusks have a band of enamel on the outer surface, and in the oldest species the upper tusks curve downward and the lower ones upward in a manner that indicates their origin from chisel-shaped incisors like those of rodents. The trunk in these primitive mastodons appears to have been much shorter than in the present elephant, and in every respect they were much less specialized. From this stage up to the present elephant a complete evolutionary series can be traced, but the earlier stages in the evolution of the *Proboscidea* are not known. It appears certain that they did not originate either in North America or Europe, but migrated to those regions during the Miocene Epoch, from some other continent. Prof. Osborn has considered them as probably of African origin; while Prof. Ameghino has recently announced his discovery of the early stages of their evolution in Argentina. The dinotherium (q.v.) of Europe was a side branch of the *Proboscidea,* contemporary with the primitive mastodons, and more primitive in the grinding teeth, but with more specialized tusks, the upper tusks being lost and the lower ones enlarged, while the reverse is the case in the mastodons and elephants.

Elephant, Order of the, an ancient Danish order of chivalry. It is said to have been instituted about the end of the 12th century by Canute VI. to perpetuate the memory of a Danish crusader who had killed an elephant in the Holy Land. It was renewed by Christian I. in 1462, and placed on its present footing in 1693 by Christian V. It is the highest of the Danish orders. The number of members, not counting those of the royal family, is restricted to 30. Foreign sovereigns are exempted from these restrictions. The fête of the order is held on 1 January, when the knights meet in the chapel of the order in the castle of Fredericksburg, taking rank by seniority upon seats over which are suspended their arms and devices. The insignia of the order are an enameled white elephant, with a negro mahout, bearing on a blue housing, bordered with gold and crossed with white, a sculptured tower. On state occasions the elephant is worn attached to a chain composed of elephants and castles of gold, with a letter D in gold to represent *Dania* (Denmark). The device of the order is *Magni animi pretium.*

Elephant-apple, a large and handsome East-Indian tree (*Feronia elephantum*). It be-

ELEPHANT BEETLE.

longs to the orange family, and produces a large gray-colored fruit with a very hard rind.

Elephant Beetle, one of the great cetonian beetles of the genus *Megasoma* of Central and South America; specifically *M. elephas.* It reaches a length of three to four inches, and is black, delicately pitted. A related species (*M. thersites*) occurs in California.

Elephant Fish (*Callorhynchus antarcticus*), a fish of the sub-class *Chimœroidea* or *Holocephali* (q.v.), found in southern seas, where it is the sole representative of its kind. The name alludes to the prominent projecting appendage of the snout. The young remain until an advanced stage of development within the remarkable horny egg-cases, where they are supplied by a current of water which enters and leaves by two pairs of orifices. The fish attains a considerable size and is sometimes eaten in New Zealand.

Elephant River, a river of Cape Colony, running into the Atlantic after a course of 140 miles.

Elephant Seal, the largest of the eared seals (*Macrorhinus leoninus*), usually over 20 feet long, with a circumference of 12 feet around the thickest part of the chest. The female is much smaller than the male. In color, this seal is grayish; its body is covered with short hair, growing in patches, which gives a spotted look to the animal. The head is proportionately large, with prominent eyes and thick eyebrows; the whiskers are long; and the canine teeth are so large as to form heavy tusks. The nose of the males is prolonged into a proboscis about a foot long, which, seemingly useless, hangs loosely over the face. When this is dilated, it gives a new character to the creature's voice. This species has been almost exterminated, owing to the demand for its oil, though less than a century ago it was plentiful in the southern hemisphere. The skin is not valued for its fur and the flesh is not edible. The herds migrate southward in summer and northward in winter to avoid the extremes of temperature.

Elephant-shrew, the typical species *Macroscelides,* of the family *Macroscelididæ,* belonging to the order of insect-eating mammals. The body, in general appearance and size, resembles that of the common rat. The popular name alludes to its peculiar, elongated nose, which looks like an elephant's trunk. The hind legs, which are long, and out of all proportion to the length of the fore legs, fit the animal for jumping, giving it the additional name of jumping-shrew. This insect-eater is confined to Africa. It moves by jumps, lives on the sandy plains, makes burrows in the sand, and finds its prey among the grass and bushes.

Elephanta, ĕl-ĕ-făn'tä, or **Elephant Isle,** called by the natives *Gharipur,* a small island in the Bay of Bombay, seven miles northeast of Bombay. It consists of two long hills and an intervening valley. It is celebrated for a cave temple 130 feet long, 123 broad, and 18 high, supported by pillars cut out in the rock. Many of these were cut down by the Portuguese. There are eight pillars or pilasters and in the centre is a gigantic trimurti or three-formed god — Brahma the creator in the middle, with Vishnu the preserver on one side, and Siva the destroyer on the other. There are other pieces of sculpture, and also several other rock-caves. The date of these constructions is not known. A large stone elephant, which once stood near the landing place, gave name to the island.

Elephantiasis, properly speaking, a peculiar and rare disease, sporadic or endemic in warm climates, and characterized by a chronic thickening of the skin and the underlying tissues, usually limited to a definite area, and subsequent to an impairment of the lymphatic circulation. The disease is of great antiquity, and exhibits a great variety of forms, by reason of which it has received a large number of names, medical as well as popular. The term is now applied by the best dermatologists to one disease, and not to several as heretofore. Elephantiasis exists in an endemic form in Africa, India, the Indian Archipelago, the West Indies, and South America. The recent territorial acquisitions of the United States bring this disease in their train. The endemic form of the disease commences rapidly. There is pain, heat, swelling, and temperature. The lymphatics and blood-vessels soon become involved, and the part affected seems to be attacked by erysipelas. In a few days the acute symptoms may subside. A recurrence of the attack leaves the arm, or leg, or scalp, or face, or genitals somewhat thicker, and repeated attacks may result in enormous deformities of the affected parts. In the most characteristic cases of the tropical countries the disease seems to be due to a blood parasite, the *Filaria sanguinis hominis.* This worm gets into the blood, at times through the agencies of mosquito bites, and blocks up the lymphatic channels. In other cases the disease is regarded as a form of chronic erysipelas. In a few instances it is congenital. The treatment will depend largely on the type of the disease. Rest in bed, elevation of the limb, quinine for the *Filaria,* and prompt medical attendance are the essentials. See FILARIASIS; PARASITES.

Elephantine, ĕl-ẹ-făn-tī'nē (Arabic, *Djezi-ret-ez-Zaher,* «isle of flowers»), a small island in the Nile, opposite Assouan (Syene), remarkable for the ruins with which it is covered. The island is almost covered with ruins piled up on each other — Egyptian, Roman, Saracen, and Arabic. At the beginning of the present century there were the remains of two temples in Elephantine, one a very interesting one built by Amunoph III. They were destroyed in 1822 by the governor of Assouan in order to obtain stone for building a palace. The greater part of the Nilometer, mentioned by Strabo, which stood at the upper end of the island, shared the same fate. The quay built of blocks taken mostly from older monuments, is from Roman times. Many fragments of pottery with inscriptions in Greek have been found, some of these being receipts for taxes.

Elephant's-ear, a name frequently given to plants of the genus *Begonia* (q.v.). It is applied specifically to a Hawaiian plant commonly known as *Caladium esculentum.*

Elephant's-foot, or **Hottentot's-bread** (*Tamus* or *Testudinaria elephantipes*), a plant of the yam order (*Dioscoreaceœ*), of which the rootstock forms a large fleshy mass, curiously truncate, or somewhat resembling an elephant's foot, and covered with a soft, corky, rough and cracked bark, recalling the shell of a tortoise, whence its other name. From this springs annually a climbing stem, which bears the leaves and flowers, these being small and yellow. The starchy rootstock is used as food by the Hottentots. The plant is not unfrequent in hothouses. The American plants known as elephant's-foot belong to the genus *Elephantopus* of the *Compositæ*. The genus comprises 14 species, natives of tropical or warm regions. Three are found in the United States, mostly to the south of Delaware. The best known is the Carolina elephant's-foot (*E. carolinianus*). This is an erect hairy herb, with thin oval leaves and bracted heads of blue or purple flowers in branching corymbs. It grows as far north as southern New Jersey, and west to Kansas, and is abundant in all the region to the south. Another species is known in the Southern States as tobacco-weed and devil's grandmother.

Eleusine, ĕl-ū-sī'nē, a genus of grasses comprising six species, all natives of the Old World. The genus is represented in America by *E. indica,* the crab-grass or yard-grass, which is found in waste places all over North America except in the extreme north, naturalized from Asia. In its native places it is an important article of commerce. *E. corocana,* called in the west of India natchnee, nagla, ragie, and mand, forms a principal article of diet among the hill people of the western Ghauts in India. It is cultivated also in Japan. *E. stricta* is also used for food.

Eleusin'ian Mysteries, festivals held annually at Eleusis, a town of Attica, in honor of the goddess Demeter, or Ceres, the patroness of agriculture, and procreative power of nature. The usual opinion is that they were begun by Eumolpus, the first hierophant, 1356 B.C. Great secrecy was observed in the celebration of the festivals, consisting of the greater and lesser mysteries. The greater mysteries were celebrated toward the end of September and 1 October, lasting nine days. The lesser mysteries took place at Agræ on the Ilissus during spring time. See Walter Pater, 'Greek Studies; Demeter and Proserpina'; Jacob Cooper, 'The Eleusinian Mysteries.' It was a capital offense to reveal any of the rites. They existed about 18 centuries, and ceased during the invasion of Alaric I., in 396.

Eleusis, ĕ-lū'sĭs, a ruined village of Attica, but in ancient times a city of Greece, 12 miles from Athens. It was celebrated as the chief seat of the worship of Ceres (Greek Demeter), whose temple here was the largest sacred edifice in Greece. The Greek government began here an elaborate system of excavations in the year 1882, with the result that many remarkable ruins have been discovered. A little village, poor and mean looking, called Leusina, stands on the site of what was once powerful Eleusis. Consult: Diehl, 'Excursions in Greece.'

Eleuthera, ĕ-lū'thĕ-ra, one of the largest of the Bahama Islands. It is like most of the islands of the group, long and narrow, its length being about 70 miles; area, 234 square miles. Its chief production is pineapples. Its chief town is Governor's Harbor. Pop. 7,200.

Eleutheria, ĕl-ū-thē'rĭ-a (Gr. ελευθερια, freedom), among the ancient Greeks, a festival commemorative of deliverance from the armies of Xerxes. It was instituted after the battle of Platæa (479 B.C.), and celebrated annually at that place in the month Maimacterion, nearly corresponding to our September. At the dawn of day a procession marched through the town, at the head of which trumpeters blew the signal for battle. At midday a chariot was driven toward the altar crowned with myrtle and various garlands, and leading behind it a black bull. In front of the altar the archon of Platæa immolated the bull to Jupiter and Mercury, eulogized the heroes who had fallen at Platæa, and sprinkled the ground with wine. Every fifth year these solemnities were attended by contests, chaplets being the reward of the victors.

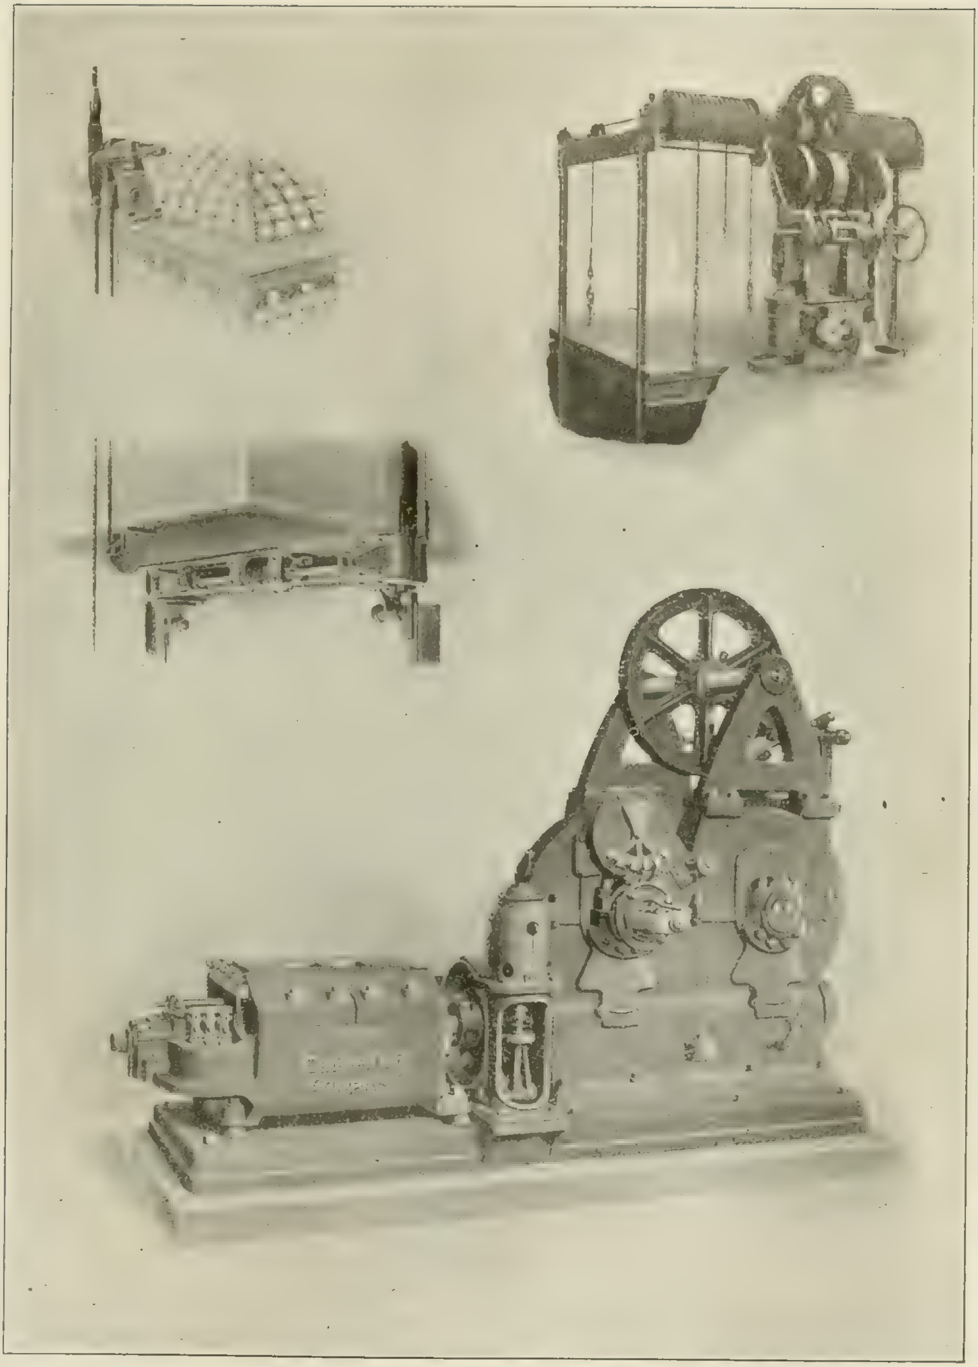
Elevated Railways. See RAILWAYS, ELEVATED.

Elevation, in the liturgy of the Roman Catholic Church, the act of lifting up by the celebrating priest and presenting to the sight of the faithful, the Host and the Chalice immediately after the consecration; this is the Elevation by eminence. There is both in the Latin and in the Greek Church liturgies another Elevation shortly before the communion. Prior to the promulgation and condemnation of the teaching of Berengarius in the 11th century, the Elevation after consecration appears to have had no place in the Latin liturgy; but from the beginning of the 12th century, when this custom was introduced, it spread rapidly and became universal and obligatory. It was the Church's way of confessing her faith in the truth of transubstantiation attacked by Berengarius. In the Latin Church in the 12th century began, and in the next century became universal, the custom of ringing a small bell at the moment of the Elevation, as is the present usage. But the ringing of the great bells in the church steeples and towers at the Elevation, which was pretty general in the 13th century, is now not common.

Elevation, in astronomy and geography, means generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian. In architecture, a geometrical delineation of the front or any face of a building in which all the parts are drawn according to scale and not shown as they would appear in perspective. It is one of the three designs necessary in outlining any work of architecture, the other two being the plan and the section.

Elevators. The modern elevator is a direct evolution from the machine which Elisha G. Otis exhibited in 1853 at the World's Fair in the Crystal Palace, New York. Hoists of various kinds had been built before that time, but this was the first elevator wherein provision was made for stopping the fall of the car in the contingency of the breaking of the hoisting cables. During the next five years, a number of machines were built similar to that exhibited, all being driven by belts from line shafting. In 1859 the same inventor introduced an

ELEVATORS.



For explanation, see article.

independent reversible engine directly connected to the hoisting machinery, and from that date the era of the elevator as a separate institution of the age began. In 1871 the hydraulic elevator was introduced, and thereafter was developed side by side with the steam machine. Finally in 1888, the electric elevator engine was introduced. There are, therefore, four general classes of elevators in use — hydraulic, electric, steam, and belt-driven. The great varieties of conditions encountered in elevator installation and operation has resulted in the development of a number of modifications of each of the four general types.

The type of elevator which is installed in greater numbers than any other is the vertical cylinder hydraulic machine. In this type, a cylinder of a diameter of, say from 8 to 24 inches (according to the water pressure and the load to be lifted), is placed in a vertical position in the elevator shaft or in any other convenient location. Within this cylinder works a piston. Attached to the upper end of the piston rods are the sheaves over which pass the hoisting cables. The length of the cylinder will, of course, depend upon the car travel and on the gearing. (See Fig. 1.) The car here shown is geared 4 to 1, although gears of 6 to 1 and 8 to 1 are quite common. For the ascent of the car, water under pressure admitted above the piston. For the descent of the car the pressure is shut off and the car descends by its unbalanced weight, the water above the piston flowing to the lower part of the cylinder through the pipe at the side known as the circulating pipe. The car is stopped at any desired point by closing a valve which both shuts off the water under pressure and closes up the path through the circulating pipe. Near the top of the circulating pipe is a simple device which limits to a predetermined maximum speed the rate at which water can flow into and out of the cylinder and therefore there is no possibility of the car moving at greater than the maximum speed in either direction.

The desired water pressure is generally obtained by suitable pumps which deliver through a pressure tank which takes up the pump pulsations. The method of controlling the valve from the car may be traced in the illustration. It will be seen that the hydraulic elevator engine is single-acting only — in fact, all styles of hydraulic machines possess this same characteristic, the car descending by its unbalanced weight (except in the pulling plunger type later to be described). It is customary with hydraulic elevators to partially counterbalance the weight of the car, leaving uncounterbalanced only sufficient weight to enable the car to descend at a proper speed.

Continuing the discussion of hydraulic elevators — in certain situations it is desirable to place all of the elevator machinery in the basement, and in such instances the cylinder is placed in a horizontal position. The horizontal cylinder hydraulic engine may be of either the "pushing" pattern wherein the car is raised during the outward stroke of the piston or the "pulling" pattern wherein the work is performed while the piston is being forced inward.

In the design of the modern city building it is highly desirable that as little space as possible be lost for rental purposes and the elevator builders have responded to this requirement (which is continually becoming more urgent) by designing a high pressure machine which is much more compact than any other type of hydraulic elevator. By using a high pressure — 700 to 800 pounds per square inch — the size of the entire apparatus including the hydraulic system and pipes can be greatly reduced. The cylinder is suspended in an inverted position so that the plunger, which works therein, on being forced downward causes the car to ascend, as may readily be seen by inspection of the illustration. The high pressure hydraulic engine is also made with horizontal cylinder designed to be placed in the basement. In fact, the horizontal high pressure type is the latest development in elevator engineering. To maintain the pressure necessary for the operation of this system an accumulator of the weighted type is substituted for the pressure tank used in the low pressure systems. The motion of the accumulator governs the pumps, controlling the delivery of water in accordance with the requirements of the service. This is accomplished either by mechanical connections to the steam valves, or by a series of switches when the pumps are driven by electric motors.

The pulling plunger type of hydraulic elevator differs from any other in that when lifting the load it does not consume water, but discharges it from the cylinder. In this elevator the weight of the plunger itself, which is of solid steel, lifts the load, the plunger descending into the cylinder as the car rises in the hatchway. For the descent of the car, the water is admitted at the required pressure under the plunger and, assisted by the weight of the car, raises the plunger and the car descends. The remaining class of hydraulic elevators is the plunger or direct lift type. In this type, a cylinder of a length equal to the car travel is set vertically in the ground. In this cylinder works a plunger of the same length, carrying the car on its top. Water is admitted to and discharged from the cylinder at the top, the annular space around the plunger affording ample passageway for the water. As usual, water under pressure is admitted to the cylinder for the ascent of the car and for the descent is allowed to run out.

Electric Elevators.— The construction of a modern electric elevator engine may be described as follows: A motor is connected to suitable winding machinery by means of a worm shaft (a continuation of the armature shaft) engaging with one or two worm wheels, the latter being rigidly connected to the winding drum (in the case of elevators for ordinary freight or passenger service) or connected by means of suitable gearing (for hoists of very large capacities). On the armature shaft and worm shaft a brake wheel is mounted. A brake band is normally held tightly against this wheel by a heavy spring, thus locking the elevator engine. On starting the motor, current is also admitted to a solenoid, the action of which removes the tension from the brake band, allowing a free movement of the motor shaft. On the stopping of the current, the brake is instantly applied by the spring.

Various electric controlling devices have been used with electric elevators. The one most generally used as being the most perfect, operates on the following principle:

On starting the car, the attendant therein moves the lever or switch (as the case may be). This movement admits starting current only to the motor, and thereafter the operations are entirely automatic. As the motor accelerates, the starting resistance is cut out step by step automatically by a series of magnets and thus the current is absolutely prevented from increasing above the amount for which the motor is designed, and a gentle and uniform acceleration is secured. Fig. 2 shows a standard magnet controller for passenger service. In machines of the smaller capacities, there is but a single worm wheel and the end thrust is taken up by ball bearings at the extremity of the worm shaft. In the larger machines, there are two worm wheels, the thrusts of the two compensating each other. Fig. 3 shows a standard electric elevator engine for high-speed passenger service. By proper proportioning of the capacity of the motor and by using a suitable train of gears electric engines may be designed for special, heavy service, and numerous incline railways in various parts of the country for handling teams, passenger cars, and hoists for heavy mine and blast-furnace work, etc., are operated by electric engines working on a principle similar to that above outlined.

The electric elevator with push-button control, is a type designed particularly for private residences. (See Fig. 4.) No attendant is required and the elevator is always ready for service. A passenger desiring to use the elevator presses a button placed near the elevator shaft, and the car, if not in use, immediately travels to that floor and stops automatically. When the car has come to rest at that floor, the door can be opened.

After having entered the car and closed the door, the passenger presses a button corresponding to the floor to which he wishes to travel and the car at once proceeds thereto and the door at that floor can then be opened. After the passenger has left the car, and closed the door, the car may again be summoned from any of the floors as before. In addition to its wide-spread use in private residences, this type of elevator is frequently used in hospitals and apartment houses where it is desired to dispense with an operator.

In the duplex motor electric elevator (Fig. 5) the drum is dispensed with and a sheave is placed on the end of each of the two armature shafts and endless cables pass round these sheaves and are connected to the car and also to the counter-weights by running sheaves. The motors run in opposite directions, and as one or the other of the motors accelerates, the car moves up or down in the hatch-way, its speed being proportional to the difference of speed of the two motors. When both motors are running at the same rate of speed the car is stationary. This type of electric elevator is particularly suitable for the service in which long car travel, fast car speed and rapid reversals are essential features.

Steam machines may be dismissed with simply a reference, as machines of this class are seldom installed now except for freight purposes, having been replaced for passenger service by the newer hydraulic and electric types. In Fig. 6 is shown a new type of steam hoist designed particularly for use on board ships. A marked economy in loading and unloading has resulted in those vessels where these hoists have been installed. The particular hoist illustrated herewith has a capacity of 4,000 pounds net load at a speed of 100 feet per minute, the size of the platform being 7 by 10 feet. Hoists of this character, however, can be made any desired power. The engine can be fitted with an automatic device whereby, at the beginning of a loading operation, the engine is automatically brought to a stop when the platform reaches the lowest deck. When this deck is completely loaded, the device is readjusted to stop the engine automatically, when the platform is lowered to the next deck, and so on. When all the decks are completely loaded, the platform is lowered to the bottom of the hatchway. The main winding drums are then thrown out of gear and the auxiliary hoist, which can be seen in the illustration, becomes operative. The hatchway may then be filled with cargo by means of this auxiliary hoist. In unloading, these operations are, of course, reversed. Belt elevators consist of winding machinery geared to pulleys whereby they may be driven from a countershaft. Machines of this type are comparatively inexpensive and are used extensively for freight purposes in factories.

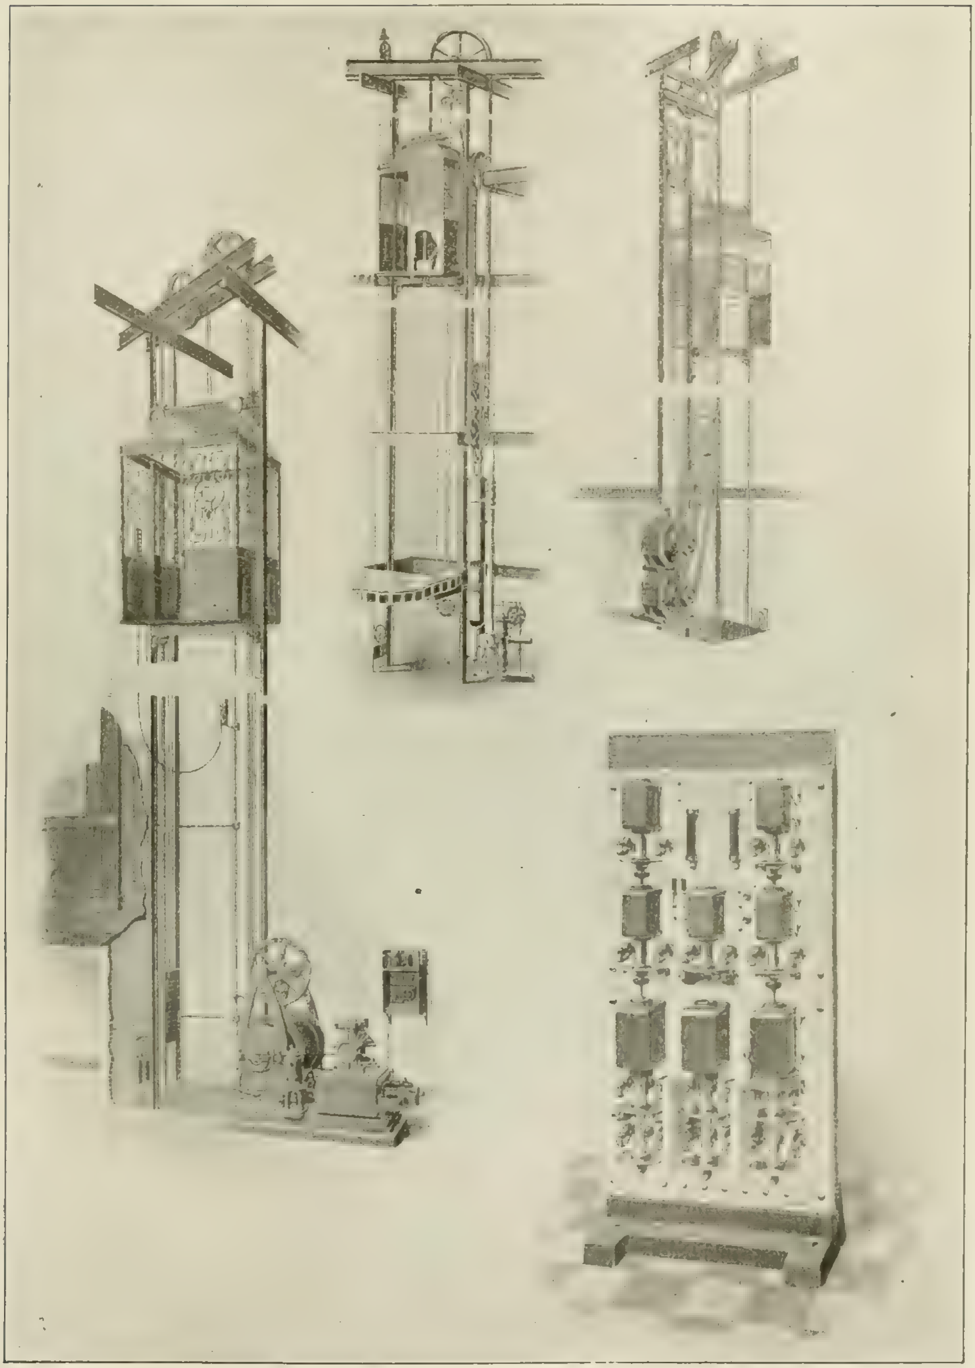
While the factor of safety in the standard make of elevators is such that accidents very rarely occur and practically never where proper attention is paid to the elevator machinery, still all elevators are equipped with standard safety devices. The safety devices consist primarily of a governor of the centrifugal type which is connected to the car entirely independently of the hoisting cables. In the contingency of the car, for any reason, exceeding the speed for which the governor has been set, the governor rope which normally runs freely is tightly clasped and the drum under the car is rotated and the powerful grips such as may be seen in the illustration (Fig. 7) come into play, bringing the car to a safe and easy stop.

THOMAS E. BROWN,
Chief Engineer Otis Elevator Co.

Elf, a little sprite of human form supposed to inhabit wild and desolate places, and to exercise a mysterious power over man; a fairy, a goblin.

Elf-arrows, Elf-bolts, Elf-shot, are the names given to implements of stone, especially flint, of various sizes and forms, which are found abundantly in many countries, and are the remains of arrow-heads, darts, and other rude ancient weapons from the Palæolithic Period. They belong to the same class of ancient implements as are described in our article CELTS (stone hatchets). These rude and ancient implements are objects of some extraordinary superstitions. The names given above are, of

ELEVATORS.



For explanation, see article.

course, of popular and comparatively modern origin, and imply that those who gave them were completely ignorant of the real origin and use of those weapons. These names are found independently among the peasantry in Scotland, England, and Ireland, and the superstitions associated with them are much more widely spread. Acording to the popular belief the stones are of supernatural origin, and various virtues are attributed to them. They are worn as charms, and used as a protection against lightning; but they are chiefly suspected of mischievous consequences. A cavern has been pointed out where the archfiend carries on the manufacture with the help of attendant imps, who rough-hew them while he finishes the work. Similar superstitions prevail in Italy, Africa, and Turkey. Consult: Evans, 'Ancient Stone Implements of Great Britain.'

Elgar, Edward William, English composer: b. Broadheath, Worcestershire. Among his compositions are: 'The Black Knight' (1892); 'Choral Suite: from the Bavarian Highlands' (1895); 'Lux Christi,' produced at the Worcester Festival (1896); 'Te Deum,' sung at the Hereford Festival (1897); 'Caractacus,' produced at the Leeds Festival (1898); 'Sea Pictures,' for the Norwich Festival (1899); 'Dream of Gerontius,' for the Birmingham Festival (1900); 'Coronation Ode' (1902).

Elgin, ĕl'gĭn, **James Bruce,** 8TH EARL OF, and 12TH EARL OF KINCARDINE, English statesman: b. London 20 July 1811; d. Dhurmsala, North India, 20 Nov. 1863. He was educated at Eton and Oxford; in 1841 entered Parliament as member for Southampton, and in the same year succeeded to the earldom. In 1842 he was appointed governor of Jamaica. His rule in Jamaica was so successful that in 1846 he was appointed governor-general of Canada, and there he succeeded by a conciliatory policy in allaying the discontent which had broken out and for some time continued. In 1849 he was raised to the British peerage as Baron Elgin; was sent in 1857 as special ambassador to China, where in the following year he succeeded in concluding the Treaty of Tientsin. He also concluded a treaty with Japan. In 1860, the Chinese emperor having manifested unfriendliness, Lord Elgin was sent to enforce the treaty, which he did by entering Peking in state and destroying the imperial summer palace. Immediately thereafter, in 1861, he was appointed governor-general of India. He maintained internal peace, and exerted himself unceasingly for the development of the country.

Elgin, Thomas Bruce. See BRUCE, THOMAS; ELGIN MARBLES.

Elgin, Ill., a city of Kane County, 36 miles west by north of Chicago. Two railroads supply adequate shipping facilities, the Chicago, M. & St. P., and the Chicago & N. It is also the terminus of the Aurora, Elgin & Chicago Railway, which is a third-rail electric line between these cities, and is the finest road of its kind in existence.

Industries, etc.— Two products make Elgin famous — butter and watches. The dairy interests have probably had more to do with the development of the community than any other factor. Early in its history, The Borden Condensed Milk Company located a large plant here and since that time has established many more in the immediate vicinity. The current quotations of the Elgin Board of Trade fix the market price of high grade butter throughout the entire country. The other industry to which Elgin largely owes its growth and prosperity is the making of fine watch-movements. The watch factory was started in the spring of 1864, and has been a success from the beginning. There are many other industries in Elgin, all of which are prosperous concerns. Two watch-case factories and as many shirt factories distribute their products throughout the country. Besides these, there are shoe, pipe-organ, automobile, coffin-fixtures, canning, malted-milk, and rug factories. Two large publishing houses are located here, and there are several machine shops and foundries.

Public Institutions, Buildings, etc.— Elgin is sometimes called the "City of Churches." Nearly all denominations are represented and the various houses of worship are large and handsome. The city is noted for its public school system, which is highly developed and very efficient. The buildings are handsome in architecture and a new high school is in the process of construction. The Elgin Academy of the Northwestern University is a well-known preparatory school for the latter institution, which is located at Evanston, Ill. Saint Mary's Academy is also well known throughout the State and bears a high reputation as a place of learning. The Illinois Northern Hospital for the Insane is located in Elgin. The Elgin Woman's Club has built and now operates a hundred-thousand-dollar hospital, which is famed throughout the country and State for its high standing and great efficiency. Three daily papers are published in the city, the *Daily News* leading in circulation and standing. The banks are six in number, four national and two savings. They have a combined capital of $650,000 and are prosperous and strong financial institutions.

History, Government, etc.— Founded in the spring of 1835, Elgin has grown rapidly in size and importance until it now is the most beautiful and the second largest city in Kane County. Elgin was incorporated in 1854 and Dr. Joseph Tefft was chosen the first mayor. The waterworks and sewer system and an electric lighting plant are the property of the municipality and its bonded indebtedness is small. Property is in great demand, owing to the number of Chicago people who, on account of good transportation facilities, are seeking more room and pleasanter homes within the confines of the beautiful city on the Fox. Pop. (1890) 17,823; (1900) 22,433.

RICHARD LOWRIE,
Of the 'News Advocate.'

Elgin Marbles, the name given to a peerless collection of antique sculptures brought from Athens to England by Thomas Bruce, 7th Earl of Elgin, in the early part of the 19th century. While ambassador at Constantinople (1799–1802) he conceived the plan of securing some portion of the ruins of ancient Athens, and to that end secured permission of the Porte to take "any stones that might appear interesting to him." At his own expense (the British government having refused any aid) he set a corps of artists to work who toiled for 10 years detaching various specimens from the

Parthenon, consisting chiefly of the colossal statues on the tympana of the pediments, the metopes and the frieze around the cella. Among the best preserved examples which this splendid effort brought forth were the tympanum representing the birth of Minerva, the 15 metopes showing in high relief the combats of the Centaurs and Lapithæ and the slabs from the cella frieze depicting in low relief the great Panathenaic procession. In addition to these Lord Elgin procured the colossal statue of Bacchus from the choragic monument of Thrasyllus, one of the caryatides from the temple of Pandrosus, a portion of the frieze from the Erechtheum, and fragments of the columns of the Parthenon and Erechtheum; also numerous inscriptions, urns, etc., found in the neighborhood. When these treasures of antiquity arrived on the English shores they were received with a mixture of admiration and indignation — the latter because of supposed vandalism. It is said that Lord Byron was so outraged by the alleged depredations that when he visited the Parthenon he inscribed conspicuously: *Quod non fecerunt Gothi, hoc fecerunt Scoti.* However, as it afterward proved, had not Lord Elgin obtained these sculptures they would have been destroyed in the subsequent war of Greek independence, and especially in the last siege of Athens in 1826–7. After much hesitation, and bickering as to the price, in spite, too, of their value vouched for by experts, the British Parliament purchased the marbles from Lord Elgin for £35,000, easily a third less than he had expended upon them. They are now to be seen in the British Museum as priceless examples of the highest in Greek art which matured under the glorious genius of Phidias. Many casts have been taken of these unsurpassed relics of which the city of New York possesses a set.

Eli, ē'lī, Hebrew judge and high-priest of Israel. After a turbulent rule of 40 years, he died 1116 B.C. Failing to punish the misdoings of his sons, Phineas and Hophnai, the downfall of his house followed.

Eli Perkins. See LANDON, MELVILLE D.

Elia, ē'lĭ-a. See LAMB, CHARLES.

Elie de Beaumont, Jean Baptiste Armand Louis Léonce, zhŏṅ bäp-tēst är-mäṅ loo-ē lā-ôṅs ā'lē dė bō-môṅ, French geologist: b. Canon, France, 25 Sept. 1798; d. there 22 Sept. 1874. He was educated in the Polytechnic School; became professor at the School of Mines 1829; professor of geology in the College of France 1833; chief engineer of mines 1833; member of the Institute 1835; and perpetual secretary of the Academy of Sciences 1853. He published 'Carte géologique de France' (1843); 'Notices sur les systèmes de montagnes' (1852), etc.

Eligius, ĕ-lĭj'ŭs, or **Eloi**, ā-lwä, **Saint**, bishop of Noyon: b. Cadillac, near Limoges, 588; d. Noyon 1 Dec. about 660. Having in boyhood shown a decided aptitude for fine art he was placed by his parents under the direction of the master of the mint at Limoges, and there acquired skill in the goldsmith's craft. Appointed coiner to the Frankish king, Clotaire, and to his son and successor, Dagobert, he executed at their order the bas-reliefs on the tomb of St. Germanus, bishop of Paris, and other works in the precious metals which were regarded as the masterpieces of decorative art in that time. He was a favorite at court, which he was obliged to frequent because of his connection with the king; but he took more pleasure in relieving the needy than in the society of the worldly. He daily fed a large number of poor people, he buried the bodies of malefactors, and he ransomed captives, especially the Saxon slaves who were often sold in the markets. Both Clotaire and his son Dagobert bestowed costly presents upon Eligius, but they could not make him rich, he gave so much to the poor and to the founding of charitable institutions. At about the age of 50 he decided to abandon the world entirely and devote himself to the conversion of the pagans. Two years later he was ordained priest and in 546 was made bishop of Noyon. As bishop he gave special attention to the conversion of the Flemings and Frisians, and the greater part of Flanders was converted through his efforts. See Lebeuf, 'Histoire du diocese de Paris'; Fleury, 'Vita S. Eligius.'

Elijah, whose name («Jehovah is God») indicates his mission and his work, was one of the greatest prophets of Israel. His prophetic activity began in the days of Ahab of Israel, and ended in the days of his son, Ahaziah, or, as is on the whole, more probable, in the days of his son-in-law, Jehoram of Judah. His first appearance is strange; the end of his life on earth still more strange. Throughout his career he comes and goes in an unusual and remarkable way. His special work was to save his nation from falling into heathenism, and thus making impossible the great history which has resulted in the Christian civilization of our own days. Ahab, the king of northern Israel, had married Jezebel, the daughter of Ethbaal, king of Tyre, and formerly a priest of the Tyrian religion. Among the Semitic peoples an alliance of nations meant a mutual honoring of gods. Thus the marriage of Ahab and Jezebel introduced into the kingdom of Israel the worship of the Tyrian Baal. Gradually, through the determined efforts of Jezebel, who was a fanatic for her faith, the worship of Baal displaced that of Jehovah, and seemed likely altogether to destroy it. Later, by the marriage of Athaliah, the daughter of Ahab and Jezebel, to Jehoram, king of Judah, the same course of things began in the kingdom of Judah (2 Kings viii. 18). To bring back the nation to the worship of Jehovah, and to the recognition of him as God, was the work of Elijah. This work began with the sudden appearance of the prophet to Ahab, to announce to him the coming drought and famine, which the nature god Baal would be powerless to prevent (1 Kings xvii. 1). The life of the prophet up to this time had probably been spent in the lonely and wild region on the eastern side of the Jordan, although it is uncertain where his birthplace was. During the three years and more of drought and famine which followed Elijah's first appearance to Ahab, the prophet found a home and the means of life, first by the brook Cherith, and afterward in the home of a widow in Zarephath, a city of Phœnicia. At the end of this time he had his great contest with the prophets of Baal on Mount Carmel, where, in answer to his prayer, Jehovah revealed himself by fire, and was acknowledged by the people to be God. The same day the

CHARLES WILLIAM ELIOT

PRESIDENT OF HARVARD UNIVERSITY

falling rain ended the drought and the famine (1 Kings xviii.). The triumph of the prophet was followed by a flight to Mount Horeb to escape the wrath of the angered Jezebel. On this mountain he received from God a revelation in regard to the real part his work had in the history of his nation, and was commanded by God to call Elisha to be his successor in the work for the nation. In obedience to this command, he went from Horeb to Abel-meholah, the home of Elisha. Having given to Elisha the call to be his successor, he disappeared for a time from the view of men (1 Kings xix.). About six years later, the prophet again appeared to Ahab in the vineyard of Naboth, in Jezreel, to denounce him for his wicked disregard of the rights of his brother, made sacred by the law of Jehovah (1 Kings xxi. 17–24). The final work of the prophet on behalf of his people is recorded only in the book of Chronicles (2 Chron. xxi. 12–15). This was the sending of a letter to Jehoram, the king of Judah, to tell him that, because he had endeavored to introduce the Baal worship of the northern kingdom into Judah, and because he had cruelly murdered his brothers to make his own throne more secure, Jehovah would send great evils upon his people, his family, and himself.

How long the prophet lived we do not know; but, at the last, the man of storm and whirlwind was, by a whirlwind and without death, taken up to his God (2 Kings ii. 1–12).

(1902); Strachan, article 'Elijah' in Hastings' 'Dictionary of the Bible' (1899).

Sylvester Burnham,
Professor of Old Testament Interpretation, Theological Seminary of Colgate University.

Elijah, The, an oratorio by Mendelssohn, first performed at Birmingham, England, 26 Aug. 1846. It is one of his best-known works and is more popular in England and America than any other oratorio, with the exception of Handel's 'Messiah.'

Elimina'tion, the separation and exclusion of some particular substance from a compound, or of some particular symbol from an algebraic expression, thus simplifying the compound or expression, and rendering it capable of further analysis and use. It is a process by which, where we have a number of statements concerning several quantities, we can obtain a separate statement concerning each. Thus, in mathematics, broadly speaking, elimination is the operation which consists in getting rid of a common quantity. See 'Theory of Equations' (1901), Burnside and Panton.

Eliot, Charles William, American college president: b. Boston, Mass., 20 March 1834. He was graduated from Harvard in 1853, was tutor in mathematics there 1854–8, and assistant professor of mathematics and chemistry in the Lawrence Scientific School, Harvard, 1858–63. After spending two years in Europe investigating educational methods he was professor of analytical chemistry in the Massachusetts Institute of Technology 1865–9. In the last-named year he became president of Harvard University, which position he still holds. He is one of the foremost writers and speakers of the day upon educational and social problems and has exerted a strong influence upon the trend of American thought. He has published 'Manual of Qualitative Chemical Analysis' (with F. H. Storer); 'Manual of Inorganic Chemistry' (with F. H. Storer); 'Five American Contributions to Civilization and Other Essays'; 'Educational Reform.'

Eliot, George (pseudonym of Mary Ann or Marian Evans Cross), English novelist: b. Arburyfarm, near Nuneaton, Warwickshire, 22 Nov. 1819; d. Chelsea, England, 22 Dec. 1880. She received her early education at Attleborough, Nuneaton, and Coventry, and sooner or later, either under the tuition of masters or by teaching herself, acquired a knowledge of Greek, Latin, French, German, and Italian; she also studied Hebrew, and for some time devoted herself to the study of music, becoming an excellent piano player. She was also a constant and omnivorous reader. Shortly after her 21st year she came into personal contact with friends who held rationalistic views in regard to religious matters, and though she had previously been attached to the doctrines of the evangelical school (she had an aunt who was a Methodist preacher), her religious views now underwent such a change as to cause a breach between her and her father which seems never to have been entirely closed up. Her first literary undertaking was the continuation of a translation of Strauss' 'Life of Jesus,' commenced by her friend Mrs. Hennell, and completed by Miss Evans in 1846. In 1849 she went abroad, returning to England next year, and in 1851 took up her abode as a boarder in the house of John Chapman, editor of the 'Westminster Review.' This connection led to her being attached to that periodical as sub-editor. Various articles in the 'Review' from 1852 onward have been attributed to her, but her principal work appears to have been the writing of the summaries of contemporary literature. It was not, however, until January 1857 that she came prominently into public notice, when the first of a series of tales entitled 'Scenes from Clerical Life' appeared in 'Blackwood's Magazine.' These tales immediately arrested attention, and obtained the praise of the editor, who was informed that he was to know the author as George Eliot. Mr. John Blackwood was as ignorant of the author's identity for a considerable time as was all the world except George H. Lewes (q.v.), and one or two others. The 'Scenes' came to an end in November 1857, and in the February following, the first chapters of 'Adam Bede' were in the publisher's hands, the whole work being completed and sent in by October. The success which attended the publication of this powerful story of English rural life was unmistakable, and public curiosity was greatly excited as to the personality of the author. The credit of authorship was openly ascribed to various persons of more or less note and was claimed by others of more or less modesty and honesty. The secret soon began to leak out. Months before her second novel, 'The Mill on the Floss,' was published (1860) it was well known, among literary circles at least, that George Eliot was none other than Marian Evans, the Westminster reviewer. By this time was established that close association and literary fellowship with the talented philosophical writer, George H. Lewes, which terminated only with the death of the latter but a little more than two years before her own. In 1861 was published 'Silas Marner,' another story of humble country life, a painful, but powerful and interesting tale. Two years later she gave to the world 'Romola,' an historical novel of Italian life in the time of Savonarola, which is considered by a select few as her greatest intellectual achievement. This was followed by 'Felix Holt,' a story dealing with political, social, and religious peculiarities (1866); 'Middlemarch,' somewhat weak and diffuse as a story, but replete with pregnant thought and clear delineation of character (1871); and 'Daniel Deronda,' containing some striking and original sketches of Jewish life and character (1876). Previous to this she had acquired some renown as a poet through the publication of several volumes of poems, among which may be mentioned: 'The Spanish Gypsy' (1868); 'Agatha' (1869); and 'The Legend of Jubal' (1874). Her last work was a series of essays, entitled the 'Impressions of Theophrastus Such' (1879). In May 1880 she married Mr. John Cross, but died rather suddenly at Chelsea on 22 December of that year. Her 'Life, as Unfolded in Her Letters and Journals,' was published in 1885 by her husband. See also: Dowden, 'Studies in Literature' (1878); Blinde, 'George Eliot' (1883); James, 'Partial Portraits' (1888); Parkinson, 'Scenes from the George Eliot Country' (1888); Stephens, 'George Eliot' (1892); Myers, 'Essays Modern' (1883); Hutton, 'Modern Guides of English Thought' (1887).

Eliot, Sir **John,** English orator and states-clergyman: b. 7 Nov. 1685; d. 22 April 1763. He was a grandson of John Eliot, the «Apostle to the Indians,» and was long pastor at Killingworth, Conn. He was an able preacher, a botanist, and a scientific and practical agriculturist, was the first to introduce the white mulberry tree into Connecticut, and discovered a process of extracting iron from ferruginous sands. He was also regarded as the first physician of his day in the colony; and such was his success in the treatment of insanity and chronic complaints, that he was sometimes sent for to Newport and Boston, and was more extensively consulted than any other physician in New England.

Eliot, Sir **John,** English orator and statesman: b. Port Eliot, Cornwall, 20 April 1592; d. London 27 Nov. 1632. He entered Parliament in 1614 as member for St. Germans, winning immediate reputation as an orator. As vice-admiral of Devon he was energetic in suppressing piracy. In the three parliaments of 1623, 1625, 1626, he made his way to the front of the Constitutional party, joined Hampden and the rest in refusing contributions to the forced loan, and took a prominent share in the impeachment of Buckingham and in drawing up the 'Remonstrance and Petition of Right.' He was imprisoned in the Tower in 1629, and died there three years later. During his imprisonment he wrote a work on constitutional monarchy, entitled the 'Monarchy of Man,' and several other works, including an account of the first Parliament of Charles I. under the title 'Negotium Posteriorum' a vindication of his public conduct, entitled 'An Apology for Socrates'; and 'De Jure Majestatis,' a treatise on government. Eliot was not a Republican, but believed in constitutional monarchy, and all through his career boldly maintained the privileges of Parliament both in its individual members and as a legislative and executive body. See 'Life' by Forster (2d ed. 1871).

Eliot, John, American colonial missionary, «the Indian Apostle»: b. probably at Widford, Hertfordshire, 1604; d. Roxbury, Mass., 20 May 1690. He was graduated at Cambridge in 1622, and, after taking orders in the Church of England, quitted his native country for conscience's sake, and landed at Boston, New England, in 1631. In 1646, after two years study of the Indian language, he delivered a long sermon in the native dialect at Nonantum, and other meetings soon followed. He shortly after began to establish his converts in regular settlements, his work meeting with approval both in the colony and at home; in England a corporation was founded in 1649 «for the promoting and propagating the Gospel among the Indians of New England,» which defrayed the expenses of the preachers and the cost of printing translations. At one time there were over a dozen townships of «praying Indians» within the bounds of Massachusetts, and many more outside these limits, with numbers estimated in 1674 at 3,600; but, although the organization survived until the death of the last native pastor in 1716, the decay of the «praying towns» was rapid after the war with King Philip (1675), in which the converts suffered equal cruelties at the hands of their countrymen and of the English. There are monuments to Eliot's memory in the Indian burying-ground at South Natick, and at Newton, near the scene of his first Indian sermon. A man of earnest piety and devotion, warm-hearted, and of a singularly attractive manner, he has left a memory that is honored among the first in the history of New England. With Thomas Weld, and Richard Mather, Eliot prepared an English metrical version of the Psalms, the 'Bay Psalm-book' (Camb. 1640), as the first book printed in New England. He was also the author, among other works, of: 'The Christian Commonwealth' (Lond. 1659), suppressed by the general court, and now extremely rare: 'The Communion of Churches' (1665), the first book privately printed in America; and of translations into the Indian tongue of Baxter's 'Call'; Bayly's 'Practice of Piety' (abridged); and Shepard's 'Sincere Convert.' But the great work of his life was the translation of the Bible into the tongue of the Indians of Massachusetts (Algonquin), of which the New Testament appeared in 1661, and the whole work, with a version of the Psalms in metre, and a page of «catechism» in 1663. The longest single word in it is «Wutappesittukqussunnoohwehtunkquoh,» signifying «kneeling down to him,» in Mark i. 40; which illustrates the jest of Cotton Mather, who said he thought the words of the language must have been growing ever since the dispersion at Babel. Only 14 complete copies of the first and second editions are known to be in existence. A scientific study of Eliot's Indian Bible was made by J. H. Trumbull (q.v.), and his MS. published 1903 as 'Bulletin 25' by the Bureau of American Ethnology, Washington. Its title is the 'Natick

From the etching by Rajon

GEORGE ELIOT.

Dictionary,' and it is divided into two parts, the first giving the Natick words with English definitions and the second giving the English words with Natick definitions. In other words, the volume contains two dictionaries, one Natick-English and the other English-Natick. While it is devoted to the Natick language it is practically a dictionary of all the Algonquin languages of Massachusetts, for the tribes of that part of the country spoke practically the same language, though each had its dialectic variations. Eliot's 'Indian Grammar Begun' was printed in 1666; his 'Indian Primer' in 1669. The finest collection of unique and scarce copies of Eliot's works is in the Lenox Library, New York; many of them have been reprinted. The best 'Life of Eliot' is that by Francis in Volume V. of the first series of Sparks' 'American Biography' (1836); the earliest that by Cotton Mather 1691; consult also articles in the 'Cyclopædia of American Biography' (Vol. II. 1887); and the 'Dictionary of National Biography' (Vol. XVII. 1889).

Eliot, Samuel, American educator and historian: b. Boston, Mass., 22 Dec. 1821; d. Beverly, Mass., 14 Sept. 1898. He filled the chair of history and political science in Trinity College, Hartford, Conn., 1856–64; was president of Trinity College 1860–4; and overseer of Harvard 1866–72. Among his publications are: 'The History of Liberty' (1853); 'The Liberty of Rome' (1849); 'Life and Times of Savonarola' (1856); 'Manual of United States History Between the Years 1492 and 1850' (revised ed. 1873); and 'Stories from the Arabian Nights' (1879).

Eliot, Samuel Atkins, American Unitarian minister: b. Cambridge, Mass., 24 Aug. 1862. He was graduated at Harvard College 1884; was pastor of Unity Church, Denver, 1889–93, and of the Church of the Saviour, Brooklyn, 1893–8. He was secretary of the American Unitarian Association 1898–1900, becoming its president at the latter date.

Elis, ē'lĭs, (1) A country in the west of Peloponnesus, where Olympia was situated. It was bounded on the east by Arcadia, on the south by Messenia, and ran along the coast, watered by the river Alpheus. Elis and Archaia now form a monarchy of Greece. (2) Elis, the capital of Elis, is now called Kaloskopi. See OLYMPIA; OLYMPIC GAMES. Consult: Curtius, 'History of Greece.'

Elise, or **San Antonio Colony,** Paraguay, an agricultural settlement started in 1890, situated in the department of San Lorenzo de la Frontera, on the left bank of the Paraguay River, about nine miles from Asunción. Products: tobacco, sugarcane, coffee, ramié grass, etc. See PARAGUAY.

Elisha, a member of the tribe of Issachar, a citizen of Abel-meholah, was a disciple of Elijah, and his successor in the prophetic office. His prophetic ministry, which was exercised, as was that of Elijah, in northern Israel, began in the reign of Ahab, and continued through the reigns of Jehoram, Jehu, Jehoahaz, and during a part of the reign of Joash, thus covering a period of more than half a century. He was a man of very different character and mode of life from Elijah, although master and disciple seem to have been most warmly attached to each other. Elijah was a son of the desert; Elisha came from a quiet farm in the Jordan valley. Elijah lived apart from men; Elisha, for the most part, dwelt in the city, either at Jericho among the sons of the prophets, or in his own home at Dothan or Samaria. Elijah had nothing to do with kings except to rebuke them; Elisha was their friend and counsellor. Yet it is easy to make too much account of their difference of character and life, and to suppose that it affected essentially the prophetic aim and religious attitude, so that these were quite different in the case of each prophet. But to claim that the work and spirit of Elisha were in marked contrast to those of Elijah would be to claim too much. The declaration of Jehovah to Elijah on Mount Horeb, "Him that escapeth from the sword of Jehu, shall Elisha slay" (1 Kings xix. 17), shows that it was Elijah's work of vengeance and destruction which Elisha was to continue. It was Elisha, moreover, who devised the plan for the destruction of the house of Ahab (2 Kings ix. 1–3). It was Elisha, also, who reproved King Joash for his lack of zeal for the utter overthrow of Syria (2 Kings xiii. 19). It is to be remembered in this connection that the accounts which we have concerning the career of Elisha, whatever the cause may be, relate rather to his deeds as a man, than to his work as a prophet.

For some six or seven years after his call to the office of prophet by Elijah at Abel-meholah (1 Kings xix. 19–21), he was a helper and disciple of Elijah. But we do not know just where he was in all this time, or the exact nature of his work. At the close of this time, after the ascension of Elijah, he began his own independent work as a prophet (2 Kings ii. 13–22). The character of the narrative in the Second Book of Kings makes it impossible to arrange the events of his life in chronological order. It is better, therefore, to group them under two headings: (*a*) his deeds in private life; (*b*) his deeds in public life.

Under the first class, we may put (1) the healing of the waters of Jericho (2 Kings ii. 19–22); (2) the punishment of the lads of Bethel (2 Kings ii. 23–25); (3) the saving of a widow's son from slavery (2 Kings iv. 1–7); (4) the restoring of the Shunammite's son to life (2 Kings iv. 32–36); (5) the rendering of some poisonous pottage harmless (2 Kings iv. 38–41); (6) the miraculous feeding of a hundred men (2 Kings iv. 42–44); (7) the healing of Naaman the leper (2 Kings v.); (8) the causing of the iron head of an axe to swim (2 Kings vi. 1–7).

Under the second class we may put (1) his helpful work in the campaign against Moab (2 Kings iii. 11–24); (2) his bringing of the Syrian army into Samaria, where they were made prisoners (2 Kings vi. 8–23); (3) his activity in the siege of Samaria (2 Kings vi. 24, vii. 2); (4) his visit to Damascus to announce to Hazael that he shall be king of Syria (2 Kings viii. 7–13); (5) the sending of a messenger to anoint Jehu to be king of Israel (2 Kings ix. 1–3); (6) the assuring of King Joash that Israel should be victorious over Syria (2 Kings xiii. 14–19).

But the power of Elisha for good did not end with his life. Of him alone of all the prophets it is recorded that he wrought a miracle after his death. A dead man who was hastily cast into the sepulchre of the prophet, on touching the prophet's bones, came to life, and stood upon his feet (2 Kings xiii. 20–21).

Consult: Grove, article 'Elisha' in Smith's 'Dictionary of the Bible' (1868); Strachan, article 'Elisha' in Hastings' 'Dictionary of the Bible' (1899); Farrar, 'Second Book of Kings,' chaps. iii.–xvii., in the 'Expositor's Bible' (1902).

SYLVESTER BURNHAM.
Professor of Old Testament Interpretation, Theological Seminary of Colgate University.

Elixirs, in pharmacy, are aromatic, sweetish, spirituous preparations, containing small quantities of active medicinal drugs. They are now mostly used as vehicles, and have very little potent action save that of the alcohol which they contain. Elixir aromaticum and Elixir phosphorus are the only two elixirs sanctioned by the 1890 revision of the United States Pharmacopœia.

Elizabeth, the wife of Zacharias and mother of John the Baptist. An angel foretold to her husband the birth of a son to her old age; and it was also foretold by the angel Gabriel to the Virgin Mary, as an assurance of the birth of the Messiah.

Elizabeth, Saint, of Hungary, daughter of Andrew II., king of Hungary, and Gertrude, daughter of the Duke of Carinthia: b. Presburg 1207; d. Marburg 19 Nov. 1231. Early in life she displayed a dislike for things worldly, as the pomp with which she was surrounded, ambition, avarice, and vain pleasures, and began to cultivate humility, piety, and great charity. According to the custom of the times, when she was only four years old she was betrothed by her parents to Louis, the son of the landgrave of Thuringia, who was about her own age. When Elizabeth was 14 years old they were married. Her husband admired his wife's piety and approved her great charity, especially during the famine in Germany in 1225, although members of his own family severely censured her. She founded hospitals in Marburg and other places within her husband's dominion. (Louis' father died the year after the betrothal, and he was the landgrave when he married Elizabeth.)

In 1227 Louis left home with Frederick Barbarossa to engage in the war for Palestine; but before reaching the Holy Land Louis died from fever. Great misfortunes soon befell Elizabeth. She was deprived of her regency by the brother of her deceased husband, and driven out of her dominion on the plea that she wasted the treasures of the state by her charities. The inhabitants of Marburg, whose miseries she had frequently relieved, refused her any asylum, for fear of the new regent. At last she found refuge in the monastery of Kitzingen, where her aunt was abbess, and later with her uncle, bishop of Bamberg, and when the warriors who had attended her husband in the Crusade returned from the East with his body, she gathered them around her, and recounted her sufferings and the wrongs done to her three children. Steps were taken to restore to her her sovereign rights. She declined the regency, however, and would accept only the revenues which accrued to her as landgravine. The remainder of her days were devoted to almsgiving, mortifications, and prayer. She became a member of the Third Order of Saint Francis, and in pictures she is often represented clothed in the Franciscan habit. She was canonized by Gregory IX. four years after her death. Consult: Montalembert, 'Life of Saint Elizabeth of Hungary'; Starr, 'Patron Saints'; Butler, 'Lives of Saints'; Bonaventure, 'Sermon on St. Elizabeth'; Theodoric, and Montague of Spire. There are extant manuscripts on her life, by contemporaries, Conrad of Marburg, Siegfried of Mentz, and others.

Elizabeth, queen of England: b. Greenwich 7 Sept. 1533; d. Richmond, Surrey, 24 March 1603. She was the daughter of Henry VIII. and of Anne Boleyn. After her mother had been beheaded (1536) both she and her sister Mary were declared bastards, but finally she was placed after Prince Edward and the Lady Mary in the order of succession. Thus, while the first two marriages of King Henry were both still held to be illegal, the children of both were legitimized. Elizabeth received a classical education, as was customary with women of rank in her time, and under her tutor, Roger Ascham, is said to have attained very considerable proficiency in Latin and Greek. During her father's life, as well as in the reign of her brother, various negotiations were entered into for her marriage. The Duke of d'Angoulême and Philip of Spain, who afterward married her sister, were among the matches proposed for her; but the only affair of this kind in which she may be supposed to have been personally interested was the suit of Lord Seymour of Dudley, the Protector Somerset's brother. It is certain that even during the life of Catharine Parr, the widow of Henry VIII., whom he married, his attentions to the Lady Elizabeth were only too well encouraged. Both before this marriage and after the death of his wife he was a suitor for the hand of the princess; but his ambitious designs in this and other matters were not countenanced by the council, and ultimately cost him his life.

On the death of King Edward Elizabeth vigorously supported the title of Queen Mary against the pretensions of Lady Jane Grey, by which her own title as well as her sister's were barred. She rode to meet her sister, accompanied by 1,000 horse, and this bold proceeding was of no small service in confirming the doubtful in their allegiance; but Elizabeth gained little for herself by a policy in which it was well understood she had her own interest in view. After Wyatt's conspiracy her life was in great danger, and was probably saved only by the intercession of Philip. She was committed to the Tower, from whence she was removed to Woodstock, where she was confined with great strictness. She afterward, through Philip's intercession, obtained greater liberty; but throughout the whole reign continued an object of suspicion and surveillance. The danger she now incurred developed a trait in her character which ever after continued conspicuous, her power of dissimulation. She made every demonstration not only of conformity, but of zealous adherence to the established religion. Her conduct in this must not be judged from the point of view of rigid Protestantism, which Elizabeth never professed; but there were some at least among the

Roman Catholic ceremonies and customs to which she could not be supposed to give a sincere adherence. Nevertheless, her false zeal must have been well and ably sustained, for her conduct was not left to the report of friends, but carefully watched by spies and informers. Philip was most anxious to have her married out of the kingdom; and if the Duke of Savoy, whom he proposed, was unacceptable from his Roman Catholicism, there was Eric, son of the king of Sweden, who long after continued to press his suit; but Elizabeth refused both. She felt in herself a capacity for rule, and her sister's ill health opened up for her an early prospect of the throne, which she was unwilling to peril. Mary's reign was not without advantage to Elizabeth. It tried her councilors as well as herself, and gave her the opportunity of selecting them to advantage. Her adviser throughout the whole of it was William Cecil, afterward Lord Burleigh, who had already been a minister under Edward VI., and continued for the rest of his life to be one of the chief councilors and ablest ministers of Elizabeth, to whom he was in many respects a congenial spirit.

On 17 Nov. 1558 Mary's disastrous reign came to a close, and Elizabeth was immediately recognized queen by Parliament. On entering London she was met by the bishops, whom she permitted to kiss her hand, with the exception of Bonner, "whom she omitted for sundry severities in the time of his authority." It was now that the caution and secrecy characteristic equally of Elizabeth and Cecil, and which enabled them to do such great things, appeared in spontaneous exercise. The Roman Catholic religion was still predominant in the House of Lords, and any attempt to overthrow it suddenly might have been attended with the greatest danger. Elizabeth made no immediate change in her habits. For a full month the ceremonies of the Roman Catholic Church were retained in all their state. A solemn funeral service was held for Queen Mary in Westminster Abbey, at her interment on 13 December. The queen even intimated her accession to the Pope. She retained the greater part of her sister's council, choosing only seven new councilors, who were Protestants, it is true, but not then known as such. Like Cecil and herself, they had all conformed, and possessed the necessary qualification for Elizabethan councilors of accomplished hypocrisy. Such were her difficulties, notwithstanding her great prudence, that at her coronation only one of all the bishops, Oglethorpe of Carlisle, could be found to set the crown on her head. The obstacle, it is said, was her refusal to permit the elevation of the host. She had also before this authorized the reading of the liturgy in English. The first great object of her reign was the settlement of religion. A Parliament was immediately called, to which this work was assigned. It met on 25 January, and was dissolved 8 May, but its object was already accomplished. The nation was prepared for a return to the reformed faith, and the Parliament was at the bidding of the court. The reformation of religion in England was the work of Cranmer, and had already been accomplished in the reign of Edward VI.; the reestablishment of the ecclesiastical system of the national Church on the basis on which it has remained to the present day was the work of Cecil and Elizabeth, and it was nearly completed in this Parliament. Elizabeth had less extreme opinions than many supporters of the new faith. She was tolerant, for instance, in regard to images, and is said to have entertained scruples as to the extent of the royal supremacy in spiritual matters; but if she did, they must have been purely speculative. They certainly vanished on the first taste of power.

If the formal establishment of the reformed religion was easily completed, the security and defense of the settlement was the main object of the policy and the chief source of all the struggles and contentions of her reign. What made the position so difficult was the intolerance by which at this period and for long after all religious sects were characterized. No sooner were the Puritans freed from the restrictive measures of Mary's reign than they began to claim predominance for their own dogmas. But it was far from the intention of the queen and the supporters of the Established Church, notwithstanding the common persecutions they had endured, to grant them even liberty of worship. Elizabeth's own determination, as expressed by herself, was that none should be allowed to turn aside either to the right hand or the left from the drawn line of prescribed duty, and in insisting upon uniformity of worship she was not singular, but was acting in the spirit of her age. This principle was not less firmly held in her reign than in her sister's; and Roman Catholics on the one hand, and Puritans on the other, restrained only by their dread and hatred of each other, were made the irreconcilable enemies of the existing order. Moreover, from the necessities of the struggle the severities of Elizabeth's reign went on increasing as time advanced. At first no one suffered death for his opinions; but eventually many were executed for this cause. The struggle against Roman Catholics was the most severe, chiefly because they were supported by foreign powers; so that while their religion was wholly prohibited, even exile was forbidden them in order to prevent their intrigues abroad. Simple non-conformity, from whatever cause, was pursued with the severest penalties. The fine imposed for non-attendance at church was £20 per month, while so strait were the lines of conformity drawn, that many more clergymen were driven out of the Church by differences about the position of altars, the wearing of caps, and such like matters, than were forced to resign by the change from Rome to Reformation. These stringent measures were, however, the rigid consequences of the false position assumed.

Elizabeth's first Parliament approached her on a subject which, next to religion, was the chief trouble of her reign, the succession to the crown; they requested her to marry. She replied in a long speech, declaring her intention to live and die a virgin. It is certain, from her conduct both before and after, that this declaration was only a convenient affectation of prudery, which at once served to flatter her vanity and to veil her real indecision. She saw too clearly for her own interest the restraints to which each particular marriage might subject her, and therefore, she shunned them all, thus leaving open the question of the succession.

On Elizabeth's accession the country was at war with France. Peace was easily concluded

1559; but the assumption by Francis and Mary of the royal arms and titles of England led to an immediate interference on the part of Elizabeth in the affairs of Scotland. She entered into a league with the Lords of the Congregation, or leaders of the Reformed party; and throughout her reign this party became distinctively an English one, and was frequently serviceable in furthering her policy. She also gave early support to the Huguenot party in France, and to the Protestants in the Netherlands, so that throughout Europe she was looked on as the head of the Protestant party. This policy roused the implacable resentment of Philip, who strove in turn to excite the Roman Catholics against her, both in her own dominions and in Scotland. After the detention of Mary queen of Scots in England, he fomented the various rebellions in her favor formed in England and Ireland, and at her death declared himself her avenger. Mary, as is well known, was imprisoned 19 years in England, whither she fled to the protection of Elizabeth. Her imprisonment was followed by a series of conspiracies, beginning with that under the earls of Northumberland and Westmoreland, and ending with the plot of Babington, which finally determined Elizabeth to make away with her captive. The execution of Queen Mary was, nevertheless, the chief political blunder of Elizabeth's reign. If the death of Mary did not raise up new enemies to Elizabeth on the continent it at least gave a just cause of scandal to those she already had. Elizabeth had for some time been engaged in a negotiation for marriage with the Duke of d'Alençon (afterward d'Anjou); and in 1580 the Duke arrived in London to pursue his suit, which had lasted nearly 10 years, in person. He was well received, but still the queen hesitated. She was now 47. The following winter the Duke paid another visit, and the marriage was all but concluded, but she finally informed him she could never marry.

The state of France, as indicated by the change of government consequent on the accession of Henry IV., who was assisted by Elizabeth, obviated any danger that might have arisen from the indignation which the execution of Queen Mary had caused in that country. Nowhere, however, was that event more meekly borne than by King James. The Scottish Solomon had thought his mother's danger a favorable opportunity for sententious observations about the strangeness of her case, and now his philosophy was nonplussed. His awe of Elizabeth and his dread of interfering with his own right of succession to England made him powerless, and he accepted an addition to his pension in full of all grievances. Philip was not to be so appeased. He had other grievances, to which the execution of Mary lent edge. The fleets of Elizabeth had galled him in the West Indies, her arms and subsidies had helped to deprive him of the Netherlands; the Armada was already in preparation. Therefore he called the queen of England a murderess, and refused to be satisfied even with the sacrifice she seemed prepared to make of her Dutch allies. The Armada sailed on 29 May 1588. Its fate is too well known to need recapitulation. The war with Spain dragged on till the close of Elizabeth's reign.

During her long rule Elizabeth showed her judgment in nothing so much as in the councilors she trusted. But while the splendor of her government at home and abroad was sustained by such men as Burleigh, Bacon, Walsingham, Throgmorton, and Davison, who served her with a zeal which did not always spare even their own reputations, she had personal favorites of less merit who were often more brilliantly rewarded. It is sufficient to name Dudley, whom she created Earl of Leicester; and Essex, who was still more a personal favorite, though much less a courtier. The latter had some merit as a soldier; but his violent temper, ill-suited to the queen's haughty disposition, brought about his ruin. He was beheaded in 1601, and Elizabeth never forgave herself his death. Her own health soon after gave way, and she died, naming James of Scotland as her successor.

Besides its political glories, the reign of Elizabeth was the golden age of English literature. If all else could be forgotten, it would be remembered as the age of Spenser and of Shakespeare, not to mention a host of minor names. The naval achievements of Drake and the discoveries of Raleigh concurred to do it honor. Thus everything conspired to throw a halo round the name of Elizabeth, when regarded as a sovereign, and seen as she would be in her own day, especially by foreign beholders, through the drapery of state. If a minute criticism has exposed some of the weakness of the individual woman who bore this burden, it must be remembered that the process is only half fair. As a sovereign she is entitled to her surroundings, and as an absolute ruler, as to a great extent she undoubtedly was, she must have her share of praise for the good that was done in her name. It is no small merit to select good councilors and to adhere to them. Elizabeth knew how to do both; and yet she was no puppet in the hands of her advisers. Though haughty and imperious to the Commons, she knew both when and how to yield. She studied with rare sagacity the temper of the people; and high as were her notions of prerogative, she may fairly be considered the first constitutional monarch of England.

Elizabeth, empress of Austria: b. Possenhofen, Bavaria, 24 Dec. 1837; d. Geneva 10 Sept. 1898. She was the daughter of Duke Maximilian Josef of Bavaria, and married her cousin, the Emperor Franz Josef on 24 April 1854. Together they were crowned with the insignia of St. Stephen when the inauguration of the dual system was solemnized. She was greatly admired by Austrians and Hungarians alike.

While visiting Geneva, Switzerland, she was assassinated by an Italian anarchist.

Elizabeth Farnese, fär-nā'zĕ, queen of Spain: b. 25 Oct. 1692; d. 1766. She was a daughter of Edward II., Prince of Parma. On becoming the second wife of Philip V. she surprised those who had counseled the marriage by assuming the practical headship of the kingdom; her ambition and that of her minister, Alberoni, disturbed the whole of Europe.

Elizabeth, Madame (ELISABETH PHILIPPINE MARIE HÉLÈNE), French princess: b. Versailles 3 May 1764; d. Paris 10 May 1794. She was a sister of Louis XVI. She was the faithful friend and companion of the royal family in their flight to Varennes, and during their imprisonment was executed, on the pretense of corresponding with her other brothers, afterward Louis XVIII. and Charles X.

Elizabeth, Pauline Ottilie Luise, queen of Rumania (pseudonym «CARMEN SYLVA»): b. Neuwied 29 Dec. 1843. She married Charles of Rumania, 15 Nov. 1869. She is well known as a writer over the signature «CARMEN SYLVA,» her works including ‹Sappho› (1880); ‹Hammerstein› (1880); ‹Stürme› (1881); ‹Leidens Erdengang› (‹Sorrow on Earth›) (1882); ‹Les pensées d'une reine› (1882); ‹Pelesch Märchen› (1883); ‹Le pic aux regrets› (1884); ‹Es klopft› (1887); etc.

Elizabeth Petrow'na, empress of Russia: b. 29 Dec. 1709; d. 5 Jan. 1762. She was the daughter of Peter the Great and Catharine, and ascended the throne on 7 Dec. 1741, as the result of a conspiracy, in which Ivan VI., a minor, who had reigned only one year, was deposed. Elizabeth is said to have rivaled her mother in beauty, and to have surpassed her in her love of pleasure. Her reign was stained both by her unbridled licentiousness and the tyranny of her government, which was conducted by favorites. Banishment to the mines of Siberia and imprisonment in dungeons were awarded for the slightest political offenses. She was a patron of literature, and corresponded with Voltaire, to whom she supplied materials for his ‹Life of Peter the Great.› She also founded the University of Moscow and the Academy of Fine Arts of St. Petersburg. Elizabeth sent an army, in 1748, to assist Maria Theresa in the war of the Succession, which contributed to bring about the Peace of Aix-la-Chapelle; and she joined in the Seven Years' war against Prussia.

Elizabeth Stuart, queen of Bohemia: b. Falkland Palace, Fifeshire, 16 Aug. 1596; d. London 13 Feb. 1662. She was a daughter of James I. of England, and was married to the Palatine Frederick at Whitehall, 14 Feb. 1613. Her husband was then at the head of the Protestant interest in Germany, and in 1619 he accepted the crown of Bohemia offered to him by the revolted Protestants of that country. This he was only able to retain for a very short period; and after his defeat by the Imperialists at the battle of Prague in 1620, he and his wife were obliged to flee, first to Breslau and Berlin, and then to The Hague. Elizabeth had 13 children, several of whom died early. Charles Louis, the eldest surviving, was reinstated in the palatinate by the Treaty of Westphalia in 1648. His daughter, Elizabeth Charlotte, was the second wife of Philip, Duke of Orleans, brother of Louis XIV. Her descendants were excluded by their Catholicism from the crown of England, but one of them was regent of France during the minority of Louis XV.; and another, Louis Philippe, ascended the throne after the revolution of 1830. Her sons, Princes Rupert and Maurice, distinguished themselves in the civil war in England. Her daughter, Sophia, married into the house of Brunswick, became electress of Hanover, and mother of George I. Elizabeth Stuart's cause was extremely popular with the English nation, and after her husband was deprived of the crown of Bohemia she still retained among them the endearing epithet of «Queen of Hearts.» She returned to England at the Restoration with her nephew, Charles II.

Elizabeth of Valois, vä-lwä, or **Isabella,** Queen of Spain: b. Fontainebleau, France, 22 Nov. 1545; d. Madrid 3 Oct. 1568. She was a daughter of Henry II., of France, and Catharine de Medici. She was destined to be the wife of the infante, Don Carlos, but his father, Philip II., being left a widower, became fascinated and married her himself. The story of a romantic relationship between Elizabeth and Don Carlos has furnished tragic subjects to Otway, Campistron, Chénier, Schiller, and Alfieri.

Elizabeth, Cape. See CAPE ELIZABETH.

Elizabeth, N. J., city, county-seat of Union County; on Newark Bay and the Arthur Kill; and on the Pennsylvania, Lehigh Valley, Baltimore & O., Philadelphia & R., and New Jersey C. R.R.'s; 14 miles southwest of New York. The chief articles manufactured are sewing-machines (one of the shops of the Singer Manufacturing Company employing about 10,000 people being located here), oilcloth, hats, saws, mill-machinery, stoves, hardware, edge-tools, harness, cordage, and combs. A large business is done in the shipment of anthracite coal. The shops of the Central Railroad, employing about 1,000 hands, and the Crescent Steel Works and shipyard are located here. There are three banks, one savings bank and a trust company with a combined capitalization of $700,000 and deposits of $7,154,000, and building and loan associations. Among public institutions are the Alexian Brothers Hospital, General Hospital, Saint Elizabeth Hospital, Orphan Asylum, Old Ladies Home, and Public Library. The educational institutions include the Battin and Pingry high schools, the Vail-Deane School, a business college, and 11 public schools. The city has electric lights and street railways, many handsome churches, and contains an old tavern where Washington stopped on his way to New York for his inauguration. Gen. Winfield Scott's home, the Boudinot House and the old Livingston Mansion. It was settled in 1664 as Elizabethtown and was the state capital from 1755 to 1757. It became a borough in 1748 and was incorporated as a city in 1855. The present form of government is by mayor and council of 24 members elected for two years. Pop. (1900) 52,130.

Elizabeth City, N. C., town, county-seat of Pasquotank County; on the Pasquotank River, and the Norfolk & S. R.R.; about 145 miles northeast of Raleigh. A State normal school is located here. The region about is adapted for agriculture, lumbering, and cotton raising. The manufactures of the town are varied, including cotton, flouring-, saw-, and planing-mills, ship-building, and brick yards, carriage and wagon factories. The town was founded in 1793, and now has a government consisting of a mayor and a municipal council. A naval victory was gained here by the Federals under Commodore Rowan, 10 Feb. 1862. Pop. 6,500.

Elizabeth Islands, a Massachusetts group, 16 in number, forming the town of Gosnold, in Dukes County. They are situated between Vineyard Sound and Buzzard Bay; area, 14 square miles. In 1602 the first New England settlement was made on one of these islands, Cuttyhunk, by Bartholomew Gosnold; but after a residence of a few weeks it was abandoned, and Gosnold returned to England (see GOSNOLD, BARTHOLOMEW). The islands are now favorite summer resorts. Pop. 164.

Elizabethan Architecture, a style of architecture, which began to prevail in England during the reigns of Elizabeth and James I. It was a mixture of inferior Gothic with debased Italian, often very picturesque, but without purity and unity of design. It was characterized by deeply embayed windows, galleries of great length, very tall and elaborate chimneys, strap work in the parapets and window-heads, and many dormented details of surface-carving characteristic of the bizarre influence of the combined Renaissance forms from Germany and Holland. The names of Holbein and John of Padua are associated with this style of architecture in which they had hoped to revive classic models. The mansions erected for the nobility during the reigns of Elizabeth and James I. are examples of this style of architecture, particularly the palace erected in the mixed style for Protector Somerset by John of Padua and the mansion of Longleat for his secretary Sir John Thynne. Others which may still be seen near London and which represent the architecture of the 17th century are: Knowle, belonging to the Duke of Dorset, the Marquis of Salisbury's at Hatfield, Holland House, Campden House in Surrey, Bramshill in Kent, Sir T. Willow's at Charlton, Burton Agnes, Blicking, Montacute, Audley End, Mogus Park, Aston, etc. This style was succeeded by the Jacobean in which Gothic details disappeared. Consult Gosch and Brown, 'Architecture of the Renaissance in England' (London 1894); Richardson, 'Architectural Remains of the Reigns of Elizabeth and James I.' (London 1840); Blomfield, 'History of Renaissance Architecture in England' (London 1897).

Elizabethan Literature.—The Drama. At the beginning of the reign of Elizabeth the conflict between mediævalism and humanism was rife in the drama as in other forms of literature. For the preceding half century there had been a confusion of types; miracle, morality, interlude, and farce existing side by side and exhibiting various differentiations, and there had been a confusion of theatrical conditions, play-acting still remaining largely in amateur hands. Neo-latin imitations of the classics were being succeeded by academic attempts in the vernacular. 'Ralph Roister Doister,' written by Nicholas Udall for a school performance had already in 1552 marked the appearance of comedy as a distinct form after the Plautian model; and 'Gorboduc,' by Sackville and Norton, performed in 1562 before the queen, was the first vernacular tragedy. Two other extant plays written within the next few years and performed by amateurs, 'Jocasta' and 'Tancred and Gismunda,' were, like 'Gorboduc,' attempts by Englishmen of culture to imitate the tragedies of Seneca in accord with the practice of Italian humanists. Meantime 'Apius and Virginia' and 'Damon and Pithias,' mixtures of tragedy and comedy, exhibited the persistence of popular methods combined with classical borrowings, while 'Cambyses' and 'Horestes' were formless chronicles of atrocities without any perceptible classical decorum. The building of the first London theatre in 1576 was the sign of the speedy triumph of the professional companies as the chief purveyors of the drama. A dozen years later the advent of a group of gifted poets prepared the way for Shakespeare by determining the course of a popular drama that was to be literary though disregardful of classical restrictions.

Comedy, where the departure from mediæval forms required by the humanists was far less than in tragedy, was the first to attract literary talent to the public stage. The plays of Wilson revealed a satirical comedy of manners emerging from the morality, and the entertainments devised by Lyly for the children companies, combined lyrical and spectacular attractions with a refined wit and a certain graceful courtliness. Later Green introduced sentimental comedy with its averted tragedy and its idealization of women. Such hasty summarizing, however, does scant justice to the variety and ingenuity of the experiments that preceded Shakespeare, drawing their material from every field from classical myth to native folk lore, and essaying and amalgamating every department of comedy from the Plautian to the pastoral. Most characteristic, perhaps, of all was romantic comedy, usually based on Italian *novelle* and offering a medley of fun, sentiment, and adventure.

In tragedy Kyd adapted Seneca to the conditions of the popular theatres, discarding most of his structural scheme but retaining the story of revenge, the accompanying ghost, the horrors and the moralizing; and thus in the 'Spanish Tragedy' (c. 1587), creating a special type destined to a vigorous existence. Marlowe (1564-93) turned his back on Senecan methods and brought to the rambling and discordant structure of the current popular history plays his splendid blank verse and his soaring imagination. 'Tamburlaine,' 'Faustus,' the 'Jew of Malta,' and 'Edward II.,' the chief plays of his half dozen years of dramatic activity, delighted the vulgar by their violence and spectacle, and at the same time made the public stage the abode of noble noetry and genuine passion. His genius, though never fully developed, remade tragedy and history, giving to the chronicle structure the unity of a protagonist, possessed by extraordinary ambition and engaged in tragic conflict with overpowering opposition.

In Marlowe, as in the other early Elizabethans, there is much that is fantastic, crude, and absurd. The primary aim of each dramatist was to present a story so as to delight a motley audience; hence the tendency was naturally toward stories of sensational crimes for tragedy and of romantic adventures for comedy, without much care for the isolation of either species. Like Marlowe, however, the other dramatists were poets as well as playwrights, stimulated by that imaginative idealism so nobly characteristic of the national temper in the years of Elizabeth's greatness, and in their exuberant and somewhat over fantastic verse reflecting the audacity, adventurousness, emotional extravagance, and undaunted aspiration of the age.

Shakespeare's apprenticeship was served in this period, and his early plays naturally follow the forms then current and exhibit the qualities most prominent in other dramatists. The 'Comedy of Errors' is an adaptation of Plautus; 'Love's Labours Lost' follows Lyly; the 'Two Gentlemen of Verona' recalls the sentimental comedy of Greene; 'Titus Andronicus' is a melodrama of atrocities after the fashion of Kyd; 'Henry VI.' is dominated by Marlowe; and 'Richard III.,' following the Marlowean formula, surpasses the master in the vigorous delineation of the villain protagonist and in the stage effectiveness of his part. But Shakespeare soon left his fellows far behind. The 'Midsummer Night's Dream' and the 'Merchant of Venice' transcended the romantic comedies that had made them possible on the London stage, and 'Romeo and Juliet' as completely surpassed the prevailing tragedy of blood. By 1600 Shakespeare had created his great series of comedies and in the Falstaff plays had wrought a union of comedy and history such as the early chronicle plays had only dimly foreshadowed.

By 1600 new forces were manifest in the drama. A young poet, Marston, was following his successful satires by a series of plays, in part tragedies of blood on the Kydian model, and in part satirical tragi-comedies, which aimed to be searching studies of evil. In 1599 Ben Jonson's 'Every Man in His Humour,' acted by Shakespeare's company, was prefaced with a declaration of war on the absurdities of chronicle history and romantic plays, and with the promise of the creation of a comedy dealing with contemporary manners. Jonson, indeed, continued a powerful force in the drama for the next 25 years. His preaching was all directed toward the establishment of a more conscious and painstaking art, and its regularization by classical examples, while his practice resulted in a noteworthy series of satirical comedies, presenting with powerful humor and realism the follies and vices of the day. Chapman and Middleton were also writing comedies of domestic manners, and the whole trend of the drama from 1600 to 1608 was away from romance and sentiment, resulting in a satirical and realistic treatment in comedy and a more searching analysis of evil in tragedy. Under these circumstances Shakespeare's great series of tragedies was produced. This is not the place to speak of their lasting significance, but merely to note that his genius, now in the full maturity of its powers, was still engaged in transforming the prevailing types of drama. Narratives from chronicle and *novella,* so often the sources of formlessness of structure, resulted in the splendid dramatic concentration of 'Macbeth' and 'Othello'; the absurd tragedy of blood, popular again through the efforts of Marston and others, became 'Hamlet' with its infinite suggestiveness of human tragedy; the grotesqueness characteristic of mediæval as well as Elizabethan drama had its final justification in 'Lear.'

By 1607-8 the success of the heroic plays of Beaumont and Fletcher had brought the romantic and idyllic again into favor and perhaps given the suggestion for Shakespeare's return to romantic tragi-comedy in 'Cymbeline,' a 'Winter's Tale,' and the 'Tempest.' Heroic romances, such as 'Philaster' and the 'Maid's Tragedy' succeeded not only because of their poetry and their sensational contrast of sentimental love and sensual passion, but even more because of the telling theatrical effectiveness of their situations and the clever alternations of suspense and surprise with which their ingenious plots were complicated. The comedy of Beaumont and Fletcher, especially in its later development by Fletcher, like their heroic plays, had a long continued influence on the drama. Possessing ready wit, great poetic facility, and an abundant invention, but without moral taste or any serious criticism of life, Fletcher marks a stage in the drama that may fairly be called decadent when we recall the sound moral sense and the artistic aspiration of the early plays. Yet the last decade of Shakespeare's life was the time of Jonson's greatest comedies, of the masterpieces of Beaumont and Fletcher, and of some of the best work of Chapman, Tourneur, Webster, and Middleton.

The very existence of these masterpieces was of itself a factor in the drama's decline. Webster, writing in 1612, made the first avowal of obligations to his great contemporaries; and henceforth the increasing recognition of the greatness of the immediate past seemed to stifle rather than to inspire innovation and experiment. Webster himself, borrowing freely from others, carried the tragedy of blood to its final development in the powerful and gloomy 'White Devil' and 'Duchess of Malfi.' Middleton in collaboration with Rowley created scenes of powerful tragic interest in 'A Fair Quarrel' and the 'Changeling.' Massinger, collaborating often with Fletcher and to a considerable extent borrowing Fletcher's methods, produced a body of tragedy and tragic-comedy, morally didactic, and rhetorically excellent, but in characterization and poetry somewhat deficient. These are only a few of the writers of tragedy during the reign of James I.; in the development of comedy, where less poetical excellence is demanded, the number of important contributors was much larger. Middleton's most characteristic work was a group of lively comedies that exposed contemporary manners with the frankest realism. Massinger, though on the whole deficient in humor, produced in 'A New Way to Pay Old Debts' the noteworthy character of Sir Giles Overreach that has attracted many great actors, including Kean. Dekker and Heywood, writers without great literary pretensions, wrote a large number of successful plays. Dekker ranged from the romantic idealism of 'Old

Fortunatus' and the sentiment and merriment of the 'Shoemaker's Holiday' to the painful realism of the 'Honest Whore.' Heywood, always a skilful and inventive playwright, likewise wrote plays of every kind, achieving a real masterpiece in his 'A Woman Killed with Kindness' This play may be classed as a sentimental tragic-comedy or as a domestic tragedy, a class which includes a number of plays depicting current crimes and goes back at least as far as 'Arden of Feversham' in Marlowe's day. One other dramatic form, extremely popular in the court of James I., must be mentioned, the court mask. For these scenic and musical entertainments many dramatists, and notably Jonson, wrote libretti; and the spectacles and dances in turn had an important influence on the popular theatres. The dramatic product of the reign of James I. (1603-1625) was indeed fully as large as that of the reign of Elizabeth, and, including as it did the last nine years of Shakespeare's career, vastly greater in value. But the enthusiasm and earnestness of the days of the Armada were succeeded by a time of immorality, corruption, and national weakness. The people were turning more and more to Puritanism, but the drama, following the court, grew less serious, more licentious, and gradually forgetful of its high calling.

During the reign of Charles I. the drama offered little that remains notable, outside of the continued work of the older writers and the plays of Ford and Shirley. Ford, a poet of original and lofty genius, ranks with the great dramatists in the intensity of his tragic crises, but he sought themes and motives, abnormal and decadent. The great dramatists of the preceding generation stimulated Shirley, who was their last worthy follower and who often recalls but never quite equals their best work. Of comic dramatists Brome, of "the tribe of Ben," and Davenant, who belongs to the Restoration, are possibly the most noteworthy. But the great majority of the many plays produced were mediocre. The drama no longer represented the nation; nor in the approach of the civil conflict could it longer command the interest and energy of great intellects or imaginations. It had little virility left when the Puritans closed the theatres in 1642.

Within a few years Chapman, Dekker, and Jonson, the last surviving dramatists of Elizabeth's time, had died. Their lives had spanned the entire course of the drama's development, its rapid rise, and its splendid culmination as well as its decline. The 30 years from Marlowe's first play to the death of Shakespeare include, in fact, all that is great in this amazingly rapid development. Incomparable as this period is because it contains the career of Shakespeare, it is hardly less astonishing because of the variety and range of the work of his fellows. Lacking, as even Shakespeare's plays lack, in the symmetry and unity of the Athenian drama; faulty, as his plays are often faulty, in the over exuberance of language and the violence and extravagance of scenes; suffering, as his genius suffered, from the crudity of a bare stage and an immature dramaturgy; these Elizabethan plays, taken as a whole, reveal, in however inferior measure, his great excellences, the untrammeled play of wit, sentiment, fun, and fancy; a splendid energy of diction and of dramatic treatment; a searching revelation of human character, and an abounding grace and power of poetic expression. See DRAMA.

A. H. THORNDIKE,
Professor of English, Columbia University.

Elizabethan Literature — Non-Dramatic Poetry. Elizabethan poetry is the product of the Renaissance,—the flowering of the English stock under the fertilizing power of European thought. English literature at all points—in Alfred's time, in Elizabeth's, in the 18th and 19th centuries,—has owed its great moments to foreign inspiration, but this is true of no age so conspicuously as of the Elizabethan. The period is short, if it be measured strictly by Elizabeth's reign, 1558-1603; and even if the limits be broadened to include Wyatt and Surrey at the beginning and all of Shakespeare's work at the end, it is still but narrow room for the development of the crude religious play into the drama of Shakespeare and Jonson,—of the clumsy sonnets of Wyatt into the great sequences of Sidney, Spenser, and Shakespeare,—of the stiff Tudor music into the noble harmonies of the madrigals and the sweet melodies of the airs.

Perhaps because of this swiftness of development, the age illustrates with unusual clearness the transference of life to books. The rush of genius draws into its vortex most of the experience about it; Spenser's friends enter the 'Faërie Queene' unchanged, and in spite of the allegory, undisguised; Sidney's passion takes over the incidents of his wooing with an immediateness that the occasional bookishness of his inspiration cannot smother; history, scarce made, is subject for a play; the gossip of a ship-wreck becomes the 'Tempest'; and—perhaps most interesting of all—those first poets themselves, the type of the age, Surrey, Sidney, Greville, Raleigh, are caught up as they drop from life, and continue immortal in Shakespeare's young men—Biron, Valentine, Romeo. The contrast here suggested between the mass and power of its literary inheritance and the directness of its foundation upon life, is the distinction of Elizabethan poetry, and perhaps the source of most of its problems.

In this swift drawing-in of Continental Renaissance thought with English history and character, the age is set off by three great names—Spenser, Shakespeare, and Milton—for though Milton stands well outside the Elizabethan period, he is the last term in its development. The apparent remoteness of Spenser, his un-English quality, is due probably to the fact that he is nearest to the great wave; he takes over a larger quantity of unnaturalized material; he represents the early school of wholesale colonizers of Italian thought on English soil. Yet he takes over into his writings quite as much of English life, even of English incident, and quite as much of English character, as Shakespeare. The great dramatist, at first glance so natural, so near to his race, so untouched by the tyranny of books, is indeed all these things, yet his imagination starts always in some foreign suggestion. Aside from the different scale of genius, he is as English as Spenser—no more so; but he represents a more complete blend of the foreign themes with the native mind. So

Milton also, heir to the assimilated learning of the Renaissance — to humanism, yet draws on the most English sources of life — English experience, English character, English landscape. These three poets illustrate the Elizabethan age in that they are typically individual, typically English, and typically children of the Renaissance mind.

It is usual to take as the beginning of Elizabethan poetry the book in which the Elizabethans themselves saw the herald of their day —'Tottel's Miscellany' (1557). This book, a publisher's venture, contained the work of several courtly poets, notably of Sir Thomas Wyatt (1503–1542) and of Henry Howard, Earl of Surrey (1516?–1547). Though the selections were written before Elizabeth's reign, they unfolded already the characteristics of the new age. The sonnets, modeled after Petrarch or translated from him, foretold the later sonnet fashion, with its heavy draughts upon the Italian spring; the imitations of classical poetry showed that the English writers had found the feeding root of the Renaissance itself; and the translations as a whole pointed in the direction of the more notable transferrings of the world's imagination to English, Golding's (1536?–1605) Ovid, 1567, and Chapman's (1559?–1634?) Iliad, 1598, and Odyssey, 1616. So also the lighter lyrics, the best of them by Wyatt, foretold the song-books; Surrey's sonnet to Clare and his poem on Windsor witnessed the vitality of the Elizabethan theme of friendship — the nearness of the living incident in his verse; and Grimald's (1519?–1561?) 'The Garden' prophecied at long range the love of English country life that was to find noble expression in Marvell and Walton.

The fame of Tottel's book made the miscellany a fashionable vehicle of publication throughout the Elizabethan age, though the growing habit of general publishing tended to diminish its importance. 'The Paradise of Dainty Devices' (1576), is interesting for the work it preserves of Richard Edwards (1523?–1566), of Edward de Vere, Earl of Oxford (1550–1604), and of Sidney's friend, Sir Edward Dyer (——?–1607), whose fine "my mind to me a kingdom is," appears in this anthology. 'A Gorgeous Gallery of Gallant Inventions' (1578), illustrates the fashion of translation, and bears witness, in the names of tunes for the poems, to the growing invasion of poetry by music. 'A Handful of Pleasant Delights' (1584), is a weaker anthology, of practically no merit, but 'The Phœnix Nest' (1593), is noteworthy for the elegies on Sidney — one by Sir Walter Raleigh (1552?–1618), and for other poems by Raleigh and Thomas Lodge (1558?–1625). 'England's Helicon' (1600) includes selections from Sidney, Spenser, Breton, Lodge, Peele, and Barnfield, the great writers of the first Elizabethan period, strongly marked by the pastoral vein; the book would be notable for one poem alone, Marlowe's "Come live with me and be my love." 'England's Parnassus' and 'Belvidere, or the Garden of the Muses' (1600), are mere collections of quotations; 'Davison's Poetical Rhapsody' (1602), is of little more importance, though its selections reflect the sonnet vogue. An earlier and more important book, 'The Passionate Pilgrim, by William Shakespeare' (1599) is clearly a miscellany, as only part of its contents, some songs from 'Love's Labour Lost' and some sonnets, are by Shakespeare.

In subject matter the earlier part of the Elizabethan age was pastoral, following the tone set by Sidney's 'Arcadia' (1590). This Elizabethan pastoral, literary, and artificial as in Sanazzarro and other Italian models, left its impress on the incidental songs in the prose romances. Sidney himself was the most zealous experimenter in classical metres, in the general attempt that Gabriel Harvey fostered, to bring English verse under the laws of Latin prosody. Green and Lodge, the great writers of prose romance after Sidney, were less pedantic in their lyrics, yet their songs have the idyllic method of the pastoral, the method of painting.

The best representative of this pastoral period is Edmund Spenser (q.v.). His first book, 'The Shepherd's Calendar' (1579), was an imitation of the Virginian eclogue, with the same bookish flavor — here increased by Edward Kirke's commentary — and with the same allegorical treatment of contemporaries and events under the pastoral mask; but with an English setting and with English ideals that stamp the book as native. In 'The Faërie Queene' (1590–1596) and the 'Amoretti' (1595), Spenser speaks also through the pastoral convention — that subduing of all things to loveliness, which is the mark of the world of the Sicilian Muses. The 'Faërie Queene' especially, as might be expected from its ancestry in the Italian romantic epics, has the irresponsibility of pastoral romance — the arbitrary management of the facts of life as if those facts themselves were a flexible language. The paradox of the Renaissance, of Elizabethan literature, is illustrated here on the largest scale, in the gorgeous, archaic language, the unreal, un-English world of the story on the one hand, and on the other the stern English fibre of the ground theme. This same blending of Italian imagery and expression with English spirituality is seen in the 'Epithalamion' (1595) and in the 'Prothalamion' and the 'Four Hymns' (1596).

The pastoral convention, moulded by Spenser, remained popular, though less characteristic, in the succeeding decades. Michael Drayton (1563–1631), remembered now for his splendid 'Battle of Agincourt' (1605), and for his great sonnet, 'Since There's no Help' (1619), wrote much in the Spenserian pastoral, as did William Browne (1591–1643). In another way also the pastoral habit of beauty was transferred to poems not strictly pastoral, such as Shakespeare's 'Venus and Adonis' (1593), 'Lucrece' (1594), and Marlowe's 'Hero and Leander' (before 1593), where the convention of old-world beauty blends with the Elizabethan zest for a story, evidenced more popularly in the broadside ballads. The tradition of narrative poetry was strong throughout the Tudor period, from the 'Mirror for Magistrates' (1559) to Drayton's 'Baron's Wars' (1603).

As the first period of Elizabethan poetry is pastoral, so the second period, roughly from 1590 to 1600, is marked by the sonnet fashion. The Italian sonnet had been introduced in detached imitations and translations by Wyatt and Surrey, but the fashion of sonnet sequences was set by Sir Philip Sidney's (1554-1586) 'Astrophel and Stella,' published in 1591, but known much earlier. Sidney here followed Petrarch, after the example of the innumerable French sonneteers. His sonnets, however, derive vital and individual interest from the circumstances of his own love for Penelope Devereux, a passion as famed among his contemporaries as Petrarch's love for Laura. His poems have had the not unprecedented fate of being called merely literary in their inspiration, and it cannot be denied that his borrowings were probably many; yet in the mediæval way he considered himself sincerely original, and much in his work supports the claim. The amount of actual incident that he takes over from his own life is large, especially in the noble sonnets that deal with horsemanship and knightly exercise, and his story in one point was radically different from Petrarch's or Dante's. His love was known and returned; the bar between Penelope and himself was one of honor, since she was married to another; this lofty sense of this kind of honor was Sidney's characteristically English contribution to the world-theme of love.

In most cases the "love passionings" of Sidney's imitators were of the head rather than of the heart. This undeniable note of artifice has led to serious doubts as to the sincerity of the greater sequences—Sidney's, Spenser's, and Shakespeare's. With due allowance for the undoubted imitations in all three poets, it remains true that their sonnets, as distinguished from others, have the very tone of sincerity. It would be an interesting question, though hard to answer, whether through the impress of similar ideals of love and courtly behavior, the poets in England and their fellows in France had not acquired for the moment the same channels of thought—whether the similarities in their work are not frequently coincidences rather than borrowings.

Sidney's 'Astrophel and Stella' had been preceded by Thomas Watson's 'Hekatompathia' (1582), a series of pedantic poems on love themes, which had the respect but not the imitation of his contemporaries. In 1592 appeared Samuel Daniels' (1659-1731) 'Delia,' in honor of the Countess of Pembroke, Sidney's sister—a finely written series remembered for some charming lines and for the oft-imitated "Care-charmer Sleep," itself an imitation from Desportes. 'Parthenophil and Parthenophe' (1593) by Barnabe Barnes (1569-1609), though it contains in its enormous mass some poems of charm, is clearly literary in inspiration. Lodge's 'Phillis,' in the same year, reverts to the pastoral background of the romances; the sonnets have the same charm as Lodge's incidental lyrics.

Spenser's 'Amoretti' (1595) record his own love story, and should be read with his beautiful wedding song, the 'Epithalamion.' The sonnets exhibit almost in excess his sweetness of language and his idyllic, picture method; there is an all but fatal smoothness of surface that makes the thought elusive. But the noble tone, the Platonic emphasis on beauty of soul, indicates the true Spencer, and the sonnets rank third among Elizabethan series.

Shakespeare's 'Sonnets,' printed in 1609 but written much earlier, mark the supreme reach of this kind of writing. Some of the attention they have received comes from the poet's greater fame as a dramatist; some of it comes from the mystery that still on many sides envelopes the sonnets; but the story itself, the conflict of the two angels of friendship and of dark love, is the most striking of the sonnet themes, and the powerful directness with which the subject for the most part is treated, places the series above anything else of its kind in English. Natural as the sonnets seem, however, and spontaneous as the themes appear, yet comparison with other sequences shows that Shakespeare assimilated much of his predecessors; how much of his own life is in the story remains the puzzle of his biographers.

In the years immediately following the sonnet-writing, the characteristic vehicle of **Elizabethan** non-dramatic poetry was the **song-book.** The manuscript miscellanies of Henry VIII.'s time had contained the notes as well as the words of songs, and the Elizabethan period was rich in musicians as well as poets. In 1588 Nicholas Younge published his 'Musica Transalpina,' a collection of Italian madrigals with English words. The madigral was a strict musical form, a contrapuntal part song, built up on many repetitions of a musical theme, and so needing few words—only a short poem, or part of a longer one. With the development of the lute and the growing popularity of lute music, came the song built on a melody, with harmonized accompaniment — what the Elizabethan called an Air. John Dowland, the greatest of the lutanists, introduced this new kind of song in 1597, in his 'First Book of Songs or Airs,' and the form was perfected, in both words and music, by Thomas Campion (——?-1619) in several books of Airs. As the Air was but a short melody, repeated without change, it needed for words a short lyric of several stanzas. This need encouraged the composition of short, finely wrought songs, frequently in the lighter vein, such as Campion himself wrote, and such as became a model for Herrick (q.v.).

Beginning with Wyatt, there had been a vein of satire in Elizabethan poetry. Gascoigne (1525-1577) in his 'Steel Glass' (1576), Lodge in his 'Fig for Momus' (1595), Joseph Hall in his 'Virgidemiarum' (1597), and Marston in his 'Satires' (1598), and many lesser writers, kept the tradition alive. One other minor strain, which was destined to flower later into larger expression, was religious verse—often crude and moralizing, as in the miscellanies, often fantastic, as foreshadowing Donne (q.v.), but often devout. In Robert Southwell (1561-1595) this writing becomes passionate and of the first quality. His 'Saint Peter's Complaint' (1595), contains that one poem, "The Burning Babe," that Ben Jonson preferred to all his own work.

These are the main forms of Elizabethan non-dramatic poetry. If we except the 'Faërie Queene,' the genius of the age is perhaps best seen in the drama. But in these other forms the Elizabethan mind preserved for us a broad and varied record of its amazing power to absorb the literary past, and to feel deeply its own experience.

JOHN ERSKINE,
Associate Professor of English, Amherst College.

Elizabethan Literature—Prose. Elizabethan prose has neither the significance nor the splendor of Elizabethan poetry. The greatest masters, Sidney, Lyly, Hooker, have no supreme interest of matter or style; and Bacon belongs in spirit to another age with other ideals and another *ethos*. But the shaping of English speech as an instrument for the science and thought of the 17th century was the result of the efforts of Elizabethan prosemen. Before the period itself commences, the work of More, Elyot, and Latimer, of Coverdale, Tyndale, and the editors of the English Prayerbook, had already brought a simple and vigorous vernacular into being; but the ancestors of Augustan prose were the group of Cambridge scholars, Cheke, Wilson, and Ascham, whose writings, with the exception of the 'Scholemaster,' antedate the accession of Elizabeth. This group devoted considerable attention to the study of English rhetoric; they aimed at plainness and purity of speech and the formation of a literary vernacular in emulation of the classics; they objected to archaisms and affectations of all sorts, and Wilson's condemnation of «ink-horn terms» is one of the significant *loci* of English criticism. The introduction of classical studies as a result of the revival of learning had necessitated a complete revision of the mediæval curriculum, and Ascham's 'Scholemaster,' published posthumously in 1570, follows the fashion set by the humanists of Italy, France, and Germany, in a very large number of pedagogical treatises. Like these humanists, it was his purpose to indicate the education necessary to a cultivated gentleman. His own prose style is simple and direct, borrowing the more inconspicuous excellences of Latin prose. But his mood is in some respects that of the Puritan; and in his suspicion of romance and of the growing Italian influence, he is at odds with the whole spirit of Elizabethan life and letters. Prose and poetry alike were to be saturated with the Italianate spirit which he contemns.

Ascham is in some measure the father of that whole school of Elizabethan stylists, whose model was «eloquence» in the classical and humanistic sense, and who disregarded the ornate and «aureate» tendencies of Continental prose. The full and rich notes of Hooker are the final culmination of this manner. The first four books of the 'Ecclesiastical Polity' were published in 1594: several schools of *Novella Elocutio* had intervened since the composition of the 'Scholemaster,' but they have not affected the purity and directness, the calm and judicious argumentation of Hooker's style and manner. In this great book, moderation and passion temper each other after the fashion of the best Latin prose; and Hooker realizes the ambitions of the earlier English humanists who had made this their ultimate goal. Other models and other ambitions could alone make it possible to arrive at a higher standard than that which Hooker achieves at his best. Much of the book is unreadable to-day, like the technical arguments of the Attic orators; but its soaring passages, like theirs, are monuments of the race and religion whose ardor and conviction they express.

Directness and vigor were also put to far different uses both in secular and in religious polemics. Of the latter, the Martin Marprelate Controversy relating to the problem of church discipline, which raged between 1587 and 1590, gave opportunities which secular pamphleteers only too soon made use of. The significance of 'Hay any work for Cooper?' and 'Pap with a Hatchet' has been greatly overrated; in them the instrument which the Cambridge group had prepared for use was blunted and used as a cudgel. Nor can much more be said of the controversial writings of Nash, Greene, and Harvey, in which is illustrated the nearest Elizabethan approximation to modern journalism, but with manners and morals untempered by a wholesome or cultivated public opinion. Other miscellaneous writings of these men, and of Dekker, Breton, and others, are concerned with every variety of subject, and their models include Aretino, Rabelais, Dedekind, as well as other Continental writers of a wholly different type.

Literary criticism began in this period and employed for the most part the prose style whose tradition goes back to Ascham. In content and structure its models were Italian, either directly or through the French; and its significance consists in the fact that it was the means of introducing literary ideas which had been current in Italy for nearly a century. The group of the Areopagus, which parallels the Pléiade of France in a few more or less important respects, found its highest critical expression in the 'Defence of Poesy' of Sir Philip Sidney, written about 1580, and published posthumously in 1595. Sidney's ideals of prose style are not those of Ascham, but his practice here is without those excesses and affectations which in the 'Aracadia' furnish the model for a whole school of imitators. His book is an impassioned apology for the poetic art against the onslaught of the Puritans; but the objections which it refutes are universal, and its answers to these questions have in themselves, too, the temper of universality. There are parallels for all its ideas in the almost contemporary works of Frenchmen and Italians. They, too, from the dawn of the Renaissance, as in Boccaccio's 'Genealogy of the Gods,' which Sidney doubtless knew, had written defences of poetry; but Sidney's is an English book, and in its passion, unity, and general spirit, seems the native product of Elizabethan genius. Puttenham's 'Arte of English Poesie' conforms more to the model of the formal treatises which the Italians devoted to the theory and practice of poetry. Its purpose, like theirs, is to consider the whole range of criticism; it deals with the history, dignity, forms, metre, and ornaments of poetry, continually illustrating the theory both by example and by anecdote. The critical work of Jonson belongs to the Jacobean age, and its ideals and its style indicate the great changes that had taken place since the 'Defence of Poesy.' It is impossible to date the 'Discoveries' with any degree of certainty, but no word it contains antedates the death of Elizabeth. Jonson, despite the fame of this work, enunciates no single original idea in regard to the art of literature; but the luminous utterances of the later Latin rhetoricians, and the rational classicism of the Dutch critics, are alike embedded in his robust prose, and become an influence on English criticism even after the Restoration.

The formal treatise or preface was the vehicle of criticism in the Elizabethan age; the chief vehicle which it was to use in future was introduced into England by Bacon at the very end of the 16th century. Montaigne is the father of the modern essay; and to him Bacon owed the name and a number of definite ideas. But in everything else no two works could differ more than theirs. The air of loquacity, the personal anecdote, the amused curiosity, the vivid imagery of Montaigne are not to be sought for in the essays of Bacon. The statesman utters his brooding thought in curt and clipt sentences; Seneca and Pliny here speak English; and the sententious manner enters our speech, destined to saturate prose and verse, and resulting after many changes in the pointed couplets of Pope. Each sentence is its own world and has its own message. Bacon, even in his scientific work, has been called a mere phrase maker by a modern scientist whose distinction in this respect is not unlike his own; in the essays this power is unrestrained by the need of argument and experiment. Emerson is the great American example of this dogmatic use of the disjointed sentence, and like Bacon he, too, has fed deeply on the thought of Montaigne.

A wholly different ideal of prose style, disdaining directness and simplicity, was current throughout the Elizabethan age, and found its most natural expression in the novel. Fenton's version of Bandello, adapted through the French, and the varied collection of Painter's 'Palace of Pleasure,' introduced the Italian *novella* into England. Their interest is almost wholly in the story, and Herodotus and Boccaccio are made to speak the same language of fiction. In Pettie's 'Petite Pallace of Pettie his Pleasure,' which is modelled on the work of Painter, a new element intrudes itself, and the style which culminates in Lyly may be said to have been inaugurated. The sources of Euphuism have been sought in individual works of Continental literature, notably in those of Guevara; but modern scholarship finds in it simply one manifestation of a disease which was rife throughout Europe at this period, as a result of the disintegration of Humanism. The excesses of the Ciceronians find a parallel in the antithetical balance of Lyly's sentences; and the absurd imagery was a natural result of a literature which had exhausted its content and sought for originality in affectation of manner. This explains the kindred writings on the continent; and although English prose was young, it could not fail to be affected by these influences. The well known marks of euphuism, the so-called «parisonic antithesis,» the «unnatural natural history,» and the like, may all be explained on these grounds. 'Euphues' itself is in some senses a novel of psychology and character rather than of incident; but its chief purpose is the fashioning of a perfect gentleman after the manner of Castiglione's 'Courtier.' Here Lyly's purpose meets Spenser's; and 'Euphues' may be considered as the connecting link between the purely pedagogical treatise like the 'Scholemaster' and the final poetic idealisation of Renaissance education in the 'Faerie Queene.' The vogue of Euphuism is indicated by the number of its imitators; but it is unnecessary to consider the forms which Euphuistic romance assumed at the hands of Lodge, Greene, and others.

Sidney is credited by his contemporaries, notably Drayton, with having put an end to this fashion; but if the 'Arcadia' is referred to, it can only be said that one affectation has succeeded another. The 'Arcadia,' which has come down to us as a large, posthumous fragment, is the chief representative in English of the pastoralized romance. It owes much to Herberay des Essarts's French version of the 'Amadis of Gaul,' and something to the 'Diana' of Montemayor; in it the Renaissance transmutations of Greek romance find a climax. The mannerisms of Sidney's style are not those of the archaic or affected word, nor of «unnatural natural history,» nor of alliterative antithesis; but the exaggerated imagery, the pomp, the prettiness of the Spanish romances are mingled in the 'Arcadia' in an inextricable jungle of sentence and paragraph. Its vices are those of *conceptismo* rather than of the parallel Spanish vice of *culteranismo*. The mild and modulated Ciceronianism of Hooker, and all of Latin *eloquentia* that Cheke and Ascham had hoped to introduce into English speech, are wholly absent. The 'Unfortunate Traveller' of Nash may be mentioned as an indication of a tendency antipodal to the chivalric pastoralism of Sidney; it introduces in a racier style a picaresque experiment in English fiction between the period of 'Guzman' and 'Lazarillo.' But the novelist and the preacher in general succumbed to the temptations of the ornate style: the novel throughout the period of its origins was tainted with Euphuism or Arcadianism, and pulpit oratory acquired a definite mannerism, which persisted until Eachard, Glanvill, and other pamphleteers ridiculed it out of existence.

With the accession of James I. Jacobean erudition and science superseded the creative impule of the Elizabethans. Bacon and Jonson represent the new sententious manner at its best; other writers lose themselves in a sea of detail; still others add a hectic fervor to thought or feeling. But these things do not properly belong to the Elizabethan spirit. The opposition of the vernacular and ornate styles; the inauguration of formal criticism and prose fiction; the passion for controversy; these are the main impulses of Elizabethan prose.

I, No. 9).

J. E. Spingarn,
Adjunct-professor of Comparative Literature, Columbia University.

Elizabethpol, ĕ-lē-zä-bet-poly, or **Yelizavetpol**, Russia, (1) a government of Transcaucasia, Asiatic Russia; area 16,721 square miles; pop. 890,563, of whom about 60 per cent are Azerbaijan Tartars, 30 per cent Armenians and the balance Kurds, Russians, etc. Chief town Elizabethpol. It is bounded on the north by Tiflis, Daghestan, and Zakataly, east by Baku, south by

Persia, and west by Erivan. It belongs partly to the region of the Little Caucasus and is partly covered with steppes, in the west consisting of high mountains whereas the east is more level. The Kur River and several smaller streams are the chief waterways. Agriculture is the principal industry, the valleys being fertile and well cultivated. Wine is produced in considerable quantities. The rearing of live stock is largely carried on in the steppes. The mountain slopes are well wooded and there are rich deposits of minerals, especially of copper, cobalt and iron ore which are found and mined in large quantities. The Transcaucasian Railway crosses the government, which is divided into eight districts, Elizabethpol, Zanglzur, Aresh, Jebrail, Jevanshir, Shusha, Kazakh and Nukha. (2) A city in the Caucasus, capital of the government of the same name; located on an affluent of the Kur River about 120 miles by rail southeast of Tiflis. It is situated in a rich agricultural region and in addition to raising agricultural products and fruit, the inhabitants are extensively engaged in the silk-worm industry. The city consists of two sections, the old and the new; the former is poorly built with crooked streets and low-roofed houses and is occupied chiefly by Mohammedans; the latter is well built and contains several handsome buildings, churches, mosques, etc. One of the mosques dates from early in the 17th century. There are also an ancient mausoleum and a bazaar. Ancient remains are found in the vicinity of the city and the old Turkish fortifications may still be seen. The city is very old and changed hands between Persians, Arabs and Khozars as early as the 7th century, later came into the possession of the Mongols, Georgians, Persians and Turks, was taken by the Russians in 1796 and finally annexed to Russia in 1813, receiving its name in honor of Elizabeth, daughter of Alexander I. In 1826 the Persians were defeated here. Pop. 35,129.

Elizabethtown, Ky., city, county-seat of Hardin County; on the Louisville & N., and the Illinois C. R.R.'s; about 40 miles south of Louisville. The city is the centre of the trade in asphalt for which the county is noted, and it does a large business in live stock and agricultural products. Pop. 2,000.

Elizabethtown, N. Y., village, county-seat of Essex County; on the Bouquet River, 12 miles west of Westport, the nearest railroad station. Westport is on Lake Champlain and on the Delaware & Hudson Railroad. Elizabethtown is in the Adirondacks, on a height overlooking several beautiful valleys. It is a famous summer resort, and has quite a population in July and August. Pop. (1900) 491.

Elk, or **Moose,** the largest living representative of the deer family, the genus *Alces,* in America, called the moose. It is six and one half to seven feet tall at the shoulder; weighs from 1,000 to 1,500 pounds; is grayish-brown in color with light underparts, and carries a pair of magnificently spread antlers. These are peculiar in that they grow at right-angles to the plane of the face, and are broadly palmate, in two portions, the anterior usually the larger of the two. These antlers have been known to weigh as much as 60 pounds. The elk is further distinguished by having long limbs, a short neck, long flapping ears, a long narrow head, terminating in a broad overhanging muzzle, and small, sunken eyes. The tail is merely rudimentary. In captivity, or even in comparison with other deer, the elk is ugly and rather ungainly. Yet, seen in the forest he presents a thoroughly majestic front to the hunter, and can move as swiftly and more noiselessly than the less bulky and more graceful members of the family. See MOOSE.

The elk of Europe is found on the continent, and to the far north in Scandinavia, northern Russia, and northern Prussia. In America, the moose has retreated to a great extent, toward the Northwest; and it is fairly common throughout Canada and Labrador. The summer home of the elk is near fresh water, where he can feed upon the succulent herbage. In winter he retires to the fastnesses of heavily wooded timber-land, where his food consists of twigs, leafbuds, and certain species of lichens. Like the red-deer, the elk fights for possession of his consort; and fierce combats are waged in the early autumn between stags whose antlers have matured during the retirement of summer. The peculiar blood-curdling challenge, uttered by the male at this season, is reproduced through a short trumpet of rolled birch-bark by both Indian and white hunters, who thus lure the eager elk within shooting distance of their ambush. On account of the power of endurance and strength of the creature, it is frequently made symbolic; and in many localities in Canada, persons of unusual physical power are said to be «As strong as a bull-moose.» It is easily domesticated and made to draw sledges.

Of fossil species, the best known is the Irish Elk, found in the Pleistocene strata, and distinguished by its enormous antlers, the tips of which are sometimes 11 feet apart, but which differ from those of living species in that the beam is flattened into a palm. To sustain their great weight, unusually large and strong limbs, and neck vertebra, were required. While found chiefly in the peat bogs of Ireland, its remains have been discovered also in Great Britain and throughout Europe in lacustrine deposits, brick clay, and ossiferous caves.

Elkesaites. See ELCESAITES.

Elk'hart, Ind., city, in Elkhart County, at the confluence of the St. Joseph and Elkhart Rivers, and on the Cleveland, C., C., & St. L., the Lake Shore and the Elkhart & W. R.R.'s.; 101 miles east of Chicago. It is a railroad centre and shipping point for a large agricultural region. The rivers afford excellent water power. The Lake Shore railroad shops are located here and the manufacturing interests include brass, carriage, starch, bicycle, and paper factories. Elkhart is the seat of Elkhart Institute and has public schools, business colleges, and high school, daily and weekly newspapers, gas and electric lights, electric railways, waterworks and two national banks. Pop. (1900) 15,184.

Elk'horn, a river in Nebraska formed by the junction, in Madison County, of the North Fork, which has its rise in Brown County, and the South Fork which rises in Knox County. The general course is southeast, 260 miles, when it flows into the Platte River.

Elkin, William Lewis, American astronomer: b. New Orleans 29 April 1855. He was educated at the Royal Polytechnic School in Stuttgart, Germany, and was graduated in 1880 at the University of Strasburg. He then went to the Cape of Good Hope on the invitation of Sir David Gill, English astronomer there, and took part with him in observations with the heliometer for the determination of stellar parallax, these determinations being the most accurate of the kind ever made up to that time. He became astronomer in 1884 and director in 1896 of the Yale College observatory.

Elkins, Stephen Benton, American politician: b. Parry County, Ohio, 26 Sept. 1841. He removed to Missouri when a child; was graduated at the University of Missouri in 1860; and admitted to the bar in 1863. During the latter year he went to New Mexico, where he was a member of the Territorial legislature in 1864–5; and the Territorial delegate in Congress in 1873–7. Subsequently he removed to West Virginia. In 1891–3 he was secretary of war, and in 1894, 1000, and 1907 was elected to the United States Senate.

Elkins, W. Va., city and county-seat of Randolph County; on both sides of the Tygarts Valley River and on the West Va. C. & P. (Wabash) and its branches, the Coal & Iron and the Coal & Coke R.R.s; 60 miles south of Grafton and 130 miles northwest of Charleston.

Industries.— Elkins is in the centre of vast timber areas, and nearby are large deposits of coal, glass, sand, limestone, potter's clay, fire clay and shale suitable for the manufacture of pressed brick and tiling. The industries include railroad car and machine shops, brick works, ice plant, foundries and machine shops, tannery, boiler works, nail factory, several planing mills, etc.

Public Works, Banks, Etc.— The principal streets are paved with brick or macadamized limestone, and walks are laid with brick. The city owns the water-works, which pump the water from the Tygarts Valley River. The streets are lighted by electricity and natural gas is furnished for domestic and manufacturing purposes. There are a national bank and a trust company in the city, with combined capital of $300,000 and deposits of about $1,200,000.

Churches and Schools.— The city contains seven churches, representing the leading denominations. There are a graded public school and a high school. Elkins is also the seat of Davis and Elkins College. Pop. (1900) 2,016; (1906) about 5,000.

Elks, Benevolent and Protective Order of, a convivial, charitable, and benevolent organization founded by members of the theatrical profession in New York in 1868, but now admitting to membership men in other professions and occupations. The order has one grand lodge and 951 sub-lodges throughout the country. The membership in the United States numbered more than 200,000, including many prominent men. Though not a beneficial order, it is claimed that it expends more in unostentatious charity than any other organization in the world. The benefits disbursed since organization amount to $1,250,000, with an annual average distribution at present of upward of $150,000.

Ella'gic Acid or **Bezoardic Acid,** $C_{14}H_6O_8$, is separated from Oriental bezoars by dissolving them in cold strong potash, away from the air, passing a current of carbolic acid, collecting the ellagate of potassium, washing and recrystalizing it, and then liberating the ellagic acid by hydrochloric acid. It is insoluble in water, but dissolves in alcohol. It is a pale yellow, tasteless, crystalline powder, decomposed on heating. With the bases it forms salts, which are not very well known; they are crystalline, and insoluble or sparingly soluble in water. The lead and barium compounds are yellow. This acid can also be obtained from gallic acid, of which it is a product of oxidation.

Ellenborough, ĕl'lĕn-bŭr-ō, **Edward Law,** Lord, English lawyer: b. Great Salkeld, Cumberland, 16 Nov. 1750; d. London 13 Dec. 1818. He was educated at Cambridge, and was called to the bar in 1780. On the trial of Warren Hastings in 1785, Erskine having refused to undertake the defense, Law served as leading counsel. It required no little courage to encounter such opponents as Burke, Fox, Sheridan, and other eminent men of the time, who conducted the impeachment. Law, as is well known, obtained the victory. In 1801 he was made attorney-general, and in 1802 became lord chief justice of the king's bench, and was created baron. In Parliament he was opposed to the emancipation of the Catholics. He held the office of chief justice for 15 years.

Ellenborough, Edward Law, 1st Earl of, English statesman: b. 8 Sept. 1790; d. near Cheltenham 22 Dec. 1871. He was educated at Eton and Cambridge; entered Parliament as representative of St. Michael's in 1814, and in 1818 succeeded his father as second baron, and entered the House of Lords. He was lord privy-seal in 1828, and in 1841 accepted the governor-generalship of India. He arrived in Calcutta in time to take control of the Afghan war, which was brought to a successful issue. Scinde was conquered by Sir Charles Napier, and annexed in 1843. This was followed by the conquest of Gwalior. The conduct of the governor-general, however, gave great dissatisfaction at home. He was consequently recalled by the East India Company early in 1844. Under Lord Derby's government in 1858 he held the office of president of the board of control from February to June, during which he wrote a despatch censuring the policy of Lord Canning as governor-general of India, which caused much discussion, and led him to resign his office.

Ellenville, N. Y., village of Ulster County, at the foot of Shawagunk Mountain, on the main line and on the Ellenville and Kingston division of the New York, Ontario & Western R.R., 18 miles N. of Middletown. The first house was built in 1805, a post-office established in 1823, and the village incorporated in 1856. It has several denominational churches, a high school and other educational establishments, two national and one savings bank, and its industries include zinc mining, manufactures of cutlery, overalls, artificial stone, and wood wares, employing about 300 operatives. Pop. (1901) 2,879.

El'ler, Johann Theodor, German chemist: b. Plötzkau, in Anhalt-Bernburg, 29 Nov. 1689; d. Berlin 13 Sept. 1760. In 1721 he was appointed Anhalt-Bernburg physician; in 1724, professor of anatomy in Berlin; in 1735, physician to Frederick the Great; in 1755, privy councilor and director of the physical class of the Academy of Sciences. His papers were published in the 'Memoirs of the Berlin Academy,' and among them is a long and interesting review of the opinions held respecting the elements from the earliest times down to his own day. He also published a series of curious microscopic observations upon the change of blood corpuscles by the addition of different salts, tinctures of plants, and other solutions. Eller was undoubtedly a man of great learning and abilities, but his writings do not indicate a high degree of originality.

Ellerians, a sect of fanatics which arose in 1726, and had for its founder Elias Eller, a ribbon-weaver, who was born in 1690 at Ronsdorf in Berg. He was influenced in his religious beliefs by reading the works of Jacob Böhme, and other mystical writings. The sect committed great excesses, and became very numerous. See Böhme, Jacob.

Ellery, William, American patriot: b. Newport, R. I., 22 Dec. 1727; d. there 15 Feb. 1820. He sat in the Congress of 1776, and was one of the signers of the Declaration of Independence. From 1790 till his death, he retained the office of collector in his native place.

Ellesmere, ĕlz'mēr, **Francis Egerton,** Earl of, English author: b. London 1 Jan. 1800; d. there 18 Feb. 1857. His 'The Pilgrimage and Other Poems' (1856) constitutes his most valid title to fame, though he wrote much and well on biographical, historical, and literary subjects.

Ellesmere Land, the most northern region of the continent of North America, discovered by Baffin in 1616. The western part of this region was explored and mapped by Sverdrup, Otto (q.v.) in 1899. Ellesmere Land is a high plateau, without human inhabitants; a few reindeer, musk-oxen, and wolves find sustenance there. It is separated from Greenland by Smith Sound.

El'let, Charles, American engineer: b. Penn's Manor, Bucks County, Pa., 1 Jan. 1810; d. Cairo, Ill., 21 June 1862. He was educated at the Polytechnic School in Paris, and on his return to America held various responsible engineering posts. He built at Fairmount, Philadelphia, the first wire suspension bridge in the United States, and in 1845 declared that a bridge could be built at Niagara below the Falls adapted for railway purposes. In the Civil War he equipped nine Mississippi River steamboats as rams, and with them defeated a fleet of Confederate rams, but died of wounds on that occasion.

Ellet, Elizabeth Fries Lummis, American prose writer: b. Sodus Point, N. Y., October, 1818; d. New York 3 June 1877. She was popular in her day, and among her books are a translation of Silvio Pellico's 'Euphemia of Messina' (1834); 'Poems, Original and Selected' (1835); 'Characters of Schiller' (1842); 'Pioneer Women of the West' (1852); 'Novelettes of the Musicians' (1852); 'Queens of American Society' (1867); 'Court Circles of the Republic,' with Mrs. R. E. Mack (1869); 'The Practical Housekeeper'; 'Evenings at Woodlawn'; 'Women Artists in All Ages.'

Ellice, ĕl'ĭs, or **Lagoon Islands,** a group of coral islands, situated north of the Fiji and northwest of the Samoan group. They extend for 360 miles in a direction northwest to southeast, and form nine groups, the largest islands being Sophia or Rocky Island, Nukulailai or Mitchell, Ellice, Nukufetau, Vaitupu, Netherland, and Lynx. The inhabitants almost all speak a Samoan dialect, and have traditions of a migration from the Samoan islands. They have long been Christianized, and reading and writing are general. The cocoanut is widely cultivated. These islands were annexed by Great Britain in 1892. Area, 14 square miles. Pop. 2,400.

Ellichpur, ĕl-ich-poor', India, town in Ellichpur district, Berar, once large and prosperous. There is a military cantonment within two miles. The town contains many interesting ruins, including a palace, several fine tombs, and an old well. Pop. 36,240.

El'licott, Andrew, American astronomer and civil engineer: b. Bucks County, Pa., 24 Jan. 1754; d. West Point, N. Y., 28 Aug. 1820. His father founded the town of Ellicott's Mills, Maryland, where the younger days of his son Andrew were devoted to the study of the sciences and practical mechanics. The latter's scientific attainments early attracted public attention, and from the Revolution to the day of his death he was employed in the fulfilment of trusts conferred by the general or State governments. About 1785 he removed to Baltimore, and represented that city in the State legislature. In 1789 he was appointed by President Washington to survey the land lying between Pennsylvania and Lake Erie, and during that year made the first accurate measurement of the Niagara River from lake to lake, with the height of the falls and the fall of the rapids. In 1790 he was employed by the government to survey and lay out the federal metropolis. In 1792 he was made surveyor-general of the United States, and in 1795 superintended the construction of Fort Erie at Presque Isle (now Erie, Pa.), and was employed in laying out the towns of Erie, Warren, and Franklin. In 1796 he was appointed by President Washington commissioner on behalf of the United States under the treaty of San Lorenzo el Real, to determine the southern boundary separating the United States territory from the Spanish possessions. The results of this service, embracing a period of nearly five years appear in his 'Journal' (published 1803). Upon the completion of this service he was appointed by Gov. McKean of Pennsylvania, secretary of the State land office, the duties of which he performed to the year 1808, and in 1812 became professor of mathematics at West Point. In 1817, by order of the government, he proceeded to Montreal to make astronomical observations for carrying into effect some of the articles of the Treaty of Ghent.

Ellicott, Charles John, English Anglican prelate: b. Whitwell, Stamford, England, 25 April 1819. He was educated at St. John's College, Cambridge, and after being professor of divinity in King's College, London, Hulsean lecturer and professor of divinity at Cambridge, and dean of Exeter, was appointed bishop of Gloucester and Bristol in 1863. In 1897 the diocese of Bristol was separated from that of Gloucester, Bishop Ellicott remaining at the head of the latter diocese. He was for 11 years chairman of the scholars engaged on the revision of the New Testament translation, and has published commentaries on the Old and New Testaments, as well as 'Historical Lectures on the Life of Christ'; 'Modern Unbelief' (1877); 'Some Present Dangers of the Church of England' (1878); 'Spiritual Needs in Country Parishes' (1888); 'Sacred Study' (1892-4); 'The Revised Version of Holy Scripture' (1901); etc.

Ellicott, Henry J., American sculptor: b. near Ellicott City, Md., 1848; d. Washington, D. C., 11 Feb. 1901. His best-known works include bronze statues for the 1st and 2nd Pennsylvania Volunteers on the battlefield at Gettysburg, the equestrian statues of Gen. Hancock in Washington and Gen. McClellan in Philadelphia; and memorial monuments in various parts of the United States.

Ellicott City, Md., county-seat of Howard County; on the Patapsco River; eight miles west of Baltimore. St. Charles College (R. C.) in charge of secular clergy, and Rock Hill College, in charge of Brothers of the Christian Schools, are located here. The manufactures and trade are chiefly local. Pop. 1,408.

El'linwood, Frank Fields, American clergyman and author: b. Clinton, N. Y., 20 June 1826. He was graduated at Hamilton College in 1849; was ordained a minister in the Presbyterian Church in 1853; and became secretary of foreign missions for that denomination in 1871. His chief works are: 'The Great Conquest' (1876); 'Oriental Religions and Christianity' (1892); 'Questions and Phases of Modern Missions' (1899).

El'liot, Daniel Giraud, American zoologist: b. New York 7 March 1835. He made zoology a special study from his youth; traveled in Europe, Africa, and parts of Asia in 1856-78; subsequently in Canada, Alaska, South America, and the greater part of the United States. He afterward became curator of zoology in the Field Columbian Museum. He has published: 'The Pheasants'; 'Birds of North America'; 'The Grouse'; 'Birds of Paradise'; Hornbills'; etc. He has been decorated 10 times by various European governments for his researches in natural science.

Elliot, Sir **Gilbert,** Scottish philosopher and poet: b. Teviotdale September 1722; d. Marseilles 11 Jan. 1777. His song of 'Amynta' beginning "My sheep I neglected, I broke my sheep hook," is famous; he also wrote occasional philosophical papers.

Elliot, Henry Rutherford, American journalist: b. Woodbridge, N. J., 21 April 1849; d. New York City, 18 April 1906. He has published: 'The Basset Claim, a Story of Life in Washington' (1887); 'The Common Chord, a Story of the Ninth Ward' (1888); etc.

Elliot, Jane, Scottish poet, sister of Sir Gilbert Elliot: b. Teviotdale, 1727; d. there 29 March 1805. She wrote 'The Flowers of the Forest' (1756), a song of Flodden Field.

El'liott, Arthur Ralph Douglas, Scottish lawyer and author: b. 17 Dec. 1846. He was educated at Edinburgh and Cambridge, was called to the bar in 1880, and was a member of Parliament for Roxburghshire 1880-92, and for the city of Durham 1898-1900. He has been editor of 'The Edinburgh Review' from 1895 and is the author of: 'Criminal Procedure in England and Scotland'; 'The State and the Church' (1881).

Elliott, Charles, American Methodist clergyman: b. Glenconway, County Donegal, Ireland, 16 May 1792; d. Mount Pleasant, Iowa, 3 Jan. 1869. He came to the United States in 1814 and became prominent in the Methodist denomination. He was a professor of languages at Madison College, Uniontown, Pa., 1827-31, and president of Iowa Wesleyan University 1856-60 and 1864-7. He published: 'Treatise on Baptism' (1834); 'Sinfulness of American Slavery' (1851); 'The Bible and Slavery'; etc.

Elliott, Charles Loring, American painter: b. Scipio, N. Y., December 1812; d. Albany, N. Y., 25 Aug. 1868. His works consist almost exclusively of portraits, many of which are of eminent American citizens, and are remarkable for the fidelity of the likeness and their vigorous coloring. In 1846 he became a member of the National Academy of Design.

Elliott, Charles Wyllys, American novelist and historian: b. Guilford, Conn., 27 May 1817; d. 20 Aug. 1883. Settling in New York, he was one of the founders and trustees of the Children's Aid Society in 1853, and in 1857 was one of the commissioners for laying out Central Park. He published among other works: 'Cottages and Cottage Life' (1848); 'Mysteries, or Glimpses of the Supernatural' (1852); 'The Book of American Interiors'; 'Pottery and Porcelain'; 'Remarkable Characters and Places in the Holy Land'; 'St. Domingo, Its Revolution and Its Hero'; 'Wind and Whirlwind,' a novel; etc.

Elliott, Charlotte, English hymn-writer: b. 17 March 1789; d. Brighton 22 Sept. 1871. She wrote a number of religious poems, which were published under the titles: 'Hymns for a Week'; 'Hours of Sorrow'; 'Invalids' Hymn Book.' The last collection included 'Just as I Am,' a hymn which is widely used, and has been translated in "almost every living language."

Elliott, Ebenezer, English poet: b. Masborough, near Sheffield, 17 March 1781; d. Great Houghton, near Barnsley, 1 Dec. 1849. At first a foundry hand, his poetic gift was used in denouncing the exploitation of the proletaria' by a capitalistic oligarchy; yet the bitterness and exaggerated rhetoric one would expect under such circumstances are wholly absent from 'Corn Law Rhymes' (1831), and 'More Prose and Verse' (1850). He was famed in his day as "The Corn Law Rhymer."

Elliott, Sir **Henry Miers,** English historian: b. Westminster 1808; d. Simon's Town, Cape of Good Hope, 20 Dec. 1853. Long an Indian civil servant, he compiled 'Memoirs of the History, Folk Lore, and Distribution of the Races of the Northwestern Provinces of India' (1869), and 'The History of India as Told by Its Own Historians: The Mohammedan Period' (1867-77).

Elliott, Henry Wood, American naturalist and artist: b. Cleveland, Ohio, 13 Nov. 1846. In 1862-78 he was private secretary to Joseph

Henry, secretary of the Smithsonian Institution; in 1869–71 artist of the United States Geological Survey; and in 1872–4 and 1890 a special commissioner for the investigation of the Seal Islands of Alaska. His publications include: 'Monograph of the Seal Islands' (1881), and 'Our Arctic Province, Alaska' (1886); 'The Seal Islands of Alaska' (1894).

Elliott, Jesse Duncan, American naval officer: b. Maryland 1782; d. 1845. He entered the United States navy as a midshipman 1804, and in October of 1812 won the first American naval success on the lakes, capturing two British brigs, the Detroit and the Caledonia, near Fort Erie. He commanded the Niagara, in the battles of Lake Erie, September 1813, being second in command to Perry, whom he succeeded in October of the same year as commander of the Lake Erie fleet. In 1815, during the war against Algiers, he was in command of the sloop of war Ontario, under Decatur, being appointed captain in 1818.

Elliott, Maud Howe, American novelist: b. Boston, Mass., 9 Nov. 1855. She is a daughter of Julia Wood Howe (q.v.), and was married to John Elliott, an artist, in 1887. Her writings include: 'A Newport Aquarelle' (1883); 'The San Rosario Ranch' (1884); 'Atalanta in the South' (1886); 'Mammon' (1888); 'Honor'; and 'Phyllida.'

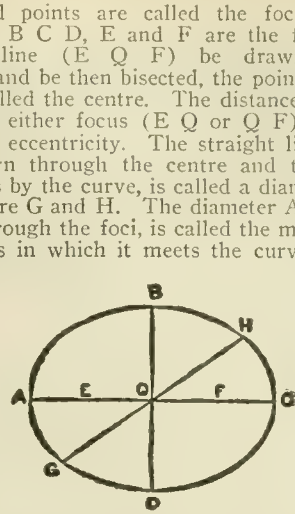
Elliott, Maxine, American actress: b. Rockland, Me. Making her début with E. S. Willard, she played Felicia Umfraville in 'The Middleman' (1890), and later in 'The Professor's Love Story.' She was with Rose Coghlan, and in 1895 went to London with Augustin Daly's company. A member of N. C. Goodwin's company 1896, she played in Clyde Fitch's 'Nathan Hale' (1898); was married to Mr. Goodwin that year, appeared with him in 'When We Were Twenty-One,' and played Portia in the 'Merchant of Venice' (1901).

Elliott, Sarah Barnwell, American novelist. She is a granddaughter of Stephen Elliott (q.v.). Her best-known works are: 'The Felmeres' (1879); 'Jerry'; 'John Paget'; 'Sam Houston'; 'The Durket Sperret' (1898); 'An Incident and Other Happenings' (1899).

Elliott, Stephen, American naturalist: b. Beaufort, S. C., 11 Nov. 1771; d. Charleston 28 March 1830. He was graduated at Yale College in 1791, and was president of the "Bank of the State" from 1812 till his death. His leisure hours were devoted to literary and scientific pursuits, and he cultivated the study of botany with enthusiasm. In 1825 he aided in establishing the medical college of the State, and was elected one of the faculty, and professor of natural history and botany. He was the author of the 'Botany of South Carolina and Georgia' (1821–4).

Elliott, William, American miscellaneous writer: b. Beaufort, S. C., 27 April 1788; d. there. He was educated at Yale, and devoted himself mainly to agriculture and rural sports. His published works include: 'Fiesco,' a tragedy (1850); and 'Carolina Sports by Land and Water' (1856).

Ellipse (Lat. *ellipsis,* from Gr. *elleipsis,* omission), a plane curve of such a form that, if from any point in it two straight lines be drawn to two given fixed points, the sum of these straight lines will always be the same; a geometrical term used in conic sections. These two fixed points are called the foci. In the ellipse A B C D, E and F are the foci. If a straight line (E Q F) be drawn joining the foci, and be then bisected, the point of bisection is called the centre. The distance from the centre to either focus (E Q or Q F) is called the linear eccentricity. The straight line (G Q H), drawn through the centre and terminated both ways by the curve, is called a diameter. Its vertices are G and H. The diameter A C, which passes through the foci, is called the major axis; the points in which it meets the curve (A and



C), the principal vertices. The diameter (B D), at right angles to the major axis, is called the minor axis. Practically, a tolerably accurate ellipse may be drawn on paper by sticking two pins in it to represent the foci, putting over these a bit of thread knotted together at the ends, inserting a pencil in the loop, and pulling the string tight as the figure is described. The importance of the ellipse arises from the fact that the planets move in elliptical orbits, the sun being in one of the foci — a fact which Kepler was the first to discover.

The equation to an ellipse, referred to its centre as origin, and to its major and minor axes as rectangular axes, is $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$, where a and b are the semi-major and semi-minor axes respectively. From this equation it may be shown, by the integral calculus, that the area of an ellipse is equal to πab; or is got by multiplying the product of the semi-major and semi-minor axes by 3.1416. It may also be shown that the length of the circumference of an ellipse is got by multiplying the major axis by the quantity

$$\pi\left\{1-\left(\frac{1}{2}\right)^2\frac{e^2}{1}-\left(\frac{1.3}{2.4}\right)^2\frac{e^4}{3}-\left(\frac{1.3.5}{2.4.6}\right)^2\frac{e^6}{5}-\&c.,\right\}$$

to which there is an excellent practical approximation, namely: $\frac{\pi}{2}\left(a+b\sqrt{2(a^2+b^2)}\right)$

The eccentricity e, is $=\sqrt{1-\frac{b^2}{a^2}}$ and the ellipticity is the ratio $a—b$ to a.

Ellip'sis, in grammar, the omission of one or more words, which may be easily supplied by the connection. It is common, especially in colloquial language, for the sake of brevity, and frequently adds to the strength and perspicuity of the sentence. Hence a more extended use of the ellipsis in rhetoric and poetry. In the hands of a genuine poet or orator the ellipsis has a very telling value. In natural language, from the brevity it affords, the ellipsis becomes in all its phases the language of passion, and especially of sudden and intense emotion; and the imitation of its natural use in this way is to the poet the most powerful instrument for painting passion to the life. The works of all the greater poets, and especially the Hebrew poetry of the Old Testament, abounds with familiar instances of this use of the ellipsis.

Ellip'soid, in geometry, a solid figure produced by the revolution of an ellipse about its axis, and all plane sections of which are ellipses or circles. The earth, generally said to be an oblate spheroid, has been designated also an oblate ellipsoid.

Ellis, Alexander John (originally **Sharpe**), English scientist and philologist: b. Hoxton 14 June 1814; d. London 28 Oct. 1890. He was educated at Shrewsbury, Eton, and Trinity, Cambridge, and devoted himself to mathematics, the scientific side of music, and more especially to philology and phonetics. His translation of Prof. Helmholtz's 'Sensations of Tone' (1875), has taken a place as a standard work on scientific music. In 1848 he published two small works: 'The Essentials of Phonetics'; and 'A Plea for Phonetic Spelling,' and collaborated with Sir Isaac Pitman (q.v.) in framing a phonetic system. His *magnum opus* on 'Early English Pronunciation,' with special reference to Chaucer and Shakespeare, appeared between 1869 and 1889.

Ellis, Edward Sylvester, American writer of school text-books and juvenile literature: b. in Geneva, Ohio, 11 April 1840. For some years he was superintendent of public schools at Trenton, N. J. Besides 'The People's Standard History of the United States' and several school histories, his works include: 'The Boy Pioneer Series' (1883–4); 'The Camp Fires of Gen. Lee' (1887); 'The Hunters of the Ozark' (1887); 'The Great River Series' (1888); 'Storm Mountain,' and many other juveniles.

Ellis, George, English author: b. London, England, 1745; d. April 1815. He was educated at Westminster School and Trinity College, Cambridge, and was one of the junta of wits concerned in the well-known political satire, 'The Rolliad.' He published: 'Specimens of the Early English Poets, with an Historical Sketch' (1790); 'Specimens of Early English Metrical Romances' (1805); and was an intimate friend of Sir Walter Scott.

Ellis, George Edward, American Unitarian clergyman and historical writer: b. Boston, Mass., 8 Aug. 1814; d. there 20 Dec. 1894. He was pastor of the Harvard (Unitarian) Church, Charlestown, Mass., 1840–69; and held the professorship of systematic theology in the Cambridge Divinity School 1857–63. As president of the Massachusetts Historical Society he made valuable contributions to early colonial history. He published: 'A Half-Century of the Unitarian Controversy' (1857); 'History of the Battle of Bunker's Hill' (1875); 'The Red Man and the White Man' (1882); 'The Puritan Age and Rule in the Colony of Massachusetts Bay, 1629–85'; various memoirs, and several biographies in Sparks' 'American Biography.'

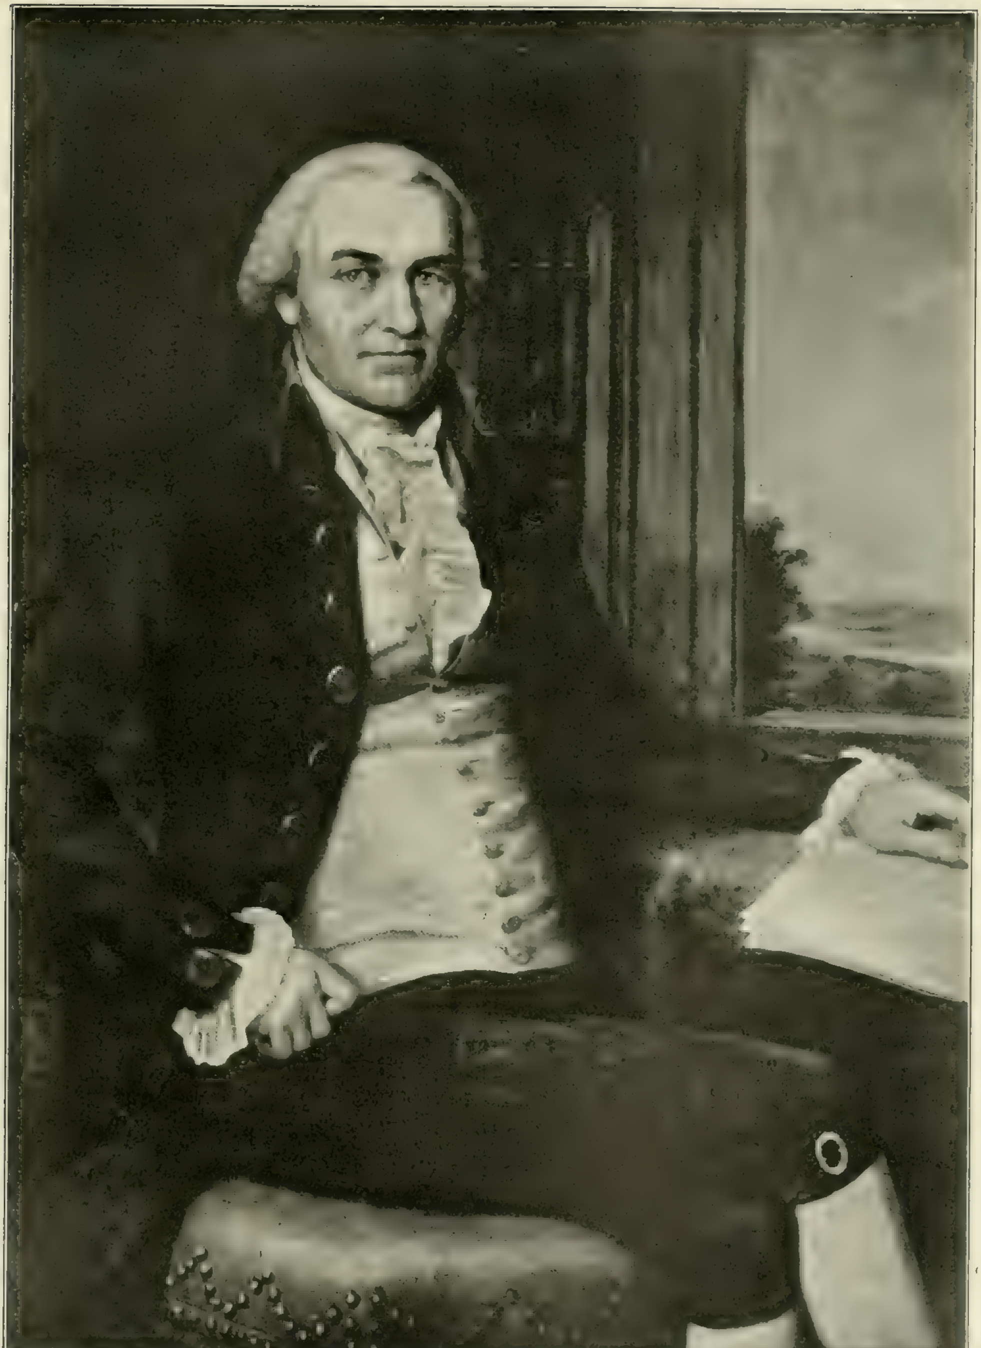
Ellis, Henry Havelock, English scientist and literary scholar: b. Croydon, Surrey, 2 Feb. 1859. He taught school in New South Wales 1875–9, and on his return to England practised medicine for a short time and then devoted himself to literary and scientific work. He is a Fellow of the Medico-legal Society of New York, and honorary Fellow of the Chicago Academy of Medicine, and has been general editor of the 'Contemporary Science Series' from 1889. He edited the 'Mermaid Series of Old Dramatists' (1887–9); and is the author of 'The New Spirit' (1890); 'The Criminal' (1890, enlarged 1901); 'Man and Woman: a Study of Human Secondary Sexual Characters' (1894); 'Sexual Inversion,' being Vol. I. of 'Studies in the Psychology of Sex' (1897); 'Affirmations' (1897); 'The Evolution of Modesty,' being Vol. II. of 'Studies in the Psychology of Sex' (1899); 'The 19th Century: a Dialogue in Utopia' (1900); 'Analysis of the Sexual Impulse,' being Vol. III. of 'Studies in the Psychology of Sex' (1902).

Ellis, Job Bicknell, American botanist: b. Potsdam, N. Y., 1829. With B. M. Everhart he has published: 'North American Pyrenomycetes' (1892); and 'North American Fungi' (1878–93).

Ellis, John, English naturalist: b. London about 1710; d. 1776. He was the first who suggested the idea that the South Sea islands were constructed and raised from the bottom of the ocean by means of zoophytes or the polypi inhabiting different species of coral ('Essay Towards a Natural History of Corallines' 1754). He was for some time agent for the colony of West Florida and the island of Dominica. Among his works is a posthumous one entitled 'The Natural History of Many Curious and Enormous Zoophytes' (1786).

Ellis, Robinson, English classical scholar: b. Barming, Kent, 5 Sept. 1834. He was educated at Rugby and Balliol College, Oxford; and in 1870 became professor of Latin in University College, London. From 1883 till 1893 he was university reader in Latin literature at Oxford, and in the latter year he was elected to the corpus professorship of Latin. His name is chiefly associated with the elucidation of the poems of the Roman poet Catullus. In 1867 he published a critical edition of Catullus ('Catulli Veronensis Liber'), and in 1871 'The Poems and Fragments of Catullus' in the metres of the original, these works being followed by a 'Commentary on Catullus' (1876). Other publications of his include: Ovid's 'Ibis,' with commentary (1881); 'Fables of Avianus' (1887); 'Noctes Manilianæ' (1891); 'The Fables of Phædrus' (1894); and a new recension of 'Velleius Paterculus,' with commentary.

Ellis, Sarah Stickney, English author: b. London, England, 1812; d. Hoddesdon, Herts, 16 June 1872. She was the wife of William Ellis (q.v.). Among her works the best known are: 'Women of England' (1838); and 'Daughters of England' (1842). Still others are: 'Poetry of Life' (1838); 'Summer and Winter in the Pyrenees' (1841); 'The Island Queen' (1846), a poem; 'Fireside Tales' (1848); 'The Brewer's Family' (1863); 'William and Mary' (1865); 'Northern Roses.'



OLIVER ELLSWORTH.

CHIEF JUSTICE OF THE UNITED STATES SUPREME COURT, 1796-1800.

Ellis, T. Mullett, English poet and novelist: b. 29 Dec. 1850. He is the founder and editor of 'The Thrush,' a magazine for original verse, and has published: 'The Earl's Nose,' humorous verse; 'Reveries of World History' (1893); 'The Beauty of Boscastle' (1894); 'Zalma' (1895); 'Tales of the Klondike'; 'God is Love' (1898); 'Kitty, a Story of the Transvaal War'; etc.

Ellis Island, a small island owned by the United States government, and used as an immigrant station. It is situated in New York Bay, one mile southwest of the Battery, where the old immigrant station, Castle Garden, was located. The United States immigrant commissioner has his offices on this island. Immigrants detained for investigation as to compliance with the United States immigration laws, are kept on this island until allowed to land or are deported. See IMMIGRATION LAWS.

Ellora, ĕ-lō'rä, **Elora,** or **Eluru,** ĕ-loo'rä, India, village in the province of Aurungabad; celebrated for some remarkable cave temples, excavated in the solid rock, which in magnitude and perfection surpass all other constructions of the kind in India.

Ellore, ĕ-lōr', India, town, in the Godavari district of the Madras presidency, on the river Jammaler, once the capital of the Northern Circars. It has magisterial and judicial establishments, police station, post-office, etc., a number of Christian missions, and a garrison. There are some manufactures of carpets and saltpetre. Pop. 29,382.

Ells, Robert Wheelock, Canadian geologist: b. Cornwallis, N. S., 26 July 1845. He was graduated at McGill University in 1872, and in May of that year joined the staff of the Canadian Geological Survey, of which he later became senior geologist. He is the author of numerous reports on geology and mineral resources, published in the annual volumes of the Canadian Geographical Survey since 1872.

Ells'worth, Ephraim Elmer, American soldier: b. Mechanicsville, N. Y., 23 April 1837; d. Alexandria, Va., 24 May 1861. He organized about 1859 a zouave corps which became noted for the excellence of its discipline. In March 1861 he accompanied President Lincoln to Washington, and in April he went to New York, where he organized a zouave regiment of firemen, of which he became colonel. Ordered to Alexandria, he lowered a Confederate flag floating over a hotel, for which act the hotelkeeper shot him dead.

Ellsworth, Oliver, American jurist: b. Windsor, Conn., 29 April 1745; d. there 26 Nov. 1807. He was graduated at the College of New Jersey in 1766, and soon after commenced the practice of law. In 1777 he was chosen a delegate to the Continental Congress, and in 1780 was elected a member of the council of Connecticut, in which body he continued till 1784, when he was appointed a judge of the superior court. In 1787 he was elected to the convention which framed the Federal Constitution, and was afterward a member of the State convention, where he earnestly advocated the ratification of that important instrument, which his exertions had essentially aided in producing. In 1789 he was chosen a senator of the United States, which station he filled till 1796, when he was nominated by Washington chief justice of the Supreme Court of the United States. In 1799 he was appointed envoy extraordinary to Paris, and with his associates successfully negotiated a treaty with the French. He resigned his office of chief justice in 1800.

Ellsworth, Timothy Edwards, American soldier and politician: b. East Windsor, Conn., September 1836; d. Buffalo, N. Y., 10 Feb. 1904. He was admitted to the bar in 1858, and at the outbreak of the Civil War recruited a company of cavalry, of which he was made captain, and which became a part of the 7th N. Y. cavalry. He practised law at Lockport, and was elected to the State Senate in 1881, 1883, 1895, 1898, and 1900, being at one time speaker *pro tem.* and Republican leader.

Ellsworth, Maine, city, port of entry and county-seat of Hancock County, on both sides of the Union River, and on the Maine C. R.R.; 29 miles southeast of Bangor. It is the trade centre of the county and has extensive timber, ice, ship-building, and fishing interests, exporting over 50,000,000 feet of lumber annually. It has shoe, woolen, leather, and other manufacturing industries, a public high school, custom house, court-house, public library, two national banks, and two weekly newspapers. Pop. (1900) 4,297.

Ell'wanger, George Herman, American author: b. Rochester, N. Y., 10 July 1848. He was educated in Europe and has devoted himself mainly to literature. His published works are: 'The Gardener's Story, or Pleasures and Trials of an Amateur Gardener' (1889); 'The Story of My House' (1891); 'In Gold and Silver' (1892); 'Idyllists of the Country Side' (1896); 'Meditations on Gout, With a Consideration of Its Cure Through the Use of Wine' (1898); 'Love's Demesne, a Garland of Contemporary Love Poems' (edited 1896).

Ell'wood, Thomas, English Quaker: b. Crowell, near Thame, Oxfordshire, 1639; d. Amersham 1 March 1714. About 1660 he was induced to join the Society of Friends, and subsequently became reader to Milton, with whom he improved himself in the learned languages, but was soon obliged to quit London on account of his health. In the year 1665 he procured a lodging for Milton at Chalfont, Bucks, and was the occasion of his writing 'Paradise Regained' by the following observation made on the return of the 'Paradise Lost,' which the poet had lent him to read in manuscript: "Thou hast said much of paradise lost, but what hast thou to say of paradise found?" In 1705 he published the first part of 'Sacred History, or the Historical Parts of the Old Testament'; and in 1709 'Sacred History, etc., of the New Testament.' His other works are numerous; among them 'Davideis, the Life of David, King of Israel, a poem, which is more distinguished for piety than poetry. His life, written by himself, and published the year after his death, affords many interesting particulars of the history of his sect.

Elm, *Ulmus,* a genus of trees and a few shrubs of the natural order *Ulmaceæ.* The species, of which about 20 are known, are natives of the north temperate zone and the southern portions of the Arctic zone. Their southern limits seem to be the Himalayas in Asia and the mountains of southern Mexico. None are natives of the Pacific slope. They are characterized by short petioled, alternate, rough, usually deciduous, leaves with serrate edges; axillary racemes of perfect, apetalous flowers which appear in early spring before or with the leaves; and compressed, winged, dry fruits (nutlets). Many of the species are of wide economic importance. Their hard, heavy, tough, pliable wood is largely used in the manufacture of barrels, agricultural implements, boats, wagon wheels, buildings, etc., and for fuel. The inner bark of some species furnishes an article of food, and that of others a tough bast fibre used for cordage and cloth making. The outer bark of others is used in dyeing and sugar refining. Various parts of several species were formerly popular remedies employed in medicine, but except in domestic and local practice are rarely prescribed. Most of the species are highly valued as ornamental trees in street and park planting, those specially popular being the straight trunked, tall growing, vase-formed species, which quickly over-arch the streets and cast an abundant shade. Many cultivated varieties of fantastic form, color of foliage or habit of growth are also planted as curiosities.

The best-known American species is probably the white, water, or American elm (*U. alba* or *Americana*), which grows in rich moist woods, especially on the shores of streams from Newfoundland to Florida and westward to the eastern side of the Rocky Mountains. It is a tall tree, often attaining a height of 120 feet when growing in the forest, and a wide-spreading, less lofty top when growing in the open, where it may be seen in several different forms, popularly known as vase, plume, oak-tree, etc., according to the arrangement of the branches. Some specimens of each form develop numerous twiggy growths upon the trunk and main branches, which are thus rendered very attractive because of their feathery appearance. The most common form is the vase, in which the main branches develop at about 20 feet or more, and at their bases gradually, and toward their extremities widely diverge. This is probably the most popular street form and species in America. Another well-known American species is the slippery or red elm (*U. fulva* or *rubra*), which attains a height of 70 feet in rich soils and is found from Quebec to Florida and westward to Texas and Dakota. It is called red because the bud scales are reddish and conspicuous when unfolding in spring; and it is called slippery because of its mucilaginous inner bark. Its wood is less valued than that of the English elm, but more than that of the white elm. The cork or rock elm (*U. racemosa*), which grows on river banks from New England to Nebraska and as far south as Kentucky and Tennessee, attains a height of 100 feet and is noted for the corky developments resembling wings on the smaller branches. Its wood is specially valued for its great durability, strength, pliability, and toughness. Another species with corky, winged branches is the Wahoo or winged elm (*U. alata*), which ranges from Virginia to Florida and westward to Texas and Illinois. It rarely exceeds 70 feet in height, is very attractive in habit, and is planted for ornament in the South, but not in the North, as it is not sufficiently hardy for the rigors of winter.

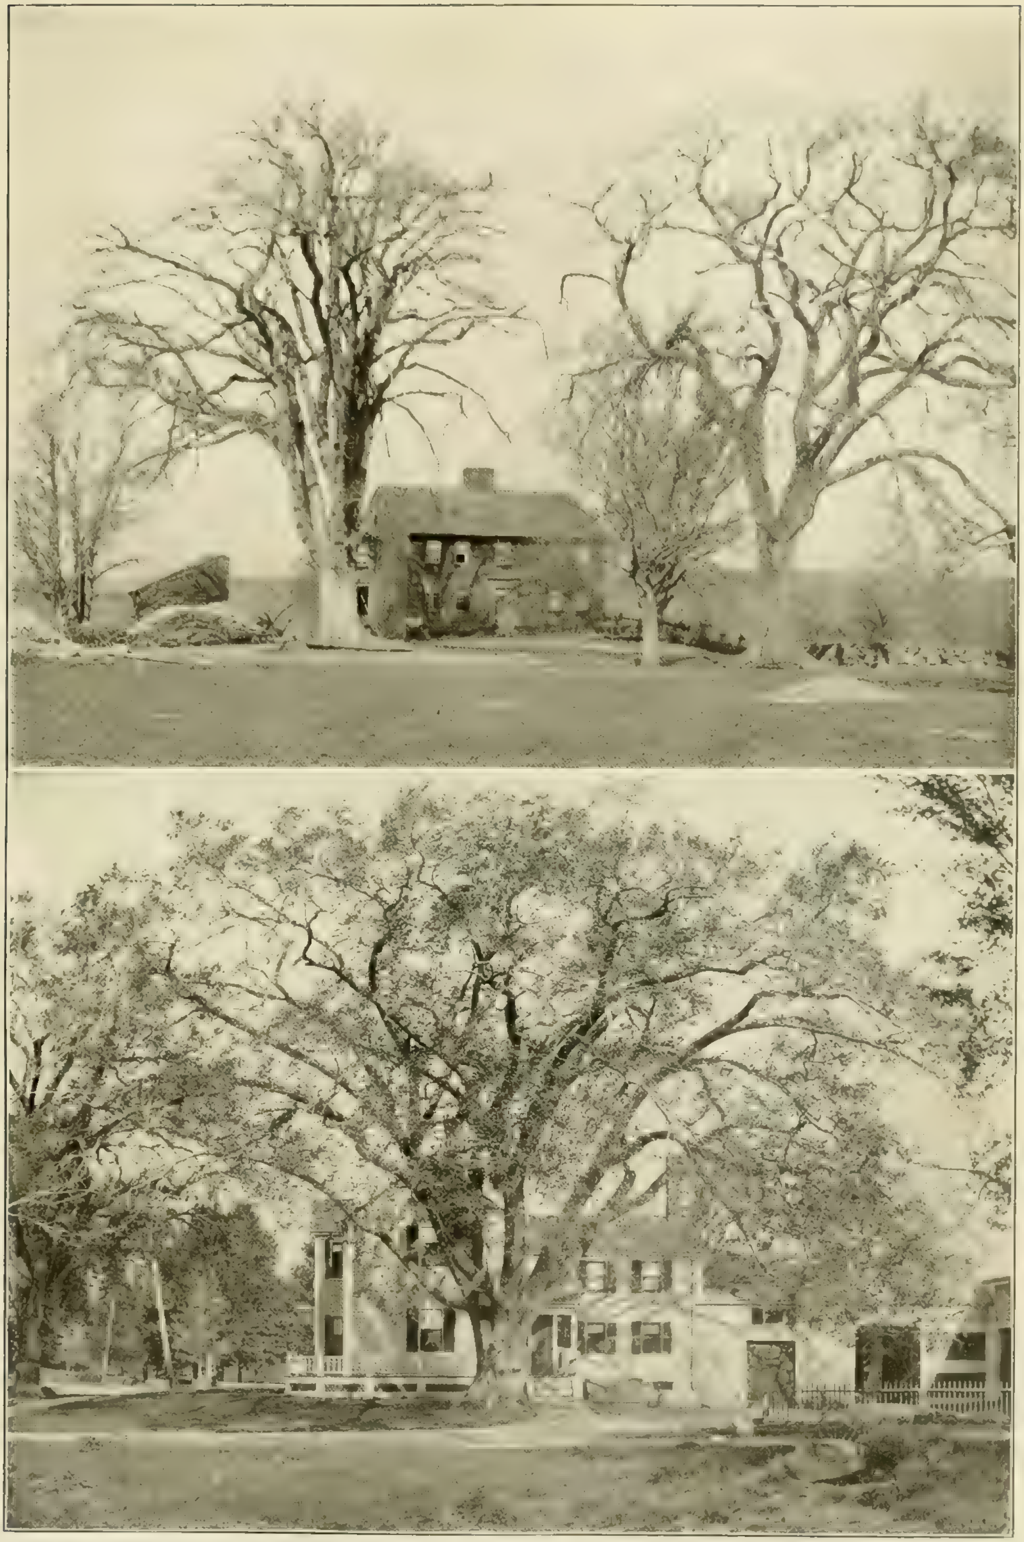
The most noted European species is the English elm (*U. campestris*), which ranges through middle and southern Europe, northern Africa, and eastward to Japan. It reaches 100 feet in height and has a rather round-topped or open head, on account of its spreading branches. It is frequently planted for ornament at home and abroad, and in America is valued because its foliage continues green for several weeks after that of the white elm. It has several distinct varieties, which are sometimes considered as distinct species, and of which there are a large number of horticultural varieties. The next most important European species is probably the Scotch or wych elm (*U. scabra* or *montana*), which has much the same range as the preceding species, like which it attains a height of about 100 feet. It is a variable species with many cultivated varieties, one of the best known of which is the Camperdown elm, which has long, pendulous branches, on account of which the tree is frequently planted as a curiosity in parks and gardens. The Chinese elm (*U. parvifolia*) is a semi-evergreen shrub or small tree, a native of eastern Asia, which has proved hardy in America as far north as Massachusetts.

Elms are readily propagated from seed which ripens in late spring or early summer and should be sown at once. The seedlings are easily managed, both as to cultivation, transplanting and pruning. The trees do best in rich soil, especially if moist. The choice varieties are generally grafted. The trees, especially of the American or white elm, are specially liable to the attacks of certain insects and diseases, which often defoliate them. The latter may be kept in check by the timely and proper application of a standard fungicide (q.v.).

The name elm is also given to various unrelated trees, the best known of which are probably the following: Water elm (*Phanera aquatica*); Spanish elm or Bois-de-Chypre (*Cordia gerascanthus*), and also to *Hamelia ventricosa*, both of which species are natives of the West Indies. Several Australian trees are also known as elms, especially *Duboisia myoporoides* and *Aphananthe Philippinensis*, each of which is valued for its timber.

Elm, Slippery, in medicine, the bark of *Ulmus fulva*, is widely used as a demulcent. It is probable that the ancient Indian inhabitants of the country introduced it into modern medicine. Slippery elm bark is noted for the large amount of mucilage which it contains, thus rendering it a pleasing demulcent for sore throat, diarrhœa, dysentery, and inflammation of the intestinal tract in general.

Elm-insects. Few ornamental trees are more subject to the attacks of insects than are the elms, and especially the American elm. The European species are, however, attractive to the European insects, of which many have been brought over unintentionally, and have spread remarkably because of the absence of their enemies. One of the most notable is the plant-louse known as *Colopha ulmicola*, which produces the cockscomb galls upon the foliage. It is rarely very troublesome, and has usually done its damage before it can be attacked. Kerosene emulsion, if applied in time, will prove



FAMOUS NEW ENGLAND ELMS.

effective. (See INSECTICIDE.) A borer (*Saperda tridentata*) is sometimes troublesome, but there seems to be no satisfactory way to control it. Most of the other insects that attack the elms are beetles, their larvæ, or the caterpillars of various moths. These all bite their food, and hence may be attacked with arsenites or other stomach poisons sprayed upon the foliage. Among these insects are the four-horned sphinx-moth (*Ceratomia amyntor* or *quadricornis*), a green caterpillar with four little horns near the head and the long anal horn characteristic of the sphinx-moth. The bag-worm (*Thyridopteryx ephemeræformis*), the gypsy-moth (*Ocneria dispar*), the tussock-moth (*Notolophus* or *Orgyria leucostigma*), and several other general feeders are frequently troublesome. But the most important leaf-eating enemy of the elm is the elm-leaf beetle (*Galeruca xanthomelæna*), a greenish-yellow, two-striped European insect which appears and eats the leaves in spring. The bottle-shaped yellow eggs are laid in rows on the under sides of the leaves, and the hairy, black-spotted, yellow larvæ eat circular holes between the leaf-veins. Spraying with arsenites is effective, but where more than one brood is produced the sprayings must be repeated frequently throughout the summer. Consult Marlatt, 'Elm Leaf Beetle,' Circular 8, Division of Entomology, United States Department of Agriculture.

Elmer, Horace, American naval officer: b. Bridgeton, N. J., 1847; d. Brooklyn, N. Y., 27 April 1898. He entered the navy as acting midshipman in September 1861, and reached the rank of commander in 1885. During the winter of 1897–8 he superintended the construction of naval vessels at Cramp's shipyard in Philadelphia. When it became evident that war with Spain would break out, he was ordered to organize the naval force afterward known as the "mosquito fleet" for coast patrol duty.

Elmina, ĕl-mē'nä, or **St. George del Mina,** West Africa, a town belonging to Great Britain, formerly the capital of the Dutch settlements on the Gold Coast, five or six miles west of Cape Coast Castle. The Castle of Saint George del Mina was the first European establishment on the coast of Guinea, having been erected by the Portuguese in 1481. Pop. 10,530.

Elmi'ra, N. Y., city, county-seat of Chemung County, on both sides of the Chemung River, and on the Delaware and Lackawanna, the Lehigh Valley, the Northern Central, and the Erie railways; 100 miles southeast of Rochester, 149 miles east-southeast of Buffalo, and 46 miles south-southwest of Ithaca.

Industries, etc.—The government census for 1900 records a total of 362 industrial establishments, with a capital of $7,365,534, the average number of wage-earners being 4,914, with total wages of $1,965,056. Among the more important establishments are railway car and general construction and repair shops, steel-plate works, boot and shoe manufactories, glass works rolling-mills, fire-engine construction works, boiler and engine shops, lumber and planing mills, sash, door and blind factories, breweries, tobacco warehouses and factories of tobacco products, iron and steel bridge works, dye-works, silk-mills, knitting-mills, and hardwood-finishing works. The district is fertile, and there are also stone-quarries in the vicinity.

Public Institutions, Buildings, etc.— Here are located Elmira College (q.v.), a State armory, the State reformatory (see ELMIRA REFORMATORY), the Arnot-Ogden Memorial Hospital, the Steele Memorial Free Library, a Federal government building housing the Federal courts, the post-office, etc., and various charitable institutions. The park system includes Wisner, Riverside, Eldridge, and Hoffman parks. Elmira is finely laid out, and has an excellent water supply, and gas and electric lighting.

History, Government etc.— Elmira was permanently settled in 1788, was incorporated as the village of Newtown in 1815, and in 1828 was re-incorporated as the village of Elmira. In 1836 it became the county-seat of Chemung County, and in 1864 obtained its city charter. During the Civil War it was the State recruiting and military rendezvous, and in 1864–5 one of the Federal prisons for Confederate prisoners of war was here situated. Near the present site of Elmira the battle of Newtown was fought, 29 Aug. 1779. General Sullivan, with an American force numbering 5,000, defeating a combined band of Tories and Indians commanded respectively by Sir John Johnson and Joseph Brant (Thayendanegea) and numbering approximately 1,500. The battle-ground is now marked by a memorial to Sullivan. Elmira is governed, under a charter of 1894, by a mayor, who is biennially elected, and a common council, which is unicameral. In addition to the aldermen, who are chosen by wards for terms of two years, the recorder, municipal judge, and 12 supervisors, to act as a county board, are also chosen by popular vote. Pop. (1890) 30,893; (1900) 35,672; (1903 est.) 37,106.

Elmira, Battle of, 29 Aug. 1779, in the Revolution. See CHEMUNG, BATTLE OF.

Elmira College, an institution for women, located in Elmira, N. Y. It was founded in 1855 under the auspices of the Presbyterian Church, and its course of study from the first demanded as high a grade of work as is usual in first-class colleges. The degrees conferred are bachelor of arts, bachelor of science, bachelor of music, and master of arts.

Elmira Reformatory, a State institution, located in Elmira, N. Y. It is a reformatory to which may be sent only men between the ages of 16 and 30 who have not served a period in a State prison. The court of the State of New York, in sentencing a prisoner to this institution, has no authority to limit the time; that is determined by the managers of the institution, and is almost wholly dependent upon the conduct of the prisoner. However, the term of imprisonment shall not, according to the law of the State, "exceed the maximum term provided by law for the crime for which the prisoner was convicted and sentenced." This reformatory, which takes the place of a State prison for male offenders who have not become hardened in crime, has effected a radical change in methods of dealing with the class of law-breakers intended to benefit. (See BROCKWAY, Z. R.) Consult: Winter, 'The Elmira Reformatory'; New York State Laws of 1877, sec. 2, ch. 173.

Elmo, Ermo, or Erasmus, Saint, a martyr who suffered death at Formiæ, a town of ancient Italy, during the persecution under Diocletian, in 303. He is considered the patron saint of sailors, and is usually invoked by Italian sailors during a storm. His feast is kept on June 3.

Elmo's Fire, Saint, is the popular name of an electric appearance sometimes seen, especially in southern climates during thunderstorms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is also observed at the tops of trees, on the manes of horses, and occasionally about human heads. It is similar in kind to the luminous glow seen at the point when a lightning-rod is working imperfectly, or when there is any very rapid production of electricity. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux, and was regarded as of friendly omen. The name Elmo is by many thought to be a corruption of that of Helena, the sister of Castor and Pollux. Others take it to be a corruption of Saint Erasmus (Italianized, *Ermo, Elmo*), a Syrian bishop and martyr of the 3rd century, who is invoked by Mediterranean sailors during storms. The phenomenon has also been called the fire of Saint Elias, of Saint Clara, of Saint Nicholas, and of Helena, as well as composite, composant or corposant (that is, *corpus sanctum*).

El'more, Alfred, Irish artist: b. Clonakilty, Ireland, 18 June 1815; d. London 24 Jan. 1881. He studied at Royal Academy, London, traveled through Europe to Rome, where he lived two years, returned to England 1844, becoming an associate of the Royal Academy 1845, and Royal Academician 1856. Among his works are: 'Martyrdom of Thomas à Becket' (1840), St. Andrew's Church, Dublin; 'The Novice' (1843); 'Rienzi' (1844); 'Death of Robert, King of Naples' (1848); 'Griselda' (1850); 'Charles V. at Yuste' (1856); 'Marie Antoinette in the Temple' (1861); 'Louis XIII. and Louis XIV.' (1870); 'Ophelia' (1875); 'Mary Queen of Scots and Darnley' (1877); 'Pompeii,' 'John Alden and Priscilla' (1878); 'After the Ruin,' and 'Lenore.'

Elms, City of, a popular name given to New Haven, Conn.

Elmshorn, ĕlmz'hôrn, Germany, town in Sleswick-Holstein, 20 miles northwest of Hamburg, on the railway to Kiel, and on the Krückau, a navigable tributary of the Elbe. It carries on a considerable amount of traffic by land and water, and has manufacturing industries of various kinds, such as leather, boots and shoes, machinery, dyeing, linen- and cotton-weaving, distilling and brewing, etc. Pop. 13,720.

Elobey (a-lō-bā'ē) **Islands,** the name of two small islands off the coast of Guinea, in Africa, both of which belong to Spain. On Elobey Chico, the smaller island, there is a missionary school, and some manufacturing has been begun. Elobey Grande is the larger island. Pop. of both (1901) 350.

Elocution, the art of correct speaking or reading in public, including the appropriate use of gestures. Great attention was paid by the ancients to this art as a branch of oratory. The rhetors in Greece had schools in which young men were trained in the correct use of the voice. Many of the Romans were sent to Greece to study and afterward there were similar teachers of elocution and oratory in Rome. In modern times the stage has fostered the study of elocution and special attention has been given to it in the Paris Conservatoire, where the strictest canons of the art have been maintained. Many colleges have established professorships of elocution, and it is also one of the branches in the curriculum of well-regulated conservatories of music. The tendency of modern teachers is toward greater simplicity and naturalness of gesture and repose of manner than was formerly used. Perhaps the most successful teacher of this century was Delsarte (q.v.), whose theories and practice worked a revolution both in France and other countries. Notable schools of elocution have been established in this country by Charles Wesley Emerson, Franklin H. Sargent, and others. The list of distinguished elocutionists includes the names of Munroe, Riddle, Riley, Powers, and Mackaye. See ORATORY.

Eloge, ā-lōzh (French), is a discourse pronounced in public in honor of the memory of an illustrious person recently deceased. In modern times the éloge is peculiarly a French institution, and has given rise to a quite distinct species of literature, which, though its style is not the most agreeable, is not altogether without utility, as the best éloges frequently contain rapid and summary views of the state of science, art, literature at a particular time, of the works of some distinguished author, the political events of a period, or whatever other theme may be suggested to the orator by the particular career of the subject of his eulogy. The éloges of Fontenelle (1731), and of Cuvier (1819), are particularly valuable and interesting. Such summaries, of course, considering the object with which they are made, must be received with great caution, but they frequently convey information not easily accessible in other ways. An éloge is pronounced over every member of the French Academy when he dies, as the inaugural discourse of the new member who is chosen to succeed him. The abuses to which this style of composition is liable have given rise to burlesque and satirical éloges.

Elohim, ĕl'ō-hĭm or ē-lō'hĭm (plural of Eloah), one of the Hebrew names for God, of frequent occurrence in the Bible, especially in those parts of the Pentateuch attributed to the earliest writers in the northern domain of the Semitic race. Elohim is used in speaking both of the true God and of false gods, while Jehovah is confined to the true God. The plural form of Elohim (literally signifying "the great Eloah" or God) has caused a good deal of controversy among critics. By some it has been considered as containing an allusion to the doctrine of the Trinity, others regard it as the plural of excellence, while others hold it as establishing the fact of a primitive polytheism. This word, along with Jehovah, has played a great part in modern criticism. Critics have professed to find in the comparative frequency of the two terms an evidence of the date of the manuscripts in which they occur; but on this controversy we cannot enter. See ELOHIST.

Elohist, ĕl'ō-hĭst, also called **Yahwist,** both used in contradistincton to Jehovist (q.v.), one of the Biblical writers, hypothetically assumed to have written part of the Pentateuch, who habitually, if not exclusively, used **the**

Hebrew name Elohim for God. The Elohistic passages in the Old Testament, as determined upon by Biblical scholars, are simple, straightforward, and bear no signs of rhetoric or poetic effort, therein contrasting with the Jehovistic paragraphs. Gen. i. 27 is Elohistic; Gen. ii. 21-4 is Jehovistic. See BIBLE.

Elonga'tion, in astronomy, the angle that measures the apparent distance of two stars as seen from the earth. The term is, however, by usage confined exclusively to the distance of a planet from the sun, and of a satellite from its primary. The greatest elongation of Mercury amounts to about 28° 30′; that of Venus to about 47° 48′, and that of the superior planets may have any value up to 180°. When two fixed stars or planets are spoken of the word «distance» is employed.

Elopement, an act of unlicensed departure, especially when a wife forsakes her husband and flees with a paramour, or when a daughter or ward accepting the protection of a lover leaves her natural or legal guardians. In almost every one of the States, the male principal in an elopement is held guilty of an abduction provided his associate in the act is under age. Marriage, however, checks all consequent criminal proceedings unless the female alleges coercion. All persons guilty of aiding or abetting an elopement of a male with a female are deemed in law accessories, and liable to legal proceedings. Elopers themselves are not safe from arrest, their act coming within the purview of the criminal statutes.

Elothe'rium, an extinct suilline animal of the Oligocene Epoch, remotely related to the hippopotami and pigs. The skull suggests that of the hippopotamus, but it has a narrow elongated muzzle; and the front teeth resemble those of the carnivora rather than the shearing tusks of the hippopotami and pigs. The limbs and feet are tall and stilted, the lateral toes reduced to small rudiments, as in ruminants. Different species ranged in size from that of a sheep to that of a rhinoceros.

El Petén, Guatemala, one of the northern departments of the republic; pop. 6,752. Its chief town is Flores; pop. 1,671, and altitude above sea 482 feet.

El'phinstone, Mountstuart, East Indian administrator: b. Scotland 6 Oct. 1779; d. Limpsfield, Surrey, 20 Nov. 1859. He joined the Bengal civil service in 1795; was ambassador to the Afghan court in 1808; resident at the court of Poonah from 1810 to 1817; and British commissioner to that province from 1817 to 1819, when he became governor of Bombay. During a government of seven years he established a code of laws, lightened taxes, and paid great attention to schools and public institutions. He resigned in 1827. A college established by the natives was called after him Elphinstone College. He was the author of an 'Account of the Kingdom of Cabul and Its Dependencies' (1815); and a 'History of India' (1841).

Elphinstone, William, Scottish prelate: b. Glasgow 1431; d. 25 Oct. 1514. Having gone to France he studied law for three years, and was appointed professor of law, first at Paris and subsequently at Orleans. He was subsequently made commissary of the Lothians, and in 1479 was made archdeacon of Argyle. Soon after he was made bishop of Ross; and in 1483 was transferred to the see of Aberdeen. In 1488 he was made lord high-chancellor of the kingdom, In October of that year he assisted in the coronation of James IV. He was afterward sent on a mission to Germany, and on his return was installed in the office of lord privy-seal, which he held till his death. In 1494 he obtained a papal bull for the erection of a university at Aberdeen, and King's College and University soon came into existence.

El Quicke, Guatemala, one of the northern departments of the republic; pop. 92,753. Its chief town is Santa Cruz; pop. about 12,000 and altitude above sea-level 5,543 feet.

Elsberg, ĕlz'bĕrg, **Louis,** German-American physician: b. Gerlohn, Prussia, 1836; d. in the United States in 1885. He introduced the art of laryngoscopy in the United States, wrote many papers on the throat and its diseases, notably, 'The Throat and the Production of the Voice'; was the first to illustrate the character of undertones and divisions of sound in articulation, and invented many instruments which are used in surgical treatment of the throat and ear.

Elsheimer, ĕlz'hīm-ĕr, **Adam,** German painter: b. Frankfort-on-the-Main 1578; d. probably at Rome 1620, called the «Roman Painter of Germany.» He studied in Rome and settled there while still very young. He painted many biblical and mythological scenes and was a master of landscape, being the chief German artist of the end of the 16th century to acclimatize Roman art in Germany. Among his principal works are: 'Jupiter and Mercury with Philimon and Baucis'; 'Joseph in the Pit'; and 'Judith,' at Dresden; 'Martyrdom of St. Lawrence,' and 'Flight into Egypt,' at Munich; his portrait and 'Triumph of Psyche' at Florence; many landscapes at Naples, Venice, and Madrid; 'Good Samaritan,' and another 'Flight into Egypt' at the Louvre, and a large collection of drawings.

Elsie Venner, a romance by Oliver Wendell Holmes, first published serially, in 1859-60, under the name of 'The Professor's Story.' It is a study in heredity, introducing a peculiar series of phenomena closely allied to such dualism of nature as may best be described by the word «ophianthropy.» Delineations of the characters, social functions, and religious peculiarities of a New England village, form a setting for the story. The victim of some pre-natal casualty, Elsie shows from infancy unmistakable traces of a serpent-nature intermingling with her higher self. This nature dies within her only when she yields to an absorbing love.

Elsinore, ĕl-sĭ-nōr', or **Elsineur** (Danish, Helsingör), Denmark; seaport, on the island of Zealand; 24 miles northeast of Copenhagen. Its inhabitants are engaged chiefly in commerce and seafaring. The castle of Kronborg, built about 1580, is the chief defense of the town. It is a Gothic-Byzantine edifice, built by Frederick II in the boldest style, and is said to be one of the finest structures of its kind in Europe. It is now chiefly used as a prison, and was the place of confinement of the unfortunate Matilda, sister of George III. of England. The manufactures are chiefly fishing-nets and a coarse cloth. Ship-building has been an important industry. Pop. (1901) 13,902.

Elson, Henry William, American author: b. Muskingum County, Ohio, 29 March, 1857. He was educated at Lutheran Theological Seminary, Philadelphia, and the University of Pennsylvania. After occupying two or three Lutheran pastorates he left the ministry and took up the work of writer and lecturer of the University Extension Society of Philadelphia. He has published 'Side Lights on American History' (1899); 'Four Historical Biographies for Children: Andrew Jackson, U. S. Grant, Daniel Boone, and Frances Willard' (1899); 'How to Teach History' (1901), and 'Elson's History of the United States.'

Elson, Louis Charles, American writer on music: b. Boston, Mass., 17 April 1848. After studying music at Leipsic he returned to Boston and has been a teacher and lecturer on music there from 1876. He has been musical editor of the Boston *Advertiser* since 1888. He has published 'Curiosities of Music' (1883); 'German Songs and Song Writers' (1886); 'Our National Music and Its Sources' (1886); 'Theory of Music' (1890); 'Realm of Music' (1892); 'European Reminiscences' (1893); 'Great Composers' (1897); 'Shakespeare in Music' (1900); 'Famous Composers and Their Works,' new series (1901).

Elssler, ĕlz'lėr, **Fanny,** Austrian dancer: b. Vienna 23 June 1810; d. there 27 Nov. 1884. She was the daughter of Johann Elssler, Haydn's factotum, and was educated at Naples for the ballet, with her elder sister Theresa, who in 1851 became the morganatic wife of Prince Adalbert of Prussia and was ennobled. Fanny Elssler during her visit to the United States gave an entertainment in order to raise money for the Bunker Hill Monument.

Elster, ĕl'stĕr, two German rivers. (1) The White, or Great Elster, rising in the west of Bohemia, flows north into Saxony, receives the Pleisse and Parde at Leipsic, and joins the Saale between Halle and Merseburg, after a course of about 115 miles. (2) The Black Elster, rising in Saxony, flows north into Prussia, then northwest, receives the Pulsnitz and Röder, and joins the Elbe between Wittenberg and Torgau, after a course of about 130 miles.

Els'tracke, Reginald or **Ronald,** English engraver: b. probably in London and lived there early in the 17th century. His plates were made with the graver solely, their chief value being historical. He executed portraits of Mary Queen of Scots, Darnley, and Queen Elizabeth. Among his works was a volume of 32 plates called 'Basiliologia: a Book of Kings, being the true and lively effigies of all our English Kings from the Conquest until this present' (1618).

Elswick, ĕlz'wĭk, England, suburb of Newcastle, containing the great ordnance works of Sir William Armstrong, Mitchell & Company. These works are probably the largest of their kind in Europe, and employ about 14,000 persons. Pop. 51,000.

El'ton, Charles Isaac, English jurist and archæologist: b. Somerset 1839; d. Chard, Somerset, 23 April 1900. He was educated at Oxford and was called to the bar in 1865. He represented West Somerset in Parliament as a Conservative 1884–5 and 1886–92. On legal subjects he published: 'Tenures of Kent' (1867); 'Commons and Waste Lands' (1868); 'Copyholds and Customary Tenures' (1874–93); 'Improvement of Commons Bill' (1876); 'Custom and Tenant-Right' (1882); and 'Robinson on Gavelkind' (1897). Other works of his are: 'Norway, The Road and Fell' (1864); 'The Career of Columbus' (1892); 'The Great Book-Collectors' (1893); and 'Shelley's Visits to France' (1894). His greatest work, however, is his 'Origins of English History' (1882). It is chiefly characterized by its thorough investigation of the evidence furnished by Greek and Roman writers regarding the condition and circumstances of early Britain, by its discussion of the ethnology and prehistoric archæology of the country, and by the importance assigned to the Celtic and even pre-Celtic element in forming the English nation.

Elton, James Frederick, English explorer: b. 3 Aug. 1840; d. 13 Dec. 1877. He entered the Indian Army in 1857. In 1871 he found himself in the Transvaal and Natal; in 1873 he was vice-consul at Zanzibar, two years afterward as consul in Mozambique he explored the coast of East Africa for the sake of repressing the slave trade. With Cotterill he reached Lake Nyassa in 1877 and scaled the Konde range of mountains at the north end of the lake, to the height of 10,000 feet. After his death Cotterill published his journal under the title: 'Travels and Researches among the Lakes and Mountains of Eastern and Central Africa.'

Elton, a shallow lake in the government of Astrakhan, in Russia; area, 60 square miles. Eight salt-water streams flow into this lake, and it has no visible outlet; thus a large salt deposit rests on the bed of the lake. From about the middle of the 17th century for 100 years, the salt from this lake was in demand; but since the opening of the salt fields in the southern part of Russia (1860) the Elton salt has not been on the market.

Elvas, āl'väs (Rom., Alpesa; Moorish, Balesh), the strongest fortified city of Portugal, in the province of Alemtejo, near the Spanish frontier; 10 miles west of Badajoz. Standing on a hill, it is defended by seven large bastions and two isolated forts. Pop. (1900) 14,018.

Elves (O. Eng., œlf; Germ. Alp; phantom, spirit); imaginary creatures of the northern mythology, forming, according to some classifications, with the undines, salamanders, and gnomes, groups of elementary sprites identified respectively with the water, fire, earth, and air. The elves are of the air, and have been more widely received in the faith and poetry of Europe under this name than under that of sylphs, invented by Paracelsus. They are capricious spirits, of diminutive size but preternatural power. Their stature is less than the size of a young girl's thumb, yet their limbs are most delicately formed, and when they will they can hurl granite blocks, bind the strongest man, or shake a house. They are divided in the sagas into good and bad, or light and dark elves, the former having eyes like the stars, countenances brighter than the sun, and golden yellow hair, the latter being blacker than pitch, and fearfully dangerous. The elves ordinarily wear glass shoes, and a cap with a little bell hanging from it. Whoever finds one of these slippers or bells may obtain from the elf who has lost it any thing which he asks for. In the winter they retire to the depths of mountains, where they live in much the same way as men, and in the first days of spring issue from their grottoes, run along the sides of hills, and swing upon the branches of the trees. In the morning they sleep in blossoms or watch the people who pass by, but at the evening twilight they meet together in the fields, join hands, and sing and dance by the light of the moon. They are generally invisible, but children born on Sunday can see them, and the elves may extend the privilege to whomsoever they please. In England and Scotland they became fairies in the former, and brownies in the latter country, and were subject to a king and queen. The islands of Stern and Rugen, in the Baltic, are especially subject to the king of the elves, who rides in a chariot drawn by four black horses, and whose passage from island to island is recognized by the neighing of the steeds, the blackness of the water, and the bustle of the great aërial company who follow in his train. The elves sometimes become domestic servants, and would be valuable as such if they were less easily offended and less dangerous after taking offense. As long as their caprices are gratified, their food and drink regularly left at an appointed place, and no attempt made to interfere with their freedom, the furniture is sure to be dusted, the floor to be swept, and every chamber to be perfectly in order. But the brothers Grimm, in their 'Deutsche Sagen,' have chronicled the misfortunes of many a young girl, who, having called an elf to her aid, repented too late of having offended it.

El'well, Frank Edwin, American sculptor: b. Concord, Mass., 15 June 1858. He studied at the Ecole des Beaux Arts, Paris, and also under Jean Alexandre Falguiere, and is a member of the Institute of France. Among his works are a monument at Edam, Holland, 'Death of Strength'; statue in Paris of 'Awakening of Egypt'; equestrian statue of Gen. Hancock at Gettysburg; monument to Edwin Booth, Mount Auburn, Cambridge; the two fountains of 'Kronos' and 'Ceres' at the Pan-American Exposition, Buffalo; 'Dickens and Little Nell,' Fairmount Park, Philadelphia; and a bust of Levi P. Morton, Senate chamber, Washington.

Elwell, James William, American philanthropist: b. Bath, Me., 27 Aug. 1820; d. Brooklyn, N. Y., 2 Sept. 1899. He became a partner in his father's commission-house in New York in 1838; and after the death of his father founded the firm of James W. Elwell & Company in 1852. The firm owned three lines of vessels to the principal European, southern, West Indian and South American ports. His philanthropic gifts aggregated $3,000,000, and he bequeathed $25,000 to his favorite charities. He originated the Helping Hand Society and was one of the founders of the Brooklyn Orphan Asylum. He was also identified as trustee or director with many other charitable institutions.

El'wood, Ind., city in Madison County; on the Pittsburg, C., C. & St. L., and the Lake Erie & W. R.R.'s; about 50 miles northeast of Indianapolis. It is surrounded by an agricultural region, and is in a natural-gas belt. Its industries are chiefly lumber, flour, tin-plate-mills; window, plate glass and lamp chimney and other factories. Its shipping trade consists in the agricultural products of the surrounding country, and the articles manufactured in the city. Pop. 12,950.

Ely, Richard Theodore, American political economist: b. Ripley, N. Y., 13 April 1854. He was graduated from Columbia University in 1876, and studied also at Heidelberg, Germany. He became professor of political economy at Johns Hopkins University in 1881, and professor of political economy and director of the school of economics and political science at the University of Wisconsin in 1892. On account of his advocacy of trade unions, he was accused in 1894 of "aiding and abetting" a strike, and of being a Socialist, and an attempt was made to force him out of his professorship at the university. A committee of the regents appointed to investigate the matter acquitted him. While he is not a Socialist, he advocates public ownership of "natural monopolies" and has carefully investigated and stated the aims of the Socialist movement. His works include: 'French and German Socialism in Modern Times' (1883); 'Socialism and Social Reform' (1894); 'Recent American Socialism' (Johns Hopkins University Studies, Vol. III., 1885); 'Problems of To-Day' (1886); 'The Labor Movement in America' (1886); 'Political Economy' (1889); 'Social Aspects of Christianity' (1889); 'Social Law of Service' (1900); 'Monopolies and Trusts' (1900). This last is a small part of a large work, 'The Distribution of Wealth,' which is not completed.

Ely, England, an episcopal city, in the county of Cambridge; about 15 miles northeast of Cambridge; on the Ouse. The place is noted for its cathedral, one of the most remarkable edifices of the kind in England. It occupies the site of a monastery founded about the year 673 by Saint Etheldreda (or Audry), daughter of Anna, king of East Anglia. Its ancient history is most interesting. In 1071, Hereward, the noted English outlaw, defended Ely against the Normans. See HEREWARD. Pop. 7,812. Consult: Van Rensselaer, 'English Cathedrals'; F. Bond, 'English Cathedrals'; Stewart, 'Architectural History of Ely Cathedral.'

Ely, Isle of, a district in England, in the county of Cambridge, separated on the south by the Ouse from the remaining portion of the county, and forming itself a sort of county; area 227,326 acres. It rises about 100 feet above the general level of the fen country, and was formerly surrounded by marshes, which at times became sheets of water. The whole has by drainage been converted into fertile fields. Pop. (1901) 64,494.

Elymais, ĕl-ĭ-mā'ĭs. See ELAM.

Elyot, ĕl'ĭ-ŏt, SIR **Thomas,** English author: b. Wiltshire not later than 1490; d. Carlton, Cambridgeshire, 20 March 1546. In 1511 he became clerk of assize, in 1523 clerk of the king's council. In 1531–2, as ambassador to Charles V., he visited the Low Countries and Germany, having orders to procure, if possible, the arrest of Tyndale. 'The Boke named the Gouernour, deuised by Sir Thomas Elyot, Knight,' was published in 1531. It may be described as the earliest treatise on moral philosophy in the English language, the author's principal object being "to instruct men in such vertues as shall be expedient for them which shall have authoritie in a weale publike." An elaborate 10th edition appeared in 1880, with life notes and glossary by H. H. S. Croft. Elyot's 12 other works include: 'Of the Knowledge which maketh a Wise Man' (1533); 'Pasquil the Playne' (1533); Isocrates' 'Doctrinal of Princes' (1534); Picus de Mirandola's 'Rules of a Christian Lyfe' (1534); 'The Castel of Helth' (1534); 'The Bankette of Sapience' (1534); 'Bibliotheca' (1538), the first Latin-English dictionary; 'The Image of Governance' (1540); 'Defence of Good Women' (1545); and 'Preservative against Deth' (1545). These books went through edition after edition in their author's lifetime, and have now become among the rarest treasures of the bibliomaniac.

Elyr'ia, Ohio, city, county-seat of Lorain County; on the Black River; and on the Cleveland, L. & W., and the Lake Shore & M. S. R.R.'s; 25 miles southwest of Cleveland. Agriculture is the chief industry of the surrounding country; the sandstone quarries furnish employment to a number of people. The chief manufactures in the city are supplies for automobiles and bicycles, saddles, and iron and steel products. Pop. 8,112.

Elysée, Palais de l', pă-lā dė lā-lē-zā, the official residence of the president of France, in Paris, on the Rue du Fauburg St. Honore, with its garden extending to the Champs Elysees. It was built in 1718 for the Count d'Evreux; in the reign of Louis XV. it became state property, and was the residence of Madame de Pompadour. It was also used as a residence by Napoleon I., and by Louis Napoleon, and became the presidential residence in 1871.

Elys'ian Fields, or **Elysium,** in classical mythology, the residence of the blessed after death. Elysium was supposed by Homer to have been at the western end of the earth; other poets placed it in the Fortunate Isles; later it was supposed to be in the under world. It was represented as a region of perfect happiness, where the sky was always cloudless, and a celestial light shed a magic brilliancy over every object; where each one was free to follow his favorite pursuit, and cares and infirmities were unknown.

Elze, ĕl'tsĕ, **Karl,** German historian of literature: b. Dessau 22 May 1821; d. Halle 22 Jan. 1889. His specialty was English literature, and he was professor of English philology in the University of Halle 1875–89. One of his first works was a compilation entitled a 'Treasury of English Song.' He produced critical editions of Shakespeare and other English dramatists, and wrote biographies of Byron and other English authors. Specially noteworthy is his 'Outline of English Philology.' 'Westward' (1860) contains translations of English and American poems.

Elzevir, ĕl'zĕ vĭr, name of a notable family of printers descended from Ludovic Elsevier or Elzevier, Latinized Elzeverius, a native of Louvain: b. 1540. Having learned the bookbinders' trade, he practised it for some years in his native town, but 1580 he removed to Leyden in the United Provinces, and there set up a printing press. His five sons, Matthew, Ludovic, Egidy, Joost, and Bonaventura, were also printers and booksellers; but it was the youngest of the five, Bonaventura, born 1583 at Leyden, that gave the name Elzevir its great celebrity. The first work published by the house of Elzevir appeared in 1583, the 'Ebraicæ Quæstiones et Responsiones' of Drusius, not the whole three books, but only the second and third. In 1608, nine years before his father's death, Bonaventura Elzevir founded a separate printing and publishing establishment in the same city, and then commenced the issue of works in Greek, Latin, and other languages which have ever since been regarded as models of correct and elegant typography. He conducted the business of his house more than 42 years, till his death in 1652, having had as partner from 1626 Abraham Elzevir, his nephew, whom he survived one month. He was succeeded by his son Daniel and Abraham's son John: this partnership was soon dissolved, John carrying on the business in Leyden, Daniel migrating to Amsterdam in 1655 and entering into partnership there with another of his cousins: both of these were dead 1680. The last of the Elzevirs to figure in the history of typography was Abraham, son of Abraham, one of the five sons of Ludovicus: from 1681 to 1712 he was printer to the University of Leyden. The Elzevir editions of the ancient classics, especially Latin, while admirable in point of typography, are mostly reproductions of the texts adopted by previous printers and hence are inferior from the critical point of view. The number of works published by the different Elzevir houses number 1,213, namely, Latin 968; Greek 44; French 126; Flemish 32; Oriental 22; German 11; Italian 10.

Emancipation, the act by which freedom of various kinds is granted to individuals, races, or nations. In Roman law the dissolution of paternal authority (*patria potestas*) in the lifetime of the father. It took place in the form of a sale by the father of the son to a third party, who manumitted him. The Twelve Tables, the foundation of Roman law, required that this ceremony should be gone through three times. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a patron which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren one sale was sufficient. The Catholic Emancipation Act was the act signed 13 April 1829, which removed the most galling of the Roman Catholic disabilities in England. See CATHOLIC EMANCIPATION; EMANCIPATION PROCLAMATION; SLAVERY.

Emancipation, Catholic, the customary designation of a measure of relief from penalties and civil disabilities granted to professors of the Catholic religion in England and Ireland by acts of the British Parliament 1829: the act did not extend to Scotland. The necessity of granting relief to the Catholics of Ireland became apparent soon after the outbreak of the war against the American colonies, and the first relaxation of the penal laws against the professors of the Catholic religion was made in 1780. At that time it was high treason for a priest, native of the kingdom, to perform any of the duties of his office. Catholics could not own land in fee. Roman Catholics whose titles to land antedated the penal laws were ousted if the legal heir professed Protestantism. A Catholic could not practise law, nor conduct a school. In 1780 a bill for removal of some of the disabilities was passed for England and Ireland. When the act of union of the kingdom of Ireland with that of Great Britain was passed in the Irish Parliament 1800, solemn pledges were given by the British Cabinet that the disqualifying statutes should be repealed; but after the union the promise was ignored. In 1824 in Ireland was formed the Catholic Association to agitate for civil rights, such as the right to vote for members of the Parliament, to be elected members of the same, and to occupy various offices in the government, national and local. In 1829 it was seen by English statesmen that to withhold these rights and franchises any longer would provoke a rebellion in Ireland; and a bill of relief was introduced in the Parliament 5 March, and passed in both houses and approved by King George IV. 13 April, permitting Catholics to elect and be elected to the Parliament, and to hold offices under the Crown; but they remained still expressly excluded from certain high offices — that of lieutenant-governor of Ireland, that of regent of the universal kingdom, of lord chancellor of the United Kingdom, or of Ireland, etc. In 1867 the last named disability was removed, as was, many years after, the disability of a Catholic to be lord chancellor of the United Kingdom. But the Act of Grace of 1829 contained a clause forbidding Catholic ecclesiastics, monks, friars, and nuns from wearing the attire or habit of their respective station or order in public under a penalty of $250 for each offense. This proviso was ostentatiously violated in Ireland, and with impunity, for, like the $500 forfeiture for violation of the Ecclesiastical Titles Acts (q.v.), no penalty was ever exacted. Another clause of the Catholic Emancipation Act, which was also ignored and condemned, required that Jesuits and members of religious orders of the Roman Catholic Church living within the kingdom should register in the office of the clerk of the peace of the county under a penalty of $250. See O'CONNELL, DANIEL. Consult: Butler, 'Historical Memoirs'; Milner, 'Supplementary Memoirs'; Lingard, 'History of the Church in England'; Green, 'History of England.'

Emancipation in Latin-America: the Manumission of Slaves in Relation to the several Declarations of Independence. In Haiti, where African slavery was first introduced into America, the negroes received as a gift "the full liberty, equality, and fraternity" of the French republic in 1794, and by fighting established their independence in 1804. In Central America (when Guatemala, Salvador, Honduras, Nicaragua, and Costa Rica were united in the Central American republic), the laws of 31 Dec. 1823 and 17 and 24 April 1824 emancipated all slaves, and made free slaves of other countries coming to Central America. The slave trade was prohibited, under penalty of forfeiture of the rights of citizenship. H. H. Bancroft, in his 'History of the Pacific States,' says: "Of all the nations of North America, to the Central American republic belongs the honor of having first practically abolished slavery." We shall presently show, however, that this distinction fairly belongs to Mexico. Ecuador, which made its first effort to gain independence at Quito, 10 Aug. 1809, and actually threw off the yoke of Spain on 9 Oct. 1820, abolished slavery during the presidential term of Gen. Urvina, 1852–6. The Argentine nation began its struggle for independence 25 May 1810, and at the congress of Tucuman, 9 July 1816, the formal separation from Spain was declared. Article XV. of the Constitution of 25 Sept. 1860 provides that "there shall be no slaves in the Argentine nation. Those few who now exist in it shall become free at the very moment this constitution goes into effect. The indemnifications which this declaration may involve shall be provided for by special law. Any contract involving the purchase or sale of a person shall be held to be a criminal offense. . . . Slaves introduced in any way whatever into the country shall become free by virtue of the fact that they have trodden the soil of the republic." In Colombia (New Granada) the number of negroes was never very great; it was estimated at 80,000 in the middle of the 19th century. The struggle for independence, beginning 20 July 1810, or as a vigorous insurrection in 1811, was continued after the union with Venezuela (December 1819), and the republic of New Granada was formed in 1831. In 1821 a law was pased by the republic of Colombia for the gradual manumission of slaves, and all born after that date were declared free at the age of 18,— that gradual process applying, of course, to all the territory of the Greater Colombia at the time of the law's enactment. (See COLOMBIA, *History*.) A law of 1851 abolished slavery entirely in New Granada, by giving liberty to all who remained slaves on 1 Jan. 1852, provision being made for the payment of indemnity to the owners. The beginning of the war for independence in Mexico dates from 16 Sept. 1810 (see DOLORES, EL GRITO DE); on 6 Nov. 1813 the first Mexican congress, installed in the town of Chilpancingo, issued the declaration of independence and decreed the emancipation of slaves. This, therefore, was the starting point of emancipation on the mainland of America. Venezuela's declaration of independence (5 July 1811) was followed after 10 years by the law for the gradual manumission of slaves which we have mentioned above, that is, the law of the Greater Colombia of 1821. Paraguayan independence should be dated from 11 June 1811, when an assembly of deputies began its sessions; for the resolution passed by this assembly, renouncing allegiance to Spain, was ratified as a declaration of independence by the Paraguayan congress of 1 Oct. 1813. The question of African slavery was comparatively unimportant in Paraguay. "In 1865 there were negroes and mulattoes at Emboscada, Tabapy, and Aregui; but the negroes have now almost completely disappeared" ('Handbook of Paraguay,' September 1902, issued by International Bureau of the American Republics). Chile entered upon a contest with Spain on 18 Sept. 1810, and the independence of the country was proclaimed 12 Feb. 1818. The negro problem did not weigh upon that country, the population being recruited from Europe quite largely. The independence of Peru was declared at Lima 28 July 1821; that of the Dominican republic 1 Dec. 1821; that of Brazil 7 Sept. 1822; and Bolivia became an independent republic 6 Aug. 1825. In Brazil the conservative statesman, Silva Paranhos, obtained from the parliament the passage of a bill (28 Sept. 1871) for the gradual extinction of slavery, which provided that thereafter every child born of a slave mother should be free, and created a special fund for emancipation by redemption. Private philanthropy, largely directed by the Masonic lodges, effected more than the fund created for this purpose; and the number of slaves began to decrease. A bill for the immediate and unconditional abolition of slavery in Brazil was signed by Princess Regent Isabel 13 May 1888; the monarchy was overthrown 15 Nov. 1889; the new Constitution approved 24 Feb. 1891. In Cuba the slaves were emancipated on the conclusion of the Ten Years' War, that is, in 1878, and Cuba became a republic 20 May 1902. The experiences of the French, Danish, and British possessions may be referred to briefly in conclusion. Napoleon restored slavery in French Guiana, Martinique, and Guadeloupe, although his efforts to accomplish the same result in Haiti were, as mentioned above, frustrated by the resistance of the blacks themselves. The freedom of all who were held in bondage throughout the French dominions was declared in 1848. Slavery in the Danish West Indies (St. Thomas, etc.) was abolished also in 1848. The act to abolish slavery throughout the British colonies, providing £20,000,000 for compensation of the owners, was dated 28 Aug. 1833, and its effect was to free 770,280 slaves on 1 Aug. 1834, the number thus emancipated in Jamaica being 309,000.

MARRION WILCOX.

Emancipation Proclamation, 1 Jan. 1863. The Republican administration at the outbreak of the Civil War was awkwardly placed for dealing with slavery. To assail it in its own territory was not only to belie the past professions of the party, but to alienate so much Northern support as to assure failure; nor indeed had the great bulk of the party any thought beyond fettering the slave power for future aggression. On the other hand, to leave slavery untouched was not only to chill the energies of the most reliable upholders of the War, but to give foreign countries a pretext for asserting that the North was fighting merely for dominion, and that the Southern cause was that of liberty and morally entitled to help. The former horn of the dilemma was much the sharpest; and the government moved very cautiously, restraining its subordinates like Fremont (30 Aug. 1861) and Hunter (9 May 1862) from forcing its hand by emancipation orders. On 9 Aug. 1861 an act had declared masters employing slaves against the government barred from further claim to them; but that was a mere warning and rule of court. The first embarrassing problem was how to deal with slaves in conquered districts, or who had come within its lines: was the government to act as slaveholders' trustee and return them to servitude? The growing resentment against slavery as a convertible term for the rebellion, and disgust at being slave-catchers to the behoof of their enemies, supplied the answer, and on 13 March 1862 all army officers were forbidden to return fugitive slaves; their surrender from any quarter was made harder (though the fugitive-slave law was not formally abolished till 28 June 1864); on 17 June 1862 all captured, deserted, or fugitive slaves of owners in rebellion were freed. As to the main body, who plainly could not be left in unchanged status as the core of a fresh abscess, Lincoln's wish was for compensated emancipation; he sent a special message to Congress 6 March, and that body passed a joint resolution 10 April, declaring that the United States ought to co-operate with any State which would adopt gradual abolition, by paying for the slaves, and on 16 April those in the District of Columbia were thus emancipated; but despite his repeated urgencies, the border States would take no measures of the kind. On 19 June the slaves in the Territories were freed.

The final blow came, as John Quincy Adams 20 years before had forecast that it would, by using the President's war power to suppress insurrection. As the second year of the conflict wore on, the majority demanded the crippling of its enemy by the most efficient means, and very many believed that a threat of general emancipation would bring about a general surrender. Lincoln wished for a great victory first, that it might not appear the selfish resource of an overmatched power; but the discouraging Peninsular campaign obliged him to satisfy his supporters by holding this bludgeon over the enemy. On 22 Sept. 1862 he issued a proclamation announcing that 100 days after, on 1 Jan. 1863, the Executive would issue another proclamation designating the States or parts of States then deemed in rebellion, evidence to the contrary being the presence of *bona fide* representatives in Congress, that all slaves in the designated sections should be permanently free, and that the civil and military authorities of the United States would maintain their freedom, and would not repress any effort of theirs to make it good. The only result was a retaliatory proclamation by Jefferson Davis 23 December, ordering that captured negro Federal soldiers and their officers should be turned over to the States, and that Gen. B. F. Butler should be hanged if captured. On the 1st of January the threatened proclamation was issued, as "by virtue of the power in me vested as commander-in-chief of the army and navy of the United States, and as a fit and necessary war measure for repressing said rebellion." It designated Arkansas, Texas, Louisiana except 13 "parishes" or counties, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia except West Virginia and seven other counties, as in rebellion, emancipated all the slaves in them; enjoined these freedmen to abstain from all violence except in self-defense, and to work faithfully for reasonable wages; announced that suitable members of them would be received into United States military and naval service, and for this act invoked "the considerate judgment of mankind and the gracious favor of Almighty God."

The curious feature of this proclamation is that it abolished slavery only in the sections not under the military power of the United States, and left it untouched in those which were, namely, the ones specially excepted by it, "which are, for the present, left precisely as if this proclamation were not issued." Hence it was argued by the Democrats that it had no legal force whatever, and emancipated no one; a question the Supreme Court never passed on. It was always accepted by the majority party, however, as a continuing act, applying as fast as any of that territory fell into the Union power, and not necessary to repeat. Politically, the results were enormous. Recognition of the Confederacy thenceforward meaning a flat maintenance of slavery instead of freedom, the entire anti-slavery sentiment of France and Great Britain was thrown against those countries' interference, which at once be-

FROM THE PAINTING BY CARPENTER.

SIGNING THE EMANCIPATION PROCLAMATION.

came unthinkable. It drove away many lukewarm northern Republicans, and brought many local and State defeats to the administration; but it took the party "off the fence," and made it a coherent organization with one firm, open principle, for many years unassailable. In the South, as defeat meant emancipation by their enemies and it would be no worse if done by themselves, some of the leaders (as Lee) seriously thought of offering freedom to slaves to fight in their armies in the latter part of the War, hoping to save independence and the control of their own destinies at least.

Emants, ĕm'änts, **Marcellus,** Dutch poet and descriptive writer: b. Voorburg, near The Hague, 12 Aug. 1848. His volumes of travels display his keen observation and his poetical imagination. Among his best are: 'A Journey Through Sweden' (1877); 'Monaco' (1878); 'Along the Nile' (1884); 'From Spain' (1886). He holds a permanent place in the literature of the Low Countries through his charming narrative poems, 'Lilith' (1879); 'The Shimmer of the Gods' (1883).

Eman'uel the Great, king of Portugal: b. 31 May 1469; d. Lisbon 13 Dec. 1521. He ascended the throne in 1495. During his reign were performed the voyages of discovery of Vasco da Gama, of Cabral, of Americus Vespucius, and the heroic exploits of Albuqerque, by whose exertions a passage was found to the East Indies (for which the way was prepared by the discovery of the Cape of Good Hope in 1486 by Bartolomeo Dias), the Portuguese dominion in Goa was established, the Brazils, the Moluccas, etc., were discovered. The commerce of Portugal, under Emanuel, was more prosperous than at any former period. The treasures of America flowed into Lisbon, and the reign of Emanuel was justly called "the golden age of Portugal." He died deeply lamented by his subjects, but hated by the Moors and the Jews, whom he had expelled. As a monument of his discoveries, Emanuel built the monastery at Belem, where he was buried. He was a friend to the sciences, and to learned men. He left 'Memoirs on the Indies.'

Emba, ĕm'bä, a river in the district of Orenburg, Asiatic Russia; the Russians call it Jemba, the Kirghiz, Dchem. It rises at three sources in the western slope of the Mugodchar foothills; flows sluggishly through an area of steppes, is about 200 feet wide and 500 miles long, and forms a delta at its embouchure in the Caspian. It is not navigable, but abounds in fish. The fortress Embinsk is built on its upper waters.

Embalming, the act of preserving the body after death. It was probably invented by the Egyptians, whose bodies thus prepared for preservation are known as mummies, but it also prevailed among the Assyrians, Scythians and Persians. It is at least as old as 4000 B.C. The Egyptian mummies were placed in costly coffins ready for sepulture; but were frequently kept some time before being buried — often at home — and even produced at entertainments, to recall to the guests the transient lot of humanity. The usual method of embalming among the ancients was as follows: The intestines and brains were taken out, and the cavities filled up with a mixture of balsamic herbs, myrrh, etc.; the arteries and other vessels were injected with balsams The ancient Egyptians filled the cavities of the trunk with aromatic, saline, and bituminous stuff. The cloths in which the mummies were swathed were saturated with similar substances. So effectual were some of the processes that, after 2,000 or 3,000 years, the soles of the feet are still elastic and soft to the touch. By 700 A.D., when embalming practically ceased in Egypt, probably 730,000,000 bodies had been thus treated; many millions of them are still concealed. In 1881 upward of 30 mummies of potentates, including that of Rameses II., were discovered together at Deir-el-Bahari. (See MUMMY.) The Persians employed wax for embalming; the Assyrians, honey; the Jews aloes and spices. Alexander the Great was preserved in wax and honey. Desiccated bodies, preserved by atmospheric or other influence for centuries, have been found in France, Sicily, England, and America, especially in Central America and Peru. The art of embalming was probably never wholly lost in Europe. The body of Edward I., buried in Westminster Abbey in 1307, was found entire in 1770. The body of Canute, who died in 1036, was found very fresh in Winchester Cathedral in 1776. The bodies of William the Conqueror and of Matilda, his wife, were found entire at Caen in the 16th century.

Chaussier's discovery, in 1800, of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard and grayish, introduced new means of embalming; but, owing to the desiccation, the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Gannal, in 1834, and of arsenic by Tranchini, pyroxilic spirits by Babington and Rees in 1839, and of the antiseptic nature of chloride of zinc, have led to the application of these salts to the embalming of bodies required to be preserved for a limited time. The latest method common in the United States is an injection of a fluid into the femoral artery and the cavity of the abdomen. The most efficient agents are mercuric chloride, arsenic and zinc chloride.

ROGER S. TRACY, M. D.,
Health Department, New York City.

Embankment, a mound of earth, thrown up either for the purpose of forming a roadway at a level different from that of the natural surface of the ground, or for keeping a large body of water within certain limits. The slopes should be adapted to the material, so as to secure permanence. To prevent subsidence on marshy or peaty soils, either the weight of the heart of the embankment is diminished, as in Holland, by introducing layers of reeds, or fascines, or artificial foundations are prepared. The embankment may be prevented from slipping laterally by forming steps in the earth of the subsoil, or by cutting deep trenches at the feet of the slopes. In cases where embankments are raised for the storage of water, a "puddle-dike," that is, a water-tight wall, must be inserted through the whole depth of the bank down to the impermeable strata beneath. To resist the action of wind and rain, or of the waters of a slow-flowing stream, the banks should in all possible cases be covered with turf. When embankments are raised at right angles to the current of a river they are called dams.

When they run parallel to the current, and prevent its lateral overflow they are styled levees. Among the largest embankments hitherto executed are those on the banks of the Po, the Meuse, the Scheldt, the Mississippi, United States, on the shores of the Netherlands, and the Croton dam at the head of the reservoir for the supply of water to New York, the Oberhäuser embankment on the Augsburg & Lindau Railway, the Gadelbach cutting on the Ulm & Augsburg Line, and the Tring cutting on the Northwestern Railway (England). See LEVEES; RESERVOIRS.

Embargo in the United States. Prohibition of foreign commerce, to distress foreign countries and obtain the revocation of hostile measures; «peaceful war,» intended to be cheaper than actual warfare and equally efficient, but in fact injuring ourselves deeply and the others little, and ending in real war at last. Our embargos belong exclusively to the French-English wars of 1794–1814. Their ultimate cause was that the agricultural classes, who controlled the administration, did not believe in commerce, and preferred abolishing it to spending anything for its protection; moreover, they were mainly southern and democratic, the commercial interests mainly New England and Federalist, and the former were not loth to spare themselves the cost of war by impoverishing the latter. The first embargo was for 60 days, due to mutual orders of France and England for seizure of neutrals which placed the United States between hammer and anvil. Jay's Treaty (q.v.) of 19 Nov. 1794, for 12 years measurably protected our commerce, but near its end conditions became infinitely worse. In 1806–7 the thronging mutual blows of England and Napoleon, ending in the former's Orders in Council of 11 November, and the latter's Milan Decree of 7 Dec. 1807, made practically every neutral vessel good prize to one or the other. Even more intolerable were the rights of search and impressment claimed by Great Britain, which swept several hundred American sailors every year into the British fleets, and in one massacre (see CHESAPEAKE AND LEOPARD) outraged and humiliated this country beyond forgiveness. But aside from the reasons above given, few landsmen believed till the victory of Old Ironsides (see CONSTITUTION, THE) that American ships could fight English on equal terms, and it was the general conviction that in case of war our entire fleet would at once be «Copenhagenized» (that is, captured bodily and added to the British fleet, as was the Danish). At Jefferson's recommendation, therefore, «The Embargo» was passed 22 Dec. 1807, forbidding all foreign commerce till the obnoxious decrees were repealed. The havoc not only in trade but in the interior life of the people was terrific; the exports fell from $110,084,207 in 1807 to $22,430,960 in 1808. The farming sections were dismayed to find that commerce meant part of their daily bread as well as the carriers' profits, and that they raised and sold much of that $87,000,000; but they clung all the more stubbornly to their anti-war recipe, though England and France approved it highly. Napoleon was glad to see his enemy drifting into war with a western power: England was glad to regain her carrying trade, and see Canada and Nova Scotia receive American capital. Meantime New England fought it with the fierceness of a struggle for life; evaded it largely by sea, and sent armies of smugglers overland to Canada. Congress then extended the act to rivers, lakes, and bays, and allowed collectors to seize on suspicion; and the next Congress, 9 Jan. 1809, passed a savage enforcing act with all the fury of baffled doctrinaires, imposing enormous fines, forfeitures, and bonds, and making the collectors supreme despots of their districts. New England was nearly in insurrection; the collectors were in danger of the fate of those under the Stamp Act, some resigned, others were sued in the State courts; the judges would give no findings against smugglers; finally the States threatened nullification, and John Quincy Adams (a victim to its support) declared that they had resolved to withdraw from the Union, at least temporarily, if force were used, and had opened negotiations with Great Britain. A Federalist declared in the Senate that blood would flow. The Democrats were frightened, and hastily fixed (3 Feb. 1809) 4 March for its discontinuance. But the next month they had regained courage, and passed a «non-intercourse act» to take its place; still prohibiting intercourse with France or Great Britain, but restoring it with other countries and allowing free coasting trade. This policy was continued till the War of 1812 opened. The hostility of New England to the war, only less destructive than the embargo and against her political feelings, induced the British government ostentatiously to relieve that section from the blockade, to sow discord and make a base of naval supplies; and on 17 Dec. 1813 a new embargo was laid to 1 Jan. 1815, which, however, was repealed 14 April 1814. Jefferson always asserted that the policy was the best, and the embargo would have accomplished its object if New England would only have helped. (Histories of the United States through this period, as Schouler, McMaster, etc.; especially Henry Adams' 'History,' covering 1801–15, devoted to the causes and consequences of these measures.

Em'bassy (*ambassy*, from O. Fr. *ambassée*, from low Lat. *ambachus*, a servant, vassal) in its strict sense, signifies a mission presided over by an ambassador, that is, a diplomatic agent of the first rank, as distinguished from a legation or mission entrusted to an envoy or agent. The difference between the powers and privileges of an ambassador and an envoy is, that the former, as the representative of the person of his sovereign, can demand a private audience of the sovereign to whom he is accredited, while the latter must communicate with the minister for foreign affairs. See DIPLOMACY.

Ember-days, called in the Roman Missal and Breviary *Quattuor Tempora* (the four seasons) and in the Anglican 'Book of Common Prayer' «Ember-days at the four seasons,» are in the Roman and in the Anglican calendar the Wednesdays, Fridays, and Saturdays which come next after 13 December, the first Sunday of Lent, the Feast of Pentecost (Whitsunday), and 14 September, respectively. In both the Latin Church and the Anglican these days are days of fasting. The *Quattuor Tempora* were observed at Rome in the time of St. Augustine (the bishop of Hippo, early in the 5th century), and doubtless the observance was already of ancient date. The custom was brought into Britain by that other St. Augustine who was the herald of the gospel to the Anglo-Saxons. It was anciently the custom for bishops to hold ordinations only on the Saturdays of the *Quattuor Tempora*. The origin of the phrase Ember-days cannot be definitely ascertained: but it is probably a corruption of *Quattuor Tempora,* as in German *Die Quatember* signifies the Ember-weeks.

Ember, or **Immer Goose,** the name in northern Scotland of the loon. See DIVER.

Embezzlement (O. Fr. *besiler,* to rifle, lay waste) is the appropriation, by a clerk or servant, of money or property put into his hands for trust. Embezzlement is both a theft and a breach of trust; yet, by the general law, it is only a ground for an action for the value of the property. It must not be confounded with larceny, which is "the felonious taking and carrying away the personal property of another." This "taking" implies a trespass, not to be chargeable in embezzlement, which is an offense or form of crime invented by the English statute, which the United States copied and which changed what was not larcenous into a punishable crime, being the act of fraudulently appropriating to personal use money or property held under a fiduciary relation. This crime in the United States is very severely punished as a felony.

Em'blements (O. Fr. *emblaement,* from *emblaer,* to sow with grain), a term applied to the growing crops of land when the lease of a tenant for life has expired by the death of the tenant, or when an estate at will has been determined by the lessor. In either case the emblements belong to the tenant or his executors. But when the tenant puts an end to his occupation by his own voluntary act, he will not be entitled to the crops.

Embolism, ĕm'bō-lĭzm (Gr. εμβολισμος, intercalation, 'εν, in, and βάλλειν, to cast). In the calendar, an intercalation of a day, as in the second month of our year in leap-year, or of a lunar month, 28 days, in the Greek calendar. In medicine, the blocking up of a blood-vessel by a clot of blood that comes from some distance till it reaches a vessel too small to permit its onward progress. This is often the cause of sudden paralysis and death, or of gangrene and pyæmia.

Embos'sing (Fr. *bosse,* a protuberance), the art of producing raised figures upon plane surfaces, such as on leather for bookbinding, etc.; on paper, wood, or bronze. In architecture or sculpture, in proportion as the figures are more or less prominent, they are said to be in *alto, mezzo,* or *basso relievo* (high, half, or low relief). Leather, paper, and textile fabrics are embossed by powerful presses furnished with dies of the desired pattern.

Embra'cery (O. Fr. *embraser,* to set on fire), an attempt to corrupt or influence a jury by money, promises, letters, threats, or persuasions. This offense in the United States is punished by fine and imprisonment.

Embrasure, ĕm-brā'zūr, in fortification, an opening made in the breastwork or parapet of a battery or fortress, to admit of a gun being fired through it. See FORTIFICATION.

Embree, Charles Fleming, American author: b. Princeton, Ind., 1 Oct. 1874. He is the author of ‹For Love of Tonita› (1897); and ‹A Dream of a Throne› (1900); ‹Heart of Flame.›

Embro, a corrupted form of the name Edinburgh. See EDINBURGH.

Embroidery, the art of producing ornamental patterns by means of needlework on textile fabrics, leather, and other materials. It is closely allied to tapestry, from which, however, it must be distinguished. The essential distinction is that in tapestry work the basis is a series of parallel strings, forming a warp, and the patterns are produced by the manipulation of the threads which form the weft, while embroidery is always worked on an already complete fabric.

The art of embroidery is practised, with characteristic variations, by the rudest tribes, and was well known in very early times. Remains of Egyptian embroidery as ancient as the days of Jacob exist still; and the costumes painted on the monuments of the 18th dynasty show that the most varied patterns were used by the Egyptions 3,000 years ago. The Jews probably acquired the art in Egypt; the description of the curtains of the tabernacle and the garments of Aaron (Exodus xxvi., 1-31, and xxxix.) and other allusions in the Scriptures indicate that their skill in the art was considerable. The knowledge of artistic embroidery came to Europe from the East, where it had its early home, and where it is still most largely practised. To the Greeks and Romans it came from Phrygia, whence at Rome the embroiderer was known as *phrygio,* and embroidered work was called *phrygium.* Frequent references to embroidery are found in Homer, and all later classical writers. It was in mediæval times that the embroiderer's art attained its greatest perfection in Europe, and embroidery was a favorite occupation of women of all ranks. Not only was figure and portrait embroidery highly developed, but, in France especially, much attention was paid to the use of floral and arabesque ornament. Much of the most beautiful mediæval work is found on the vestments and ornaments for the monasteries and churches. Among other famous specimens are two of English origin, the Syon cope of the 13th century, richly charged with scriptural subjects, and the Bayeux Tapestry (q.v.), an example of embroidery with worsteds.

At the present day the Orient stands foremost in art embroidery. The Chinese work is perhaps the most elaborate, done mostly on silk, with brilliant colors; the Japanese embroidery is scarcely less beautiful and elaborate. In Europe and America, there has been in the 19th century a revival of the art of embroidery connected with the increased desire for all forms of decorative art. Practically, embroidery is divided into two distinct classes of work: (1) that which embraces all kinds of artistic needlework done by the hand; and (2) the manufacturing industry which includes all embroidery done by machinery, and hand needlework done on the large scale by following patterns mechanically impressed on the fabric. In art embroidery the materials employed are fine colored worsted yarns called crewels, tapestry wools, embroidery silks, gold and silver threads, spangles, and plates or disks of metal. The textile basis may be any cloth, but the fabrics principally used are stout makes of linen, silks, satins, velvets, and flannels. Small work is done without any special mounting, but for elaborate designs the fabric is fitted and tightly stretched on a frame. The number of embroidery stitches is considerable, and they vary with the nature of the design and the materials used. The principal stitches are the cross stitch, the cushion stitch, the crewel stitch, the outline stitch, the herring-bone stitch, the button-hole stitch, the feather stitch, the satin stitch (the best for fine work on silk and satin), and the rope and knot stitches. In frame-work, "couching" is largely employed, which consists in laying lengths of thread on the surface, and securing them by stitches through the cloth brought up at various points. A distinct class of embroidery consists of appliqué or cut work, in which designs of different materials and colors are cut out and sewed down on the surface of the fabric to be ornamented. In its purely mechanical side, the embroidery trade embraces several distinct sections, of which may be enumerated: (1) white embroidery, known also as Swiss or Scotch sewed work; (2) embroidery in gold, silver, and colored silks, for official costumes, civil and military, badges, etc.; and (3) embroidery in crewels, or other colored wools, colored silks, etc., mostly done for furniture decoration, such as borders of table covers. To a great extent these various kinds of embroidery can be worked by one or other of the machines which have been devised for embroidering. The first successful embroidery machine was that invented by M. Josué Heilmann, of Mülhausen, patented in England in 1829. With Heilmann's machine, or the modifications of it which have since been introduced, one person can guide from 80 to 140 needles working simultaneously, and producing so many repeats of the same design. Embroidery patterns, in a variety of knotted, tambour, and other stitches, and ornamental braiding, are now very largely done by means of the Bonnaz machine, the invention of M. Antoine Bonnaz, first patented in England in 1868.

Bibliography.— Day and Buckle, 'Art in Needlework' (1900); Higgin, 'Handbook of Embroidery'; Lefébre, 'Embroidery and Lace' (Eng. trans. 1888); Morris, 'Decorative Needlework'; Palliser (Mrs. Bury), 'Lace and Embroidery.'

Embrun, ŏṅ-brŭṅ (ancient *Eburodunum Caturigum*), France; town in the department of Hautes-Alpes, on a rocky eminence in the centre of a large plain watered by the Durance, 20 miles east from Gap. It is an ancient place, surrounded by walls and ditches, and of very picturesque appearance. It was pillaged successively by Vandals, Huns, and Saxons, and its inhabitants almost exterminated by the Moors in 966. It is still a bishop's, and was once an archbishop's, see. Pop. 3,812.

Em'bryo. See EMBRYOLOGY.

Embryology (ἔμβρυον, a young animal + λόγος, discourse), strictly speaking, is that division of biological science which deals with the structure and growth of the embryo, that is, the young before it is capable of leaving the egg membranes and leading an independent existence. But such limits are inconvenient and the term as usually employed treats of the larval history as well, including all phases of growth until practically the adult form, if not size, is reached.

The account of embryology begins with the egg or *ovum*. This is a specialized cell (see CELL) formed in the reproductive glands (ovaries) of the mother and differs from all other cells of the body in its capacity, under the proper conditions, of reproducing an animal like the parent. The eggs of different animals vary greatly in size and appearance. In the simplest condition, as in the starfish and sea-urchin, the egg is a spherical mass of protoplasm (q.v.), with a central specialized portion, the nucleus, all being transparent and having a diameter of about one two hundredths of an inch. From this all variations in size and structure can be traced to the complicated and comparatively enormous eggs of birds. These variations are due to secondary features which are added for the protection and nourishment of the growing embryo.

Thus in the familiar hen's egg there is an external calcareous shell, then the double shell membrane enclosing the albumen or "white." Supported in the white is the yolk, which alone arises in the ovary, the other parts being added by the ducts through which the egg passes on its way to the exterior. Hence the yolk alone is the true egg. This owes its large size (compared with the egg of the starfish) to the fact that it contains not only the protoplasm and nucleus of the latter, but also a large amount of food material (food yolk or deutoplasm). On one side of the yolk is a lighter yellow spot (the "tread"), and in this spot are the nucleus and protoplasm, and in it the processes of development begin. All other parts are secondary or adventitious, and it is to the number, character and amount of these that the differences between the eggs of various animals are due.

In the limits of this article only the simplest and most essential features of development can be described; for details the reader must go to special works, but with greater or less modifications the following account will apply to all eggs.

The egg, as it leaves the ovary, is not ready for development. It must become mature. This process of *maturation* is very complex. In a few words it consists of the formation of two small bodies (*polar globules*), which are thrust out of the egg and play no part in its further history. These polar globules carry with them a small amount of protoplasm and three quarters of the essential material (*chromatin*) of the nucleus. This division of the chromatin is peculiar in that with the formation of the first polar globules half of each kind of chromatin is cast off; with the formation of the second half of the kinds of chromatin are lost. In the formation of the male reproductive element, the *spermatozoon*, there is an essentially similar division of the chromatin. Upon these divisions of the chromatin and the subsequent fertilization of the egg next to be described, all modern theories of heredity are based. After the polar globules are formed the remainder of the original nucleus sink back into the egg and form a *female pronucleus*.

After maturation comes fertilization, which consists in the union of a spermatozoon with the egg. The head of the male element penetrates the protoplasm, increases in size, and forms a *male pronucleus*. The two pronuclei unite and thus there is restored to the egg those chromatin elements which were lost in the formation of the second polar globule. It is to be noticed that in eggs which develop parthenogenetically (that is, without fertilization — see PARTHENOGENESIS) the second polar globule is not formed and hence no lost chromatin has to be restored.

Excepting parthenogenetic eggs it is only after fertilization that the egg is normally ready to develop and to begin the formation of the embryo. The first step is the division of the single-celled egg into numerous cells, the so-called *segmentation of the egg.* In the simplest eggs these divisions are regular and total, that is, at each division the resulting cells are equal in size and the planes which separate them cut entirely through the egg. With increase in amount of deutoplasm, as in the egg of the frog, there is a difference in the size of the cells, those at one pole being large, those at the other small (*unequal segmentation*). With still further increase in the amount of food yolk, only a part of the egg divides, and we have *partial* or *meroblastic segmentation,* as in the case of sharks, reptiles, and birds. These variations exercise a great influence upon the subsequent history of development, modifying the various processes in ways which are described in embryological text-books. The peculiar *centrolecithal* eggs of crustacea and insects need not be considered here.

In eggs with equal and total segmentation the first division plane cuts the egg into equal halves. The second plane, at right angles to the first, results in quarters. These two planes, from their relation to the meridians of the globe, are termed meridional planes. The third, which is at right angles to the first two, corresponds to the equator and divides the four cells into eight. After this meridional planes and planes parallel to the equator alternate, increasing the cells in geometrical ratio so that we have 2, 4, 8, 16, 32, 64, 128, 256, etc., cells as a result. In unequal segmentation this regularity is soon lost, while in meroblastic eggs the divisions result in a small patch of cells, the *blastoderm,* on one side of the yolk, as in the hen's egg at the time of laying.

At first the cells resulting from this segmentation form a solid mass known as the *morula* (mulberry) stage. Later this becomes a hollow sphere of cells, one layer thick, the so-called *blastula* (Fig. 1 left), its cavity, in contradistinction to other cavities which may appear later in the embryo, being known as the *segmentation cavity* or *blastocœle* (archicœle). In eggs with regular segmentation the wall of the segmentation cavity is composed of equal-sized cells,

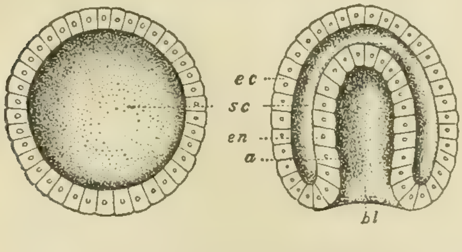


FIG. 1.— Diagrammatic sections of blastula (left) and gastrula (right); *a,* archenteron; *bl,* blastopore; *ec,* ectoderm; *en,* entoderm; *sc,* segmentation cavity.

but in unequally segmenting eggs the cells on one side are thicker than those on the other and the segmentation cavity is more or less excentric in position.

Next in sequence is the differentiation of the single layer of cells of the blastula into the two primary *germ layers.* The process may be compared to forcing in one side of a hollow rubber ball. One side of the blastula becomes turned into the other, partially or completely obliterating the segmentation cavity. In this way two layers are formed, an outer *ectoderm* (*epiblast* of English embryologists) and an inner *entoderm* (*hypoblast*). The opening into the cavity of the entoderm is known as the *blastopore,* while the cavity itself, from the fact that it forms the digestive tract of the adult, is called the *archenteron,* while for similar reasons the embryo at this stage is termed the *gastrula* (Fig. 1 right). In eggs with unequal segmentation it is the larger cells which form the entoderm, and in this way the food yolk, to which they owe their size, is brought into the walls of the digestive tract. In eggs with meroblastic segmentation the phenomena of formation of the gastrula are greatly modified and are impossible of description in a few words. They can, however, be harmonized with the foregoing account.

The mouth of the gastrula (blastopore) may remain permanently open and form the mouth of the adult, or it may close in the middle, the ends remaining open as mouth and anus. Again only one end may remain open, this forming in some the mouth, in others the anus. Lastly the blastopore may close completely and either mouth or anus may be formed outside its line of closure. From this it is evident that it is important to recognize the limits of the blastopore in tracing resemblances between different groups of animals, and this necessity is increased when we recollect that the central nervous system arises around the blastopore.

In some Cœlenterates and scattered members of other groups of animals the two layers, ectoderm and entoderm, may arise in a different way. On arrival at the stage of the blastula the inner ends of the cells which compose its walls become cut off from the outer ends, thus forming the two layers. While in this case the segmentation cavity becomes converted into the archenteron. This process is called *delamination* and is difficult to reconcile with the process described above.

In many Cœlenterates and a few other imperfectly known forms, the adult animal does not progress beyond the two-layered stage and hence these are sometimes grouped as the *Diploblastica,* in contrast to the *Triploblastica,* in which a third layer is added. This additional germ layer is the *mesoderm* (mesoblast of the English). It arises either from the entoderm or from the line of junction between ectoderm and entoderm and extends into the space (remains of the segmentation cavity) between these two layers, making up, in most animals, by far the largest part of the adult body. It shows considerable differences in its method of origin even in one and the same animal, and is frequently subdivided by writers into *mesothelium* and *mesenchyme* by characters which need not be detailed here.

From these three (or four) germ layers all the structures of higher animals (metazoa) arise. The derivation of the various structures in man may be enumerated here.

Ectoderm.— External layer (epidermis) of skin, hair, nails, sweat and milk glands, brain, spinal cord, nerves, the sensory portions of ears, eyes, nose, etc., lining of mouth, enamel of teeth.

Entoderm.— Lining of digestive tract (including its glands — liver, pancreas, etc.) of Eustachian tube, windpipe, lungs and lining of lungs not of notochord.

Mesothelium.— Lining of body cavity (peritoneum), pleura, and pericardium; all voluntary muscles of the body and muscles of the heart; internal reproductive and excretory organs.

Mesenchyme.— Deeper layers (derma) of skin, and of alimentary tract; tendons, fat, cartilage, bone, dentine of teeth; involuntary muscles with the exception of those of the heart; blood-vessels, blood, and lymph.

Space will not permit tracing the development of the various organs of all animals from

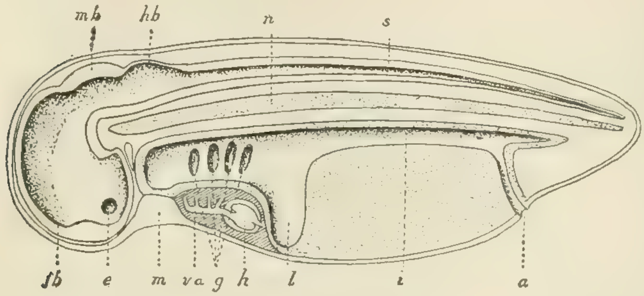

FIG. 2.— Diagrammatic long section of a salamander embryo. *a*, anus; *e*, place of outgrowth of eye; *fb*, fore-brain; *g*, gill slits extending outward from pharynx; *h*, heart in pericardium; *hb*, hind-brain; *i*, intestine; *l*, beginning of liver; *m*, thickening of ectoderm where mouth will form; *mb*, mid-brain; *n*, notochord; *s*, spinal cord; *va*, ventral aorta. Cut surface of entoderm dotted.

these germ layers, but later in this article a slight sketch of the processes as they occur in the vertebrates will be given.

From the stage in which the germ layers are formed some animals develop directly into the adult, while in others larval stages, differing markedly from the adults in appearance, are introduced. In some instances these larvæ are clearly adaptations to enable the young to begin its free life and its self-support as early as possible; in others they are indicative of the ancestry, representing, in the history of the individual, stages passed through in the development of the race. Larvæ are more abundant among marine than among fresh-water or terrestrial forms. See LARVA.

Development of Organs.— Space will permit the outlining of the development of organs from the germ layers in but one animal. For reasons of simplicity and of general interest the salamander has been selected as a type of the group of which man is a member.

The eggs of the salamander are laid in the spring, enclosed in a transparent jelly. They are fertilized after being laid, form polar globules, and undergo a total but unequal segmentation, a result of the large amount of food yolk present. The small segmentation cavity is consequently excentric in position. Since the segmentation cavity is small the gastrula cannot be formed in the typical way described above, but rather by a modified type of infolding, not easily described in a few words. The blastopore closes along what will eventually make the middle line of the back, the egg changing during this process from a spherical to a more elongate form.

On the dorsal surface, around the line of closure of the blastopore, the ectoderm becomes thickened, forming a *medullary plate*, broader in front. The edges of this plate gradually rise, roll inward toward each other and gradually convert the plate into a tube, from which later will develop the central nervous system. The broader anterior portion gives rise to the brain (Fig. 2), the rest to the spinal cord, while the lumen of the tube forms the canal of the cord as well as the cavities (ventricles) of the brain. Starting from this central system the nerves attain their outward growth later.

The eyes arise in large part from the brain, extending outward from it as hollow vesicles which grow laterally toward the ectoderm of the side of the head. Then the vesicle becomes folded into itself like a double cup, the inner wall of which gradually develops into the retina, while the optic nerve grows backward along the line of the stalk of the cup into the brain. The lens of the eye has its origin in the ectoderm of the side of the head opposite the outgrowing optic vesicle. This thickening increases, becomes folded into a ball and becomes cut off from the rest to sink to its permanent position at the mouth of the optic cup. The essential or sensory part of the ear begins as a pit on the side of head behind the eye. This deepens and sinks inward to join the outgrowing auditory nerve. It later becomes closed and completely cut off from the skin and by a complicated process of folding becomes developed into the two chambers and the three semicircular canals of the adult, these corresponding in position and origin to those of man. (There are no middle and outer ears in the salamander.)

The entoderm, arising by the modified process of gastrulation, becomes more and more elongate with the lengthening of the embryo. Behind, the canal (archenteron) remains small (Fig. 2, *i*), the ventral wall being enormously thickened by the large amount of yolk present. In front the cavity enlarges to form the liver (*l*), while in front of this is a short portion which has to develop into pharynx, gullet, and stomach. As yet there is no mouth. This arises first as an inpushing of the ectoderm in front (*m*) which later breaks through into the pharynx. In the pharyngeal region paired pockets grow out right and left until they meet the ectoderm with which they fuse (*g*). Then at the bottom of each pocket an opening appears so that this region is in connection with the exterior. These openings are the gill slits. Similar gill pouches are formed in the embryos of all vertebrates, but in the higher groups (reptiles, birds, and mammals) they are transitory with the exception of the anterior which forms the middle ear (tympanum) and Eustachian tube of the adult. Œsophagus and stomach develop later by elongation and differentiation of the region between the liver and pharynx, while the intestine arises from the part behind the liver outgrowth.

The mesoderm grows in as two double sheets between the ectoderm and entoderm (Fig. 3, *m*), the space between the two layers being called the cœlom (*c*). These mesodermal sheets extend on either side of the body from near the tip of the head to the end of the tail. At first they are dorsal in position, but with increase in size the lower margins approach the mid-ventral line, where they finally fuse.

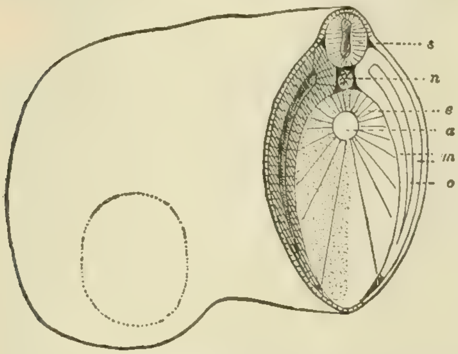

Fig. 3.—Diagram of anterior part of amphibian embryo; *a*, alimentary canal; *c*, cœlom or body cavity; *e*, entoderm; *m*, two layers of mesoderm; *n*, notochord; *s*, spinal cord.

The dorsal portion of each mesoderm plate soon becomes cut up into a series of cubical blocks, the *myotomes*, each myotome containing a portion of the cœlom. These myotomes are to furnish the voluntary muscles of the body. They finally separate completely from the rest of the mesoderm and begin to grow downward between the ectoderm and the lower part of the mesoderm until they extend to near the middle ventral line. During this process the inner wall of each myotome becomes transformed into muscle fibres and in this way plates of muscle (familiar to all in the flesh of a fish) arise. The muscles of the limbs arise as buds from a few myotomes in the regions where the limbs are to appear. With the outgrowth of the limb the buds extend into it and gradually become differentiated into the various muscles. The outer layer of the myotome is not transformed into muscle but gives rise to a connective tissue, the *cutis* or *derma*, which, together with the ectoderm (*epidermis*), forms the skin.

From the region just below the myotomes a second series of segments are formed which have for their most marked functions the formation of the excretory organs, and hence are called nephrotomes (ἐφρόδυ, kidney). The history of these organs is too complex to be followed here. Suffice it to say that in the salamander as in all fish-like vertebrates (Ichthyopsida), there are two kidneys formed in succession, an anterior head-kidney (*pronephros*) and a posterior Wolffian body (*mesonephros*), the latter forming the functional kidney of the adult. In the higher vertebrates (reptiles, birds, and mammals) both pro- and mesonephros are formed in the embryo and these are replaced later by a third kidney (*metanephros*) which alone serves an excretory organ in the adult. The nephrotomes also give rise, directly or indirectly, to the ducts of the reproductive and excretory organs, while from the inner surfaces are budded off cells (mesenchyme) which, among other functions, have to form the skeleton, mentioned below.

The lower portion of the mesoderm does not become divided as do the two upper regions. Its outer wall becomes applied to the muscles, while its inner covers the various viscera, thus forming the lining or *peritoneum* of the lower part of the cœlom which is usually called the body cavity. The only division of this cavity in the lower vertebrates is by means of a transverse partition, the *septum transversum*, which separates an anterior *pericardium* containing the heart from the peritoneal cavity containing the other viscera. In the mammals a second partition, the *diaphragm*, occurs behind the first, marking off the pleural cavities, containing the lungs, from the rest of the peritoneal cavity.

The first skeletal structure to appear is the notochord, a rod of gelatinous tissue which arises in the middle dorsal line from the entoderm, becomes cut off from it and comes to lie between the digestive tract and the central nervous system (Figs. 2, 3 *n*). Behind, it extends to the tip of the tail, but in front it does not reach the tip of the head, but is terminated at a down-growth from the brain, the infundibulum. This rod is not jointed, but serves as a centre around which the vertebræ and the base of the posterior part of the skull arise.

The tissue for the vertebræ and the floor of the skull is furnished by the mesenchyme from the nephrotomes, the origin of which was alluded to above. This tissue gathers around the notochord and forms rings around it, the bodies of the vertebræ; while connected with each body is a plate on either side, the two plates meeting above the spinal cord and forming the *neural arch*. Extending outward between the muscle plates are the rudiments of the ribs. At first vertebræ and ribs are cartilaginous, but later the cartilage becomes replaced by bone. In the head region a cartilaginous skull arises in a somewhat similar way. This is very complex, but may be divided into a cranial and a visceral portion, the latter consisting of cartilage bars for the jaws and between the gill slits. In the cranium only that part which arises around the anterior extremity of the notochord can be compared to the vertebræ. This cartilaginous skull becomes converted into the bony skull of the adult, in part by direct conversion of the cartilages into bone, in part by the formation of additional bones (dermal bones) in the skin which unite with those of cartilaginous origin. The skeletons of the girdles and limbs are almost entirely of cartilage origin, only the coracoid arising as a dermal bone.

The circulatory system is very complicated and only a small part of its development can be outlined here. In the pharyngeal region the descending plates of mesoderm meet below the entoderm, enclosing between them a tube lined by cells of uncertain, though probably of entodermal origin. These cells form the lining of the heart (*endothelium*), while the walls of mesoderm later furnish the muscles of this organ. The cœlom of this region becomes converted into the pericardial cavity.

At first this heart tube is straight, but since it grows faster than the pericardium it becomes twisted somewhat like the letter S and the auricle and ventricle develop out of the folds of the twist (Fig. 2, *h*), valves soon appearing between these chambers. Behind the heart the edges of the mesoderm are prevented from joining by the presence of the liver and hence there arise here two vessels which bring the blood from behind to the heart. In front of the heart is formed in a similar way a tube, the ventral aorta (Fig. 2 *va*), from which vessels (*aortic arches*) gradually grow upward around the pharynx in the tissue between the gill slits. These finally enter vessels above the pharynx which by their union form the dorsal aorta which runs backward above the alimentary tract to the tail. From this dorsal aorta vessels are given off at regular intervals which extend out laterally between the myotomes and serve to carry blood to these last.

From this comparatively simple arrangement the more complicated blood system of the adult is developed by the appearance of other vessels and the disappearance of some which are formed at first; the details of which must be sought in special works. One or two points have more interest and may be mentioned here. For various reasons it seems certain that in the early vertebrates there were formed six pairs of these aortic arches connecting the ventral and dorsal aortæ. In the salamander only the posterior four of these come to development, the anterior two on either side remaining rudimentary. In the development of the higher animals, as in man, there is the same formation of paired arches in the early embryo. Later in the history the fifth arch on either side is entirely lost, the sixth loses its connection with the dorsal aorta and sends its blood to the lungs, thus giving rise to the pulmonary arteries. Of the third pair that on the right side largely disappears, while that on the right persists as the "arch of the aorta" of human anatomy and alone carries blood to the dorsal aorta and the trunk. The anterior arches also lose their connection with the posterior dorsal trunks and give rise to the carotid arteries which carry blood to the head.

With this outline of the comparatively simple development of the salamander the more complicated features of the history of a higher vertebrate can better be understood. In many of their features these closely parallel the account just given. In the reptiles, birds, and mammals other features are added. Thus at an early stage there is formed an embryonic envelope which encloses the whole germ. In some mammals as in man this arises by a splitting of the ectoderm so that the embryo comes to lie in a cavity roofed in above by a delicate membrane, the *amnion*. In many other mammals, as in reptiles and birds, this amnion arises by an up-growth of ectoderm all around the embryo, these growths finally meeting and fusing above the embryo, thus finally enclosing an amniotic cavity similar to that in man.

In the salamander egg, the amount of food yolk is comparatively small. In the birds and reptiles it is enormous in amount. As a result the young reptile or bird appears as a small outgrowth on the surface of a large sphere of yolk. The presence of this causes the blood vessels described above as entering the heart from behind to extend down over the yolk, while other vessels extend to the same region from the dorsal aorta. By means of these a yolk circulation is set up and thus the yolk itself is gradually torn down and carried by the vessels into the circulation and thus used in building up the body. Later this yolk circulation, lying beneath the egg shell, serves as a means of respiration, absorbing oxygen from the air and giving off the carbon dioxide produced by growth.

In most mammals the whole embryonic period (including the fœtal stages) is passed inside the mother, a fact which has resulted in considerable modifications of the processes. Thus the egg has lost its food yolk and has a total, although irregular, segmentation. Larval organs have been lost, but the most remarkable changes are the provisions for furnishing nourishment to the growing embryo and the later fœtus. These may be briefly summarized by saying that an outgrowth occurs at the hinder end of the alimentary canal, the *allantois*, which carries with it arteries and a vein. This allantois increases in size, extending outward into the amniotic cavity, and finally uniting with its outer wall, the chorion. From this union is developed that structure so characteristic of mammals, the *placenta*. This portion comes in contact with the walls of the maternal uterus, while from its outer surface are developed numerous small, thread-like outgrowths, the chorionic villi. These penetrate into the uterine walls, which in the meantime have become spongy through the great development of blood vessels, and from this union the placenta is formed. Blood (or rather its serum) passes by osmosis from the vessels of the uterus into the villi and thence by the allantoic vein to the embryo, while blood which has done its work in the embryo is carried back by the same course to the mother. It is to be noted that at no time is there a direct connection of the blood vessels of parent and off-spring, all transfer being osmotic.

With growth the placenta increases in size, while the stalk of the allantois and accessory structures remain small, and these smaller portions form the umbilical cord. The placenta varies in different animals, three chief types being recognized. In the cotyledonary, as in domestic cattle, the villi are gathered in numerous small patches or cotyledons; in the zonary type, as in dogs, the villi form a girdle or zone around the fœtal envelopes; while in the discoidal condition (man), the villi occupy a disk-like area on the envelopes. At birth the young mammal is in position to breathe for itself and to take food into the alimentary canal and hence the placentar structures are no longer of value. They are, therefore, cast out as the "afterbirth," carrying with them a part of the uterine lining.

The literature of embryology is very large and reference can be made to but a few manuals, which, however, have good bibliographies. A classic work is Balfour's 'Treatise on Embryology' (2 vols., London 1880–1), which includes all groups of animals. Most recent for invertebrates is the Embryology of Korschelt and Heider (translated in 4 volumes, 1900). For vertebrates the best text-books are Minot, 'Human Embryology' (1892), and Mark's translation of Hertwig's 'Embryology' (1892). A smaller, more recent and very clear work is McMurrich, 'Development of the Human Body' (1902). All of these, while emphasizing man in the titles, deal with other vertebrates.

J. S. Kingsley,
Professor of Zoology, Tuft's College.

Embury, Emma Catharine Manley, American writer: b. New York 1806; d. Brooklyn, N. Y., 10 Feb. 1863. She was married to Daniel Embury in 1828. Much of her work for periodicals was over the pen-name "Ianthe." Among her published works are: 'Guido and Other Poems' (1828); 'Female Education'; 'The Blind Girl, and Tales'; 'Love's Token Flowers' (1846); 'Poems' (1869).

Embury, Philip, Methodist clergyman: b. Ballygaran, Ireland, 21 Sept. 1729; d. Camden, N. Y., August 1775. He joined John Wesley's society and became a local preacher at Court-Mattress in 1758. Emigrating to New York in 1760, he began to preach in his own house in 1766, and two years later erected a chapel on the site of the present "Old John Street Church." Being a carpenter by trade, he worked on the building with his own hands and completed the pulpit, in which he preached the sermon of dedication 30 Oct. 1768. This was the first Methodist chapel of the New World, and he has been called "the founder of American Methodism." It was, however, at Camden, Washington County, N. Y., that he did his greatest work, forming there a congregation which grew into the flourishing and influential Troy Conference.

Em'den, Germany, town, in the province of Hanover, on the Ems, near where it discharges itself into the Dollart estuary. Emden has an excellent roadstead, and its harbor is connected with this by a canal admitting large vessels. The Dortmund-Ems and other canals connect it with the interior. Its export trade includes grain, dairy produce, cattle, tallow, wool, hides, etc.; and it imports coal, timber, wine, and colonial produce. A considerable number of vessels are built here annually; and the manufactures include leather, paper, wire ropes, bricks, soap, and tobacco. There are also oil-mills, breweries, and distilleries. Pop. (1900) 16,453.

Emelé, ā-mā-lā, **Wilhelm,** German painter: b. Buchen, Odenwald, 1830. He first adopted a military career but studied art with Dietz at Munich, and later at Antwerp and Paris. His canvases are noted for exactness of details, his subjects being military. He has lived in Vienna since 1861. Among his works are: 'Battle of Stockach'; 'Capture of Heidelberg Bridge in 1799' (1857); 'The Fight Near Aldenhoven' (1859); 'The Square of the Battle of Aspern' (1860); 'Capture of Camp Near Farmars'; 'Attack on the English by French Cuirassiers at Waterloo'; 'Battle of Wurzbourg' (1867), his best work; 'The Archduke Charles at Battle of Neerwinden' (1872); 'Attack of the Bournernain Division Near Elsasshausen'; 'Battle of Dijon'; 'Meeting of Patrols of Seventh and Fourteenth Corps, Prussian Army, Near Vesoul'; 'Headquarters of 14th Army Corps in Battle of Belfast'; 'Episode of Battle of Worth'; 'Victory of George II. over the French at Dettingen' (1879).

Emerald (O. Fr. *emeraude*, Gr. σμάραγδος), a gem of pure green color, often very rich and beautiful. It is a variety of the mineral beryl and is, therefore, a silicate of aluminum and glucinum (q.v.), its green color being due to the presence of a little chromium. It is usually found in nodules or in distinct six-sided prisms of the hexagonal system. It is a little harder than quartz, and has a specific gravity of about 2.69. It is not acted on by acids. Many of the most intensely colored and valuable emeralds that we are acquainted with were brought from Peru, the largest from Takowaja, in the Urals, a specimen of which is seen in the 6¾-pound stone at St. Petersburg. Most modern emeralds come from the Republic of Colombia, which quite supplies the current market. In the United States emerald crystals up to nine inches in length and of rich color have been found in Alexander County, N. C., while extensive mining in Mitchell County, N. C., has yielded beautiful gems and much so-called "emerald matrix." The rarity, rich color, brilliancy and hardness of emerald have made it one of the most highly prized of gems. "Oriental emerald" is green sapphire, "lithia emerald" is hiddenite (q.v.), "Uralian emerald" is demantoid, "Brazilian emerald" is tourmaline (q.v.). See also BERYL and GEMS.

Emerald Green, known also as **Schweinfurth** or **Paris Green,** and by a great number of other names, is one of the most beautiful green pigments. It appears to contain copper, arsenic, and acetic acid, and is usually regarded as an aceto-arsenite of copper. It is a crystalline powder, which becomes paler by grinding, is not affected by light and air, and is insoluble in water, but is decomposed by alkalies. It is used both as a water and as an oil color, and is used for tinting wall-papers, though with much less frequency since the danger of that practice has been discovered.

Emerald Isle, an epithet applied to Ireland, from the freshness and bright color of the verdure, produced by the abundant heat and moisture continually reaching it from the Atlantic. This epithet was first used by Dr. W. Drennan (1754–1820), in his poem entitled 'Erin.'

Emerson, Charles Wesley, American educator: b. Pittsfield, Vt., 30 Nov. 1837. Studying law, medicine and theology, he was a clergyman for many years. He founded the Emerson College of Oratory, Boston (1880), and has since been its president, teaching oratory, physical culture and voice development.

Emerson, Edward Waldo, American physician and author: b. Massachusetts 1844. He is a son of Ralph Waldo Emerson (q.v.). He was graduated at Harvard College and Harvard Medical School, and is an instructor in anatomy at the Boston Museum of Fine Arts. He has published: 'Emerson in Concord' (1888); and an edition of the 'Correspondence of John Stering and Ralph Waldo Emerson, with sketch of Sterling's Life.'

Emerson, MRS. **Ellen** (RUSSELL), American author: b. New Sharon, Maine, 16 Jan. 1837. She was married to Edwin Emerson (1862). Her works are: Indian Myths, Legends and Traditions' (1884); 'Masks, Heads, and Faces, with Considerations Respecting the Rise and Development of Art' (1891); 'Nature and Human Nature' (1901); 'The Story of the Vine' (1902).

Emerson, George Barrell, American educator: b. Kennebunk, York County, Maine, 12 Sept. 1797; d. Newton, Mass., 14 March 1881. He was graduated at Harvard College (1817), and was the tutor in mathematics and natural philosophy there (1819–21). In 1823 he opened a private school for girls in Boston, which he conducted until 1855, when he retired from professional life. He wrote the second part of the 'School and Schoolmaster,' of which the first part was written by Bishop Potter of Pennsylvania. He was appointed chairman of the commissioners for the zoological and botanical survey of Massachusetts, in which capacity he published a 'Report of the Trees and Shrubs Growing Naturally in the Forests of Massachusetts' (1846).

Emerson, Luther Orlando, American composer: b. Parsonsfield, Maine, 3 Aug. 1820. He studied music and later taught for eight years in Salem, Mass. He then served as organist and musical director in various churches in Massachusetts, and was the director of about 300 musical festivals and conventions. He has published: 'The Romberg Collection' (1853); 'The Golden Wreath' (1857); 'The Golden Harp' (1858); 'The Sabbath Harmony' (1860); 'The Heart of Judah' (1863); 'Jubilate' (1866); etc.

Emerson, Oliver Farrar, American educator: b. Traer, Iowa, 1860. He studied at Iowa College, taking a post-graduate course at Cornell University. After serving as superintendent and principal of schools in Grinnell and Muscatine, Iowa, he was principal of the Academy of Iowa College (1885–8); instructor in English (1889–91) Cornell University, and assistant professor of rhetoric and English philology in the same institution (1892–6), when he took the same chair in Western Reserve University. He is secretary of the American Dialect Society, and is a regular contributor to philological papers. He has published: 'History of the English Language' (1894); 'A Brief History of the English Language' (1896); an edition of 'Dr. Johnson's Rasselas' (1895); and 'Memoirs of the Life and Writings of Edward Gibbon' (1898).

Emerson, Ralph Waldo, American poet and philosopher: b. Boston 25 May 1803; d. Concord, Mass., 27 April 1882. The celebration two years ago, in 1903, of the 100th birthday of Ralph Waldo Emerson served as a meter to mark how wide and deep was the influence which a single original thinker gifted with literary expression can exert at the end of his first century; for there was public recognition of his ethical and poetic genius in every quarter of the globe. Along with this appreciation went also the perception that a distinct Emersonian school of thought had arisen, modified in some degree by the circle of striking writers and talkers — men and women of thought, fancy, imagination, and eloquence — who gathered around Emerson early or late in his career and now constitute the group known as the "Concord Authors," or the Concord School of Philosophy. Most of these at one time or another lived in the rural village of Concord in Massachusetts, where Emerson spent a half century of his life. Such were Alcott, Hawthorne, Thoreau, Ellery Channing, Louisa Alcott, George William Curtis, Elizabeth Hoar, Elizabeth Peabody, Julian Hawthorne, J. W. Chadwick, W. T. Harris, John Albee, F. B. Sanborn, F. P. Stearns — all of whom lived for longer or shorter times in Concord; and on the outside of the circle, yet not far away, Margaret Fuller, Theodore Parker, Dr. Bartol, David Wasson, Mrs. Ednah Cheney, Christopher Cranch, and John S. Dwight. All these stood in relations more or less direct to Emerson, and were influenced in varying degrees by his fertilizing mind and gentle social attraction. Several of them, as Hawthorne, Thoreau, Channing, Margaret Fuller, and Alcott, were as original as Emerson, though less gifted with the qualities that form a school or coterie; and none of them could properly be styled satellites or Emersonidæ, although that term has been applied to several of them. Emerson was the eldest born of all these, except Alcott. He was the son of a Boston pastor, Rev. William Emerson of the First Church, which had become Unitarian instead of Calvinistic. Most of his male ancestors as far back as the English Reformation were clergymen, and his middle name, Waldo, was said traditionally to come from one of those Waldenses who incurred the censure of the popes as heretics far away in the Middle Ages. His oldest American ancestor founded the Christian Church in Concord in 1635 (Rev. Peter Bulkeley) and by that line Emerson was related to the noble English family of Saint John, of which was Pope's brilliant friend Bolingbroke. From another clerical ancestor, Rev. William Thompson, through the Cogswells, he was related to Wendell Phillips, Phillips Brooks, and other men famous for eloquence; and by another line he descended from a clerical family of Moodys, whose genius verged upon insanity. This last name was perpetuated in Emerson's aunt, Mary Moody Emerson, his father's sister, who had more to do with his intellectual and spiritual training than any other of his early instructors. With this strong clerical bent in his ancestry young Waldo Emerson was destined to the pulpit from his cradle, and was carefully educated in Boston and Harvard College with that view. He entered college early and came under eminent teachers, Edward Everett in Greek, George Ticknor and Edward Channing in literature, and Caleb Cushing in mathematics — but for the last-named study he had no inclination, and did not stand high in general scholarship at his graduation in 1821. He read widely, however, and the discipline of teaching in his elder brother William's school for young ladies at his mother's house in Franklin Street, Boston, gave him exactness in Latin, French, and Greek. He presently (1823) took up the study of divinity with Dr. Channing and Prof. Andrews Norton, and began to preach sermons in 1827. He spent much time in youth at his grandmother's, who owned the Old Manse in Concord, and there he preached for some months in 1828, during the absence of her second husband, Rev. Dr. Ripley. His own grandfather, Rev. William Emerson of Concord, who built the Old Manse, died as a chaplain in the Revolutionary army in 1776.

The clerical life of Emerson was a distinct era, marked by originality and independence in the young divine. His first and only settlement was at the Second Church of Boston, which had been Cotton Mather's, and was Henry Ware's when Emerson was ordained as a colleague in 1829. He became sole pastor in 1830, and in the meantime had married a delicate young Bostonian, Ellen Tucker, who died in 1832. In 1833, upon a point of doctrine con-

RALPH WALDO EMERSON.

cerning the rite of the Lord's Supper, in which he found himself at variance with his deacons, he preached a sermon gently setting forth his scruples and resigned his place, much against the wish of his people. But he was ill and despondent since the death of his wife and the illness of his brother Edward; and a foreign tour was prescribed for him, which broke the continuity of his preaching, although he continued to officiate in pulpits here and there for some six years after his first visit to Europe. Miss Elizabeth Peabody, who had often heard Emerson preach, said at the Concord School of Philosophy in 1883:

> From 1834 I never omitted an opportunity of hearing Emerson preach. I sought and obtained leave to read the sermons he had in manuscript. They were all as truly "transcendental" as any of his later writings in prose or verse. If a volume of them could be printed to-day in their own form it would interpret his later revelations, of which they are but a varied expression. From first to last he never shut in his vision of the living God to the limitations of his own or any other individual conception. I once repeated to him the reply of an unconsciously wise and pious woman of the Lexington congregation, when asked why they did not settle an eminent preacher (Dr. Hedge). "Oh, we are a very simple people in East Lexington; we can hardly understand anybody but Mr. Emerson." He did not laugh; on the contrary, with an accent almost pathetic, he replied, "If I had not been cut off untimely in the pulpit, perhaps I might have made something of the weekly sermon."

No doubt he would have made much of it. But what he did was better; he turned the lecture desk into a pulpit, and for more than 30 years preached righteousness there. From 1835, the date of his second marriage, to Miss Lidian Jackson of Plymouth, lecturing was his chief occupation during half the year. His essays were first lectures and were generally given to many audiences before he thought them good enough to print.

His first book, 'Nature,' published in a small edition in 1835, was not a course of lectures, but rather genuine essays, thought out for years, and mostly written out in their final form at the Old Manse, or finished in his own study at the home he made for himself in 1835 at the east end of Concord village, and where he died, 27 April 1882. The book attracted little notice in America or England at first, and a second edition was not issued until 1849, a dozen years having been required to sell 500 copies. But Carlyle, whom he had visited at Craigenputtock in 1833, and with whom he formed then a strict friendship and corresponded until Carlyle's death, saw its value, and so did Alcott, Hawthorne, Parker, Thoreau, and a circle of high-minded women, who became his constant hearers. It now takes rank as the nearest approach to a system of philosophy which he put forth in successive chapters during his whole active life. He planned another and more elaborate work, which he called 'The Natural History of Intellect,' and of which he wrote several chapters, intended to set forth the function and operation of the qualities of the human mind — memory, imagination, reason, volition, etc.— but he never brought it to such completion that it could be published as a whole, either by himself or his successive editors, Mr. Cabot, Dr. Emerson, etc. When invited to lecture on Philosophy at Harvard, as he was in 1870, he threw these chapters and copious notes and readings into 18 lectures, two in a week, but the effort was too great for him at his age and in his failing strength, and he could never afterward bring the papers into form for printing. Several of the chapters appear separately; and perhaps some future scholar may combine them with 'Nature' into a single work.

Emerson was actually introduced to noisy public notice by two of his early addresses, which are now printed in the same volume with 'Nature' — his Phi Beta Kappa oration of 1837, and his Divinity School Address of 1838. The first attracted attention and praise, mingled with surprise; the second, from its bold appeal to preachers to revise their theology and meet their hearers with original truths, not with traditional forms of religion, aroused the native intolerance of New England to shrill protest and uncharitable malediction. His own college, of which he was the most illustrious graduate, drew back in timid aversion from thoughts alleged to be revolutionary, and it was not until 1867, 30 years after his first Phi Beta oration, that he was again invited to address the student-body, or to receive any collegiate honor. About the same time (1837–8) he identified himself with the unpopular cause of negro emancipation, with the advanced ideas of Alcott in education, and with several schemes of social reform, which the commercialism of the period viewed with dislike or scornful indifference; and so he alienated another class in the New England and New York communities, who might otherwise have been charmed with his literary skill and his peculiar eloquence. Thus his audiences continued small, and his writings had little general circulation, until the gradual education of people in his ideas and his phraseology, gave him the hearing that his genius deserved.

Meanwhile Emerson was drawing about him in Concord and Boston, in Plymouth, Salem, and other New England towns, a circle of friends and a school of thought. The number of these persons was small at first, but their enthusiasm was fervent, and their intellectual and social force was considerable. Prominent among them was Margaret Fuller, a woman of genius who drew other women by her talent and her sympathies, and who had formed a circle of her own in Cambridge and Boston. Among men, the most prominent for a time was Bronson Alcott, an educational reformer, who had shown insight and eloquence in dealing with the young, but whose talent for conversation was not accompanied by any corresponding gift of expressing himself in writing. Others of the circle were F. H. Hedge, an accomplished student of German literature, afterward distinguished in theology; Dr. Convers Francis, a learned pastor and professor at Cambridge; Theodore Parker, equally learned and more radical in opinion; with younger men like William Henry Channing, James Freeman Clarke, Henry Thoreau, Wentworth Higginson, Ellery Channing, S. G. Ward, Marston Watson of Plymouth, J. Elliot Cabot; and in his own immediate acquaintance, Mrs. Sarah Ripley, the most learned woman of New England, who had married Emerson's uncle, Rev. Samuel Ripley; her brother, George Bradford; Miss Elizabeth Hoar, an accomplished woman, betrothed to Emerson's brother Charles (who had died in

1836), and Emerson's own aunt, Mary Emerson, who at times favored and at times opposed the movement in which her nephew was engaged. This movement presently was called, rather than called itself, "Transcendental"— the term borrowed from the phraseology of German philosophy, but hardly corresponding in New England to the meaning it had in Germany, and indeed used loosely in America with no fixed meaning. Its followers were in fact idealists of various shades and divisions of thought and speculative philosophy, whose organ, the quarterly review called 'The Dial,' existing four years (1840-4), became the receptacle of much youthful literature and many earnest essays toward the reformation of society in education, morals, and politics. Its first editors were Margaret Fuller and Rev. George Ripley, the founder of the famous community at Brook Farm; but from the first Emerson had great influence in its councils, and ultimately became its proprietor and editor, associating Thoreau with himself in editing it. Hence much of the earlier writing of Thoreau first came out in 'The Dial,' as did that of Emerson and Margaret Fuller and Theodore Parker. For this review Emerson wrote the introductory essay, as he did in December 1847 for a kindred venture, the 'Massachusetts Quarterly Review,' in which Parker and Elliot Cabot were frequent writers. In these two brief essays must we still look for a characterization of the so-called transcendental movement, so unimportant in its first appearance, yet so momentous afterward in determining some of the chief results of the Civil War of 1861-5. In 'The Dial' Emerson spoke of it as "the progress of a revolution," and such it proved indeed to be. He added:

> Those who share in it have no external organization, no badge, no creed, no name. They do not vote or print, or even meet together. They do not know each other's faces or names. They are united only in a common love of truth and love of its work. . . . Without concert or proclamation of any kind, they have silently given in their several adhesion to a new hope; and in all companies do signify a greater trust in the nature and resources of man than the laws or the popular opinions will well allow.

Seven years later, approaching the same topic from another point of view, and with more experience of his countrymen, Emerson said in the first number of the 'Massachusetts Quarterly':

> The aspect this country presents is a certain maniacal activity, an immense apparatus of cunning machinery, which turns out at last some Nuremberg toys. Has it generated, as great interests do, any intellectual power? One would say there is nothing colossal in the country but its geography and its material activities; that the moral and the intellectual effects are not on the same scale with the trade and production. . . . It is a poor consideration that the country wit is precocious, and, as we say, practical; that political interests on so broad a scale as ours are administered by little men with some saucy village talent; by deft partisans, good cipherers, strict economists, quite empty of any superstition. . . . The state, like the individual, should rest on an ideal basis. As soon as men have tasted the enjoyments of learning, friendship, and virtue — for which the state exists — the prizes of office appear polluted, and their followers outcasts.

The profound discontent so manifested, yet lightened by an ideal hope of better things, was working in the mass of the Northern people, as well as in this small nucleus of Platonists and agitators of New England, New York, and Ohio. While 'The Dial' had to perish for want of subscribers, the *Tribune* of New York rose up to more than fill its place; and Margaret Fuller, Thoreau, George Ripley, and George William Curtis found Greeley ready to give them a hearing in his daily and weekly newspaper, which had readers everywhere. It reported Emerson's lectures, the sermons of Parker, and printed the higher criticism of Ripley, Dana, and Margaret Fuller. Political parties began to be formed on ideal issues, and courageous minorities began to grow into triumphant majorities here and there.

In this escape out of the ideal into the practical Emerson rather unwillingly found himself involved. He began to be popular, and his books, which up to 1850 had scarcely paid for the cost of publishing them, became a source of moderate income. He had followed up the publication of essays in 'The Dial' by the issue in 1841 of a volume selected from his earlier lectures and essays, a second series in 1843, a collection of his orations annexed to a reprint of 'Nature' in 1849, and in 1850 his most effective book for European recognition of his high quality, the 'Representative Men.' All these books had been lectures mainly, though much changed in publication, as may be seen by reading the omitted passages cited in the 'Notes' to Dr. Emerson's 'Centenary Edition' of his father's books, issued in 1904. And by 1850 Emerson had become a widely-sought lecturer, and went as far west as Galena and Saint Louis, though practically shut out of the slave-holding States by his pronounced anti-slavery opinions, which began to be made public by him in 1844. This wider hearing as lecturer was needful to him now pecuniarily; for his small fortune, which had made him independent since 1832, had become involved in railroad speculations by the ambition of a classmate at college, and yielded him little revenue for years. The way had been prepared for his extended reputation in England and on the continent by his visit there in 1847-8, when he lectured extensively in England and Scotland under arrangements made for him by Alexander Ireland of the Manchester 'Guardian,' and by his friend Carlyle and others in London. He had even aroused the envy of Mrs. Carlyle by his welcome in England among the aristocratic circle to which he had access through his friends George Bancroft and Charles Sumner, as well as by the simple dignity of his own manners, which admitted him everywhere in the exclusive society of great cities. On this visit he saw something of the French revolution of 1848, and made acquaintance in England with Arthur Hugh Clough, Matthew Arnold, Froude, and others of the rising young men in literature, as well as the older men of letters whom he met at the breakfasts of Rogers, and in the circle to which Carlyle, long resident at Chelsea, belonged.

Emerson had ever been more forward to publish his friends' books than to hasten to the press with his own. The first edition of 'Sartor Resartus' in America was introduced by him in a preface, and he took charge later of American editions of the 'French Revolution,' and the earlier essays of Carlyle; by all which the author received, from sales in America before 1842, about $1,000, which he assured Emerson was more than he had then got from his books (not his review articles) in Great Britain.

1. Home of Emerson at Concord, Mass. 2. Library in the Emerson Home.

Emerson also edited the first edition of Jones Very in 1839, and promoted the earlier volumes of Ellery Channing and Thoreau from 1840 to 1854, when Thoreau issued the second of the only two volumes published in his lifetime. Altogether, for Carlyle, Margaret Fuller and his other friends, he had caused to be printed three times as many volumes as appeared of his own writing during the 20 years after his second marriage in 1835. In 1852, while in the midst of his lecturing popularity, he paused at Buffalo, N. Y., from one of his extended tours, to urge on his friends at Plymouth to gratify the ambition of Ellery Channing, who would figure as a lecturer as well as a poet. Emerson wrote then to Marston Watson, the «Plymouth Evelyn,» as Alcott styled him, thus (4 Jan. 1852):

Mr. Scherb is a very proper person to take a part in your series of Sunday lectures, and will gladly do so. One other person I should like well to have engaged, my friend Ellery Channing. But I dare not quite say he has any lecture for your purpose, until I hear his lecture on the 'Future.' Both the others of his three I have heard; and though they are full of wit and criticism or sarcasm all round the compass, he needs practice and pruning. I am sorry on his very account to leave home just now; for I wish more that he should lecture than that I should.

As a poet Emerson had been slightly known to his youthful associates in college and elsewhere, and in 1834 he had been invited to write the customary poem for the Phi Beta Kappa anniversary at Harvard, and did so. But he was dissatisfied with it, and for some years after did not publish verses. In 1837 he sent to his friend J. F. Clarke at Louisville, Ky., for printing in the 'Western Messenger' of Louisville and Cincinnati, three poems of his earlier composition, and he continued to print others in 'The Dial.' In 1846 he collected these and others in a small volume, printed in Boston and London in 1847, and he issued another volume, largely made up from contributions to the 'Atlantic Monthly,' in 1867. His son has added many poems and fragments in the final edition, so that it is now possible to judge of Emerson as poet by a perusal of all that he wrote in metre. At first his verse attracted little attention, except by parodists who viewed it as something comical, and to be satirized; this he had expected, for it had happened with his prose also. But even those who admired and quoted his poetical prose were rebuffed by his irregular and difficult verse; and only some 20 years after the volume of 1847 did it begin to be recognized that here was a philosopher putting his thought into oracular verse, some of which was becoming proverbial, as oracles are wont to be. Since 1884, when at the summer session of the Concord School of Philosophy, this feature of his poetry was set forth, it has become a fashion to interpret it in readings; and the essence of his deeper philosophy is best given in his verse; a key to the whole Emersonian theory of the universe being found in the oracular 'Sphinx' of the first 'Poems,' where it stands at the beginning, as befits a key. Besides this philosophic quality, there is also much of a high literary character in single poems devoted to love, friendship, patriotism, and the cause of liberty.

Had it been predicted in 1847, when Harvard professors were scoffing at Emerson's verse, and declaring his philosophy unintelligible, that 60 years later Harvard would be teaching philosophy in a spacious hall named for Emerson and built in part by the contributions of his followers and friends, the prophecy would have been classed with almanac presages of the weather. Yet that very thing has happened, and happened partly in consequence of the 10 years' continuance, from 1879 to 1888, of the summer school of philosophy and literature just mentioned. This school carried out an early dream of Emerson and Alcott, who both took part in it till Emerson's death in April 1882, and Alcott's stroke of paralysis in the following October. It brought together speculative men of different schools, all in their way idealists, and it raised into prominence Emerson's share in quickening and deepening philosophic ideas in America.

Emerson had published his 'English Traits,' a masterly summary of English history and character, in 1856; in 1857 he became a leading writer for the new 'Atlantic'; in 1860 published the 'Conduct of Life'; in 1864 'Society and Solitude'; in 1874 a selection of poems (omitting his own) called 'Parnassus'; and in 1876 'Letters and Social Aims,' edited by his subsequent biographer, Elliot Cabot. During the Civil War he was a frequent orator for the Union and emancipation, and his political speeches have been posthumously collected in a volume of 'Miscellanies,' published in 1883, and enlarged in the Centenary edition. A volume of 'Lectures and Biographical Sketches' (1883 and 1904) gives his posthumous lectures and personal tributes, and a final volume (1893 and 1904), 'Natural History of Intellect,' gives others, and a general index, long needed.

The classification of topics in these later books does not well agree with the titles; and there are still other volumes promised from Emerson's journals and letters, although these have been much drawn upon in notes to the 12 volumes already issued. It remains for some future editor to arrange the writings with a better regard to their chronological sequence; since the estimate of Emerson as a writer depends somewhat on the observed growth and decline of his powers, as in the analogous cases of Plato and Goethe.

It is in the class with these two world-renowned authors that Emerson will stand hereafter. Less copious and less imaginative than either Plato or Goethe, he is not less original than they; and his expression of profound thought and ethical truth was guided by a taste often better than theirs. Much mannerism and many repetitions are found in his books as in theirs; many apparent inconsistencies also, as with them. But these last grew out of the development of his thought, and his increasing perception of the complexity of the two worlds, Nature and Man. Of his many biographers and critics few have fully comprehended him; they furnish material for final judgment rather than a statement to satisfy future readers. The best, in this view, are Elliot Cabot and Dr. Emerson, to whom the world is indebted for much material drawn from the manuscripts, and not found in type elsewhere.

Emerson's health and vigor failed after the partial burning of his house in 1872, and his last tour abroad, in 1872–3, did not restore him. He continued active for years, though withdrawing more and more from publicity, by reason of his failing memory. His virtuous and serene nature remained unshaken by these accidents of mortality, and his final illness, though pathetic from his anxiety to avoid burdening others, was short and hardly afflictive. His wife and three of his four children survived him — Mrs. Emerson, the mother of all, dying in 1892, at the age of 90. His descendants are numerous by various names; his friends are numberless, for he never had a personal enemy, and he inspired affection almost as much as admiration.

Bibliography.—Memoirs of Emerson in various forms began to appear even before his death in 1882, the first good one being by G. W. Cooke (Boston 1881), 'Ralph Waldo Emerson, His Life, Writings and Philosophy'; followed in 1882 by Alcott's last book, 'An Estimate of Emerson's Character and Genius in Prose and Verse.' In 1883, supplemented in 1885, appeared 'The Correspondence of Carlyle and Emerson,' edited by Prof. C. E. Norton, containing much not found in any biography of either. 'The Genius and Character of Emerson, Lectures at the Concord School of Philosophy' (Boston 1884), contains estimates by 12 or 15 literary and philosophic friends. The authentic biography is 'A Memoir of Ralph Waldo Emerson' by J. Elliot Cabot (Boston 1887); the best brief biography is Dr. Richard Garnett's 'Life of Ralph Waldo Emerson' (London 1888). Dr. E. W. Emerson's 'Emerson in Concord, a Memoir' (Boston 1889), is a supplement to Cabot's memoir, dealing chiefly with Concord incidents. The largest recent addition to our knowledge of Emerson's life and writing is found, however, in Dr. Emerson's 12 volumes of the Centenary edition of 1904, containing at least 1,000 pages of new matter, with many dates and incidents not elsewhere recorded (Boston 1903–4). An extensive literature concerning Emerson exists in French, German, and Italian, and he is studied to some extent in Scandinavia, Russia, Greece, Persia, and India. The autobiographies of M. D. Conway and A. D. White (1904 and 1905) contain something on these points.

F. B. Sanborn,
Author of a 'Life of Emerson.'

Emerton, Ephraim, American historian: b. Salem, Mass., 18 Feb. 1851. He was graduated at Harvard 1871 and studied in Leipsic, becoming instructor in Harvard 1876, and professor of ecclesiastical history there 1882. His works include: 'Synopsis of History of Continental Europe'; 'The Study of Church History'; 'The Practical Method in Higher Historical Education' (1885); 'An Introduction to the Study of the Middle Ages' (1888); 'Mediæval Europe' (1894); 'Desedirius Erasmus'; 'Heroes of the Reformation'; 'Sir William Temple und die Tripleallianz vom Jahre, 1668.'

Em'ery, an impure variety of the mineral corundum (q.v.), reddish brown, black, blue black or gray in color, and next to the diamond the hardest mineral known. It consists of nearly pure alumina (65 to 75 per cent) and oxide of iron, and a small amount of silica and water. Emery occurs in large boulder-like masses, closely resembles a fine-grained magnetite ore in texture, and is often mistaken for it. In its native form its value as an abrasive has been known from the earliest times, and many references are made to it in books by Greek authors. Then as now it was used in cutting and polishing jewels and intagli, in the sculpture of statuary from the harder rocks, and in polishing marble. It was undoubtedly used by the Egyptians, and there are many evidences of the use of it or as hard a substance in the manufacture of prehistoric stone implements.

As now used, in its pulverized form, it is one of the most useful substances known to the arts. The rock is broken in powerful crushers and stamping-mills and separated into powders of varying degrees of fineness by screens or by elutriation. These powders, varying from particles one tenth of an inch in diameter to the finest flour, are sprinkled with water or oil upon the lead wheel of the lapidary, or spread upon wood, paper, or cloth to which a thin layer of glue has been previously applied; or as has been found to be its most effective application, mixed with various adhesive substances and molded into solid wheels. Emery-stones of various shapes and sizes are also made in the same manner.

Emery wheels are now made up to 36 inches in diameter and from 4 to 6 inches in thickness, and in every variety of coarseness from rough shapers to fine polishers for brass and steel. The cementing material is usually a secret with the manufacturer, and upon this and upon the quality of emery used depends the cost and the subsequent life and usefulness of the wheel. Properly mounted and turned at a proper speed it is our most effective cutting tool, tearing its way rapidly into chilled castings that the best file will not cut, or taking the teeth instantly off the hardest file. Special points to be observed are uniformity of texture, that the wheel may wear away evenly under use; carefully fitted bearings, that there may be no vibration under the high speed at which it is run; the wheel must not be fitted closely to either mandrel or flanges, lest expansion by heat burst the wheel; and the cementing material of the wheel must be able to resist the tendencies to centrifugal disruption and to melting under the heat generated by its friction with the object being cut. Its effective speed must have been determined and tested and the degree of pressure with which the work is to be applied must likewise be ascertained. Emery wheels that have become misshapen through use are turned true by various special contrivances, all of which must have a cutting edge of rough diamond. Wheels are often shaped for special work in the same manner.

The present supply of emery is chiefly from the island of Naxos and from near Smyrna, Turkey. A small amount is mined near Chester, Mass., and it is found in insignificant quantities elsewhere in the United States. Corundum and precious sapphire have been found in Georgia and North Carolina.

Emesa, an ancient town, now called Hems. See Hems.

Emetic, any agent used to induce vomiting. In medicine the emetics that are used are now few in number. The main object to be attained by their use is to empty the stomach of irritating or poisonous contents. As most emetics act strongly on the sympathetic nervous system, they also cause muscular relaxation, dilated arteries, and a sense of weakness, amounting at times to collapse. Emetics are usually classified as local or as systemic — those acting directly on the stomach-walls, such as lukewarm water, mustard, alum, and the more violent corrosive metallic salts, or those, as copper sulphate, whose influence is exerted on the central nervous system, after first being absorbed into the blood. Of these tartar emetic, ipecacuanha, and apomorphine are examples. Emetics should be given with caution. In children particularly the stronger emetics often cause great prostration, and if a child be suffering from a disease that causes heart weakness, such as diphtheria, emetics are not advisable. In cases of poisoning emetics should be promptly given, but washing out the stomach by means of a flexible rubber tube is preferable. It is sometimes justifiable to give emetics when there seems to be danger of asphyxiation from retained mucus in the bronchial tubes. The relaxation following emesis is sometimes remarkable. See POISONING; VOMITING.

Em'etine, an alkaloid occurring in ipecacuanha, and constituting its chief active principle. Its chemical formula has not been established with certainty, but is considered to be $C_{30}H_{40}N_2O_5$. Emetine is sparingly soluble in water and in ether, though it dissolves readily in alcohol, chloroform, carbon disulphide, and various essential oils. It is white in color, but is turned to a yellow by the action of sunlight. When taken internally in considerable doses it acts as a powerful emetic, to which circumstance it owes its name.

Emeu. See EMU.

Emigration. See IMMIGRATION.

Emigrés, ā-mē-grā, a French term for those who have been compelled to leave their country on account of religious persecutions, as did the Huguenots, for instance, in the 17th century, or for some other causes. The term, however, is now most commonly applied to those Frenchmen, many of them of noble family, who left France at the commencement of the first French Revolution. Most of these emigrés hoped to see the restoration of the old order, by which they might be enabled to return to their country, and therefore remained at first on the frontiers. It would be harsh, perhaps, to call all those who left their country to its fate in the time of its greatest peril, weak and timid, but the emigration deprived France of the conservative element at the time the country stood most in need of it. The emigration of the royal princes can hardly be justified. Their presence was of great importance to the state, and their example contributed not a little to the extensive emigration which followed, and the injurious consequences which attended it. At the head of the emigrants stood the royal princes of Condé, Provence, and Artois, the first of whom collected a part of the fugitives to co-operate with the allied armies in Germany for the restoration of the monarchy. At Coblentz a particular court of justice was established to settle causes relating to the French *emigrés.* But the invasion of the Netherlands by Dumouriez drove them from these provinces in mid-winter in a deplorable condition, while their number was daily increased by the system of violence and terror carried on in France. The corps of Condé was finally taken into the Russian service, and was disbanded in the Russian-Austrian campaign in 1799. When Napoleon became emperor it was one of his first acts of grace to grant permission to all but a few of the emigrants to return to their country, but by the terms of the charter of 1814 they were precluded from regaining either their status or their ancient privileges. During the Restoration period they persistently petitioned Louis XVIII. and subsequently Charles X. for reinstatement and indemnification, but though a government grant was made for their compensation, the measure was rendered abortive by the July revolution.

Emile, ā-mēl, a famous pedagogic romance by Jean Jacques Rousseau, published 1762, and named from its principal character. Its immediate effect was to call down on his head the denunciations of the Archbishop of Paris, who found him animated "by a spirit of insubordination and revolt," and to exile him for some years from France. Its lasting effect was to lay the foundation of modern pedagogy. Due to the suggestion of a mother who asked advice as to the training of a child, it was the expansion of his opinions and counsels; the framework of a story sustaining an elaborate system of elementary education. Emile is reared apart from other children under a tutor, by a long series of experiments conducted by the child himself, often with painful consequences. Little by little, his childish understanding comes to comprehend at first-hand the principles of physics, mechanics, gardening, property, and morals. From the hints contained in 'Emile,' Basedow, Pestalozzi, and Fröbel drew their inspiration and laid the broad foundations of modern elementary education.

Emilia, ā-mēl'ē-ä, a compartimento of Central Italy, comprising the provinces of Bologna, Ferrara, Forli, Modena, Parma, Piacenza, Ravenna, and Reggio Emilia. The name is derived from the ancient Via Æmilia, a continuation of the Via Flaminia, which passed through these territories. Area 7,920 square miles; pop. 2,451,803.

Emin Pasha, ā'mēn păsh-â', or păsh'a (EDUARD SCHNITZER), African army surgeon, governor and explorer: b. Oppeln, Prussia, 28 March 1840; d. 1892. He was educated at Breslau, Berlin, and Konigsberg, going to Turkey in 1864, and being appointed surgeon in the Turkish army 1865. In 1875 he went to Egypt, becoming surgeon-general of the Egyptian army under Gen. Gordon, who made him governor of the equatorial provinces in Sudan. He made several exploring expeditions, giving to the world much information in reference to the fauna and flora of that region, together with much geographical knowledge. He was cut off from relations with the rest of the world by the insurrection of the dervishes under the Mahdi in 1883, although maintaining his position. The Egyptian government made him a pasha 1887. Rescued by Stanley in 1888 he entered the service of the German East Africa Company in 1890. He went with Dr. Stuhlman to East Africa upon an exploration expedition and was assassinated by Arabs.

Emine, Nikita Ossipovich, nē-kē'tä ŏs-sē-pō'vēch ĕm'ē-nē, Armenian historian: b. near Ispahan, Persia, about 1815; d. Moscow, Russia, 7 Jan. 1891. He was educated at the Lazareff Institute for Oriental Tongues, and at the University, Moscow. Russian learning is indebted to him for his translation into Russian of all the Armenian historians. His monumental work, a 'History of Armenia,' was translated into French.

Eminence, as a designation of cardinalitial dignity, is of comparatively recent introduction; it dates from the 17th century. Down to that time the cardinals were addressed by the titles Most Illustrious (*Illustrissimus*), and Most Illustrious Lordship (*Illustrissima Dominatio*); but in 1630 Pope Urban VIII. promulgated a decree, drawn up in accordance with a report of the Congregation of Rites, substituting for the previous formulas Most Eminent (*Eminentissimus*), and Eminence (*Eminentia*), respectively. No dignitary but a cardinal (or by exception the Grand Master of the Knights Hospitallers of the Order of St. John of Jerusalem) was to be addressed in this form. Further, a cardinal was to ignore any communication addressed to him in any other form; and any prelate who assumed the title Eminence, or Most Eminent, was made liable to penalties.

Eminent Domain, the power of the state to appropriate private property for public use on payment of just compensation to the owner. A superior right of property subsists in a sovereignty, by which private property may, in certain cases, be taken, or its use controlled, for the public benefit, without regard to the wishes of the owner. This highest and most exact right of property is immanent in the government, or in the aggregate body of the people in their sovereign capacity, giving the power to resume the possession of the property, in the manner pointed out by the constitution and the laws of the various states, when the public good requires it. There seems to be no objection to considering this right, theoretically at least, as so much of the original proprietorship retained by the sovereign power in granting lands or franchises to individuals or corporations, wherever the common law theory of original proprietorship prevails. Extraordinary and unforeseen occasions arise in cases of extreme necessity in time of war, or of immediate and impending danger, in which private property may be impressed into the public service, or may be seized and appropriated to the public use, or may even be destroyed, without the consent of the owner. The power exists only in cases where public exigency demands its exercise. It makes no difference whether corporeal property, as land, or incorporeal, as a franchise, is to be affected by the exercise of the right.

Eminescu, ā-mēn-ĕs'koo, **Michael,** Rumanian lyric poet: b. Botuschani 1849; d. Bucharest 27 June 1889. He was for a time editor of 'The Times,' a strong Conservative journal, and the fierceness of political strife would seem to have spoilt his fine poetical genius. He died in a madhouse. His fame rests on his first volume of 'Poems'; they are mostly elegio-satiric, and touch questions political, social, religious, and moral.

Emir, ē'mėr, or **Emeer,** ē-mēr' (that is, noble, princely), a title of honor given in the East and in North Africa to those who claim descent from Mohammed and his daughter Fatima. These emirs are found in Arabia, where they are the chieftains of the Bedouins. Their origin, however, is doubtful. In Turkey they form a kind of hereditary nobility, and wear as a badge a green turban, as Mohammed is said to have done. They have certain privileges, but otherwise no higher claims to civil offices than other Mussulmans. The word emir is also applied to certain offices and employments, for example, *emir hadji,* conductor of the pilgrims to Mecca; *emir-akhor,* commander of the Turkish horse; *emir-bazar,* overseer of the markets; *emir-alem,* the Turkish standard-bearer; *emir-al Umara,* prince of princes. The title *emir-al-mumenin,* commander of the faithful, was borne by the caliphs. In earlier times the title emir was much more generally assumed by nobles and princes of high rank. It was borne, for instance, by the Thaherids and Samanids in Persia, by the Tulunids in Egypt and by the first seven Ommiads of Cordova, Spain. There were also Christian emirs in the Lebanon region of Palestine, who represented Mohammedan clans converted to Christianity.

Emma, Adelheid Wilhelmine Therese, queen dowager of Holland: b. Arolsen, Germany, 2 Aug. 1858. She was the second daughter of Prince George Victor of Waldeck and Pyrmont, and was married 7 Jan. 1879 to King William III. of Holland. She is the mother of Queen Wilhelmina of Holland, and was Queen Regent of the Netherlands after the death of William III. 23 Nov. 1890 until 6 Sept. 1898, when her daughter ascended the throne.

Emmanuel College, founded in connection with Cambridge University in 1584, by Sir Walter Milday as a Puritan institution. The chapel was designed by Wren. John Harvard, who gave so liberally to education in America, was from this college.

Emmaus, ĕ-mā'us or ĕm'mā-ŭs, Palestine, (1) A village, about eight miles from Jerusalem, the place mentioned in Luke xxiv. 13. The exact location of this village is not known, the modern El Kubebe and also Koloniyeh are mentioned as being the places alluded to in Luke. (2) Modern Amwas, the place mentioned in Macc. iii., iv., and ix. In ancient times and down to the conquest of the Mohammedans, this Emmaus was a place of importance. Its position, about 18 miles northwest of Jerusalem, and near the Roman Road from Jerusalem to Jaffa, on the seacoast, made it prominent.

Emmenagogues, ĕ-mĕn'a-gŏgz, are agents that stimulate the pelvic organs, and are used to bring about a restoration or regulation of the menstrual function if it should be absent or abnormal. Occasionally absence of menstruation is due to anæmia or lack of iron in the blood, in which case taking iron internally, by overcoming the anæmia, restores menstruation and may be thus termed an emmenagogue. More properly speaking, however, the term is applied to such drugs as ergot, quinine, and hydrastis. These bring about direct stimulation of the unstriped muscles of the body, and hence act most forcibly on the uterus, it being the largest mass of unstriped muscular tissue in the body. Aloes, myrrh and the active cathartics act as emmenagogues by increasing the amount of blood in the large intestine and other pelvic organs, thereby increasing the nutrition of the uterus. Occasionally massage and electrical applications are used to bring about the restoration of the menstrual flow, and hence may be included in this group.

Em'meran, or **Emmeram, Saint,** martyr, bishop of Poitiers: b. the last of the 6th century; d. 653. His feast is kept on 22 September, but the exact date and place of his death is not known. In his own day he was renowned for his piety and learning. His biographer says of him: «For his great learning and sanctity he was chosen bishop of Poitiers, in the 7th century; he preached the pure maxims of the gospel with indefatigable zeal, without respect of persons.» After a time his zeal led him to ask permission to go to Bavaria to preach to the «infidels and idolators.» After three years' work in Bavaria, he began a journey to Rome. On the way he was assassinated by men who believed false accusations which a wicked woman had made. He is the patron saint of Ratisbon.

Emmerich, ĕm'mĕr-ĭн, Germany, town in Rhenish Prussia, on the Rhine, five miles northeast of Cleves. It is enclosed by walls and ditches, contains several ancient and modern churches, a gymnasium, ecclesiastical seminary, and orphanage; and has manufactures of woolen and linen cloth, hosiery, leather, etc.; some shipping, and a free port, at which an active trade is carried on, chiefly with Holland. Its history dates from the 7th century. Pop. 11,000.

Emmerson, Henry Robert, Canadian lawyer and politician: b. Maugerville, N. B., 25 Sept. 1853. He was graduated from the Boston University Law School in 1877, was admitted an attorney the same year, and has since been engaged in all the leading cases at Dorchester, N. B. He entered public life in 1888 when he was elected to the Provincial Assembly. He was elected to the Canadian House of Commons in 1891, and is a well-known Free Trader.

Emmet, Robert, Irish patriot: b. Dublin 1778; d. 20 Sept. 1803. He intended to practise law, and with that view studied at Trinity College, Dublin, from which, however, in 1798, he was expelled, on the ground of exciting rebellion. Subsequently he became an object of suspicion to the government, and accordingly quitted Ireland and traveled on the Continent, but returned on the repeal of the suspension of the Habeas Corpus Act. He now became a member of the Society of United Irishmen, whose object was the establishing the independence of Ireland. In July 1803 he was the ringleader in the rebellion in which Lord Kilwarden and several other persons were killed, but which was almost immediately suppressed. Emmet was arrested a few days afterward, tried, and executed by a sentence of the royal commission. His fate excited considerable interest, from the circumstance of his attachment to Miss Sarah Curran, daughter of the celebrated barrister. Moore has immortalized his memory and that of Miss Curran in the poem beginning, «She is far from the land where her young hero sleeps.» Consult: Madden, 'Lives of the United Irishmen.'

Emmet, Rosina. See SHERWOOD, ROSINA.

Emmet, Thomas Addis, American lawyer: b. Cork, Ireland, 24 April 1764; d. New York 14 Nov. 1827. He was a brother of Robert Emmet (q.v.), and being tried for the crime of treason, was sentenced to exile. He came to the United States and became a noted lawyer in New York. In 1812 he was elected attorney-general of the State.

Emmet, Thomas Addis, American gynecologist: b. Charlottesville, Va., 29 May 1828. He was graduated at Jefferson Medical College 1850, and is author of 'Principles and Practice of Gynecology.' He is a celebrated surgeon, and inventor of several special surgical instruments and operations.

Em'metsburg, Iowa, city, county-seat of Palo Alto County; on the Des Moines River, the Burlington & M.; the Chicago, M. & St. P., and the Cedar Rapids R.R.'s.; about 123 miles northeast of Sioux City. It is in an agricultural section of the State, and it has several grain elevators. Some of the industries are the manufacturing of butter, cheese, and flour. Pop. 2,468.

Emmett, Daniel Decatur, American song writer and negro minstrel: b. Mount Vernon, Ohio, 1815. He served in the army, joined a circus company 1835, and formed the first negro minstrel company 1842 with Frank Brown, William Whiltock, and Richard Pelham, appearing at the old Chatham Theatre, New York, and later in Boston, and in England, where Emmett remained till 1844. He was with Dan Bryant 1854–65, writing the famous song 'Dixie' in 1859. He became a manager 1865, returning to his native town 1878. He was a most prolific song writer, and among his productions were: 'Old Dan Tucker'; 'The Road to Richmond;' and 'The Boatman's Dance.'

Em'mitsburg, Md., town in Frederick County; on a branch of the Western Maryland R.R.; about 45 miles northwest of Baltimore. The town is known chiefly for its two large educational institutions, Mount St. Mary's Theological Seminary (q.v.), just outside the town's limits, and St. Joseph's Academy, within the town. It contains also the Mother-house and Seminary of the Sisters of Charity of St. Vincent de Paul, from Paris. Emmitsburg was the scene of the labors of Mother Eliza Seton (q.v.) when establishing the Sisters of Charity in the United States. There are about 1,800 sisters working in different parts of the country, who belong to this Mother-house. Pop., including sisters whose homes are here, 2,074.

Emmons, Ebenezer, American geologist: b. Middlefield, Mass., 1799; d. 1863. He was educated and afterward taught at Williams College, later becoming geologist-in-chief, second district, New York State Geological Survey. He introduced the new Taconic stratigraphic system, not now in vogue. He was made professor of chemistry in the medical college at Albany 1838, and had charge of the geological survey of North Carolina 1858. His works include: 'Manual of Mineralogy and Geology' (1826); and 'American Geology' (1856).

Emmons, George Foster, American naval officer: b. Clarendon, Vt., 23 Aug. 1811; d. Princeton, N. J., 2 July 1884. He entered the navy as midshipman in 1828; was promoted lieutenant in 1841; rear-admiral 1872; and was retired the next year. He was a member of the South Sea exploring expedition under Capt. Wilkes in 1838–42; took part in the Mexican war; and during the Civil War captured Cedar Keys, Fla., and Pass Christian, Miss., with 20 prizes in 1862. He served as captain of the fleet under Dahlgren, off Charleston, in 1863; and raised the American flag over Alaska in 1868.

Emmons, Nathaniel, American Congregational clergyman: b. East Haddam, Conn., 20 April 1745; d. Franklin, Mass., 23 Sept. 1840. After graduating from Yale College 1867 he was ordained pastor of the Congregational Church in Franklin, Mass., which pastorate he held for 54 years, being one of the originators of the Massachusetts Missionary Society and an editor of the magazine from which afterward sprang the 'Missionary Herald.' He was a strong pamphleteer, a Federalist, and an opponent of slavery. His 'Collected Works' were printed, with a memoir, by his son-in-law, Jacob Ide (1842).

Emmons, Samuel Franklin, American geologist: b. Boston, Mass., 29 March 1841. He was graduated at Harvard, taking post-graduate courses at the Ecole Imperiale des Mines, Paris, and Freiberg, Saxony, Mining School, and is a member of several scientific societies, including the National Academy of Sciences, and the Geological Society of America, of which he became president 1896. He has been in the employ of the government almost uninterruptedly since 1867 and geologist upon the United States Geological Survey, Colorado division, since 1879. Among his writings are: 'Descriptive Geology of the Fortieth Parallel Region' (1877); 'Statistics and Technology of the Precious Metals' (1885); 'Geology and Mining Industry of Leadville, Colorado' (1886); 'Geology of Lower California' (1890); 'Geological Distribution of the Useful Metals in the United States' (1893); 'Progress of the Precious Metal Industry of the United States' (1893); 'Geology of the Denver Basin in Colorado' (1896).

Em'odin, one of the active constituents in *Cascara sagrada* and in other species of the genus *Rhamnus*. Emodin acts as a cathartic.

Emory, John, American Methodist bishop: b. Spaniard's Neck, Queen Anne County, Md., 11 April 1789; d. Reisterstown, Md., 16 Dec. 1835. He was graduated at Washington College 1804, practised law, and in 1810 entered the Methodist ministry, becoming a bishop in 1832. He published: 'The Divinity of Christ Vindicated'; 'Defense of Our Fathers,' etc.

Emory, Robert, American educator: b. Philadelphia, Pa., 29 July 1814; d. Baltimore, Md., May 1848. He was a son of John Emory (q.v.). He was appointed professor of ancient languages in Dickinson College in 1834; resigned in 1839; and entered the Baltimore Annual Conference of the Methodist Episcopal Church. He was recalled to the college and made president pro tem. in 1842, and president from the retirement of Dr. Durbin till his death. His publications include: 'Life of Bishop Emory' (1841); 'History of the Discipline of the Methodist Episcopal Church' (1843); and 'Analysis of Butler's Analogy.'

Emory, William Hemsley, American military officer: b. Queen Anne County, Md., 9 Sept. 1811; d. Washington, D. C., 1 Dec. 1887. He was graduated at the United States Military Academy 1831; served in the Mexican war and was chief astronomer for the survey of the boundary between the United States and Mexico in 1848–53. He was appointed lieutenant-colonel of cavalry in 1861; served in the Federal army during the Civil War, and after the War was in command of the Department of Washington till 1876, when he was retired with the rank of brigadier-general United States army. Gen. Emory was author of several important works, including: 'Notes of a Military Reconnoissance in Missouri and California'; and 'Report of the United States Boundary Commission.'

Emory College, an educational institution in Oxford, Ga., founded in 1836 under the auspices of the Methodist Episcopal Church; reported at the close of 1900: Professors and instructors 14; students 289; volumes in the library 20,000.

Emotion, a term applied to a complex series of reactions that have distinct representations in consciousness; or, as defined by Baldwin, emotion "is a total state of consciousness considered as involving a distinctive feeling-tone and a characteristic trend aroused by a certain situation which is either perceived or ideally represented." The conception of the word emotion is of comparatively modern date, but there is no doubt that the nature of emotions is one of the oldest of old psychological problems. Emotions imply peculiar vividness of feeling which is not associated with known and palpable external sources of stimuli. As to their exact character, it is very readily understood that we can know nothing whatever of them, but they may be thought of from at least two different standpoints. By many of the older psychologists and metaphysicians emotions have been considered as arising from the inner consciousness, whereas at the present time there is a large school of psychologists who have accepted what is known as the James-Lange theory of emotions. By this theory is meant, in general terms, that the feeling-tone has its origin in organic or visceral sensations, and that the representations in consciousness of these sensations, in general, constitutes the emotion. Thus the theory would posit as a corollary a certain quantity and quality of external stimuli. As a concrete example, if one in a general way attempts to analyze one's emotions following the hearing of a highly emotional opera, such as one of Wagner's compositions, the origin of the emotional state induced would be construed as due to the mental representations of the motor activities, as seen and as heard. Thus unconsciously the spectator sings and acts cerebrally and a tenseness of the vocal cords and of the whole muscular apparatus of the body results from the imitative effort to make the necessary sounds and to reproduce the necessary movements. This largely constitutes the feeling-tone, which is interpreted as emotion. So with the emotion of fear: the protoplasmic contractions of the various organs of the body acted upon by visual or auditory stimuli give the feeling-tone of fear. The sound of the cracking of a stick in the deep forest when one is alone causes an involuntary contracting process of the blood-vessels throughout the entire body; perhaps also of other organs; and it thus induces the feeling-tone of fear. This theory may be applied to a large number of emotional states, all of which may be analyzed along similar lines from the strictly biological point of view of emotion. It will probably take much more searching and definite knowledge of the action of the sympathetic nervous system before all of the various phenomena connected with the feeling-tone can be satisfactorily explained along the lines of the James-Lange theory. There seems, however, to be little doubt, in the minds of many, that the complete interpretation of emotion lies along some such line of research. Consult: James, 'Principles of Psychology'; Lange, 'Ueber Gemüthsbewegungen' (1887); Baldwin, 'Dictionary of Philosophy and Psychology,' Vol. I. (1901); Spiller, 'The Mind of Man' (1903); Stout, 'Principles of Psychology' (1900).

Empalement, a mode of executing criminals, mentioned by Juvenal, often inflicted in Rome, and still used in Turkey and Arabia. In England the dead bodies of murderers were sometimes staked in this manner, previous to being buried; but the custom was abolished in 1823.

Empáran, Diego de, dē-ā'gō dā ĕm-pä'rän, Mexican writer: b. Puebla, 5 April 1718; d. Ravenna, Italy, about 1807. His book, 'The Jesuits and the Pope' (1746), published soon after entering the priesthood, gained him five years' imprisonment. The year after his release he issued a bitter criticism of Church dignitaries, for which he was deposed from the priesthood and imprisoned in the Castle of Sant' Angelo, but released later. His work was burned by the executioner. His other works include: 'The Tombs of Mohammed and Christ'; 'Voltaire and His School'; 'Science and Superstition'; and 'Religion and Hygiene.'

Empecinado, Don Juan Martin Diazel, dōn hoo-än' mär'tēn dē'äth äl ĕm-pā-thē-nä'dō, Spanish patriot: b. Cestrillo de Duoso, Valladolid, 1775; d. 1825. He joined the army at 17, and for his activity in the war against the French in the peninsula was appointed colonel and later made a field marshal. Losing favor with King Ferdinand VII. on account of his action in petitioning him to restore the Cortes, he was thrown into prison, his imprisonment being followed by banishment to Valladolid. Taking part in the insurrection 1820 he saw much fighting, but was captured 1823, cruelly treated while a prisoner and after two years he was stabbed while resisting the executioners by whom he was about to be hanged.

Emped'ocles, Greek philosopher: b. Agrigentum, Sicily, about 460 B.C. His fellow-citizens esteemed him so highly that they wished to make him king; but being an enemy to all political forms which elevate a few above their fellows, he refused their offer, and prevailed on them to abolish aristocracy, and introduce a democratical form of government. Aristotle states that he died in obscurity at the age of 60 years, in the Peloponnesus, but there are various legends respecting the manner and place of his death. Empedocles presented his philosophy in a poetical form. His general point of view is determined by the influence of the Eleatic school upon the physical theories of the Ionic philosophers. He assumed four primitive independent substances — air, water, fire, and earth, which he designates often by the mythical names Zeus, Hera, etc. These four elements, as they were called, kept their place till modern chemistry dislodged them. Along with material elements he affirmed the existence of two moving and operating powers, love and hate, or affinity and antipathy, the first as the uniting principle, the second as the separating. The contrast between matter and power, or force, is thus brought out more strongly by Empedocles than by previous philosophers. His theory of the universe seems to assume a gradual development of the perfect out of the imperfect, and a periodical return of things to the elemental state, in order to be again separated, and a new world of phenomena formed. Of his opinions on special phenomena may be mentioned his doctrine of emanations, by which, in connection with the maxim that like is known only by like, he thought to explain the nature of perception by the senses. He attempted to give a moral application to the old doctrine of the transmigration of souls, his views of which resembled those of Pythagoras. The fragments of Empedocles have been edited by Sturz (1805); Karsten (1838); and Stein (1852). Consult monographs by Lommatsch (1830); Raynaud (1848); and Gladisch (1858).

Emperor, the title of the highest rank of sovereigns. The word *imperator*, from *imperare*, to command, had very different meanings among the Romans at different periods. It signified one who exercised *imperium*, authority, whether in a civil or military capacity. In the time of the republic consuls were called *imperatores* before they entered on their office. The soldiers afterward conferred the title on their general, after a victory, by hailing him *imperator;* the senate also called a victorious general *imperator* until he had celebrated his triumph. After the overthrow of the republic *imperator* became the title of the rulers or emperors who assumed to themselves personally every department and privilege of civil and military *imperium*. Victorious generals were still, however, sometimes saluted with the title *imperator*, in its original sense. With the fall of Rome the title was lost in the West, but was kept up in the Eastern or Byzantine empire for nearly 10 centuries. In 800 it was renewed in the West when Charlemagne was crowned, by Leo III., as "Carolus Augustus, the God-sent and pious emperor of Rome," which title was borne by his successors until the dissolution of the Holy Roman empire in 1806.

The Eastern empire having been finally overthrown by the conquest of Constantinople in 1453, the imperial dignity in the East became extinct. The sultans, who succeeded the emperors, have never received, in official language, the title of emperor. This title was adopted in Russia by Peter I. in 1721, but the right of the Russian sovereign to its possession was not acknowledged by the German empire until 1747, by France in 1745, and by Spain 1759. Napoleon adopted the old idea of an empire, as a general union of states under the protection, or at least political preponderance, of one powerful state. Napoleon crowned himself as emperor in 1804; the title fell into disuse at his deposition in 1815, but was revived by his nephew in 1852, with whom it again ended on 5 Sept. 1870. In 1806 the first German empire, 1,000 years old, became extinct, and the German emperor, Francis II., adopted the title of Francis I., emperor of Austria. In December 1870 the second German empire was formed, King William of Prussia having accepted the imperial office and title offered him at Versailles while engaged in the siege of Paris.

Great Britain is considered as an empire, the crown as imperial, and the Parliament is styled the Imperial Parliament of Great Britain and Ireland; but the sovereign has not the imperial title in reference to the home dominions, though the king bears the title of emperor of India. The sovereigns of China, Japan, and Morocco are often, though with little propriety, called emperors.

Emperor, or **Purple Emperor,** name of a butterfly of the genus *Apatura*. The antennæ are rather long, the ground color of the wings is rusty black, decorated in the male with a purple lustre wanting in the female; seven white spots in the male; as many faint yellow ones in the female; on the four wings above a transverse white band; an oscellated spot and a darker marginal bar on the hinder ones.

Emphysema, ĕm-fĭ-sē'ma, a disease of the lungs, in which there is a dilatation of the air vesicles with lack of elastic recoil. It is most frequently the result of persistent high intra-alveolar tension, acting upon weak lung tissue. The most important symptoms are bronchitis, loss of breath with harsh and wheezy respirations, and a certain amount of cyanosis or blueness of the face, due to insufficient oxidation in the lungs.

Emphyteusis, em-fĭ-tū'sis (Gr. "implanting"), in Roman law, a perpetual right in a piece of land, for which a yearly sum was paid to the proprietor. It was secured by contract on condition of improvement, as well as payment of rent, and much resembled a feudal holding in the features of perpetuity, etc. See FEUDAL SYSTEM.

Empire City, a name given to the city of New York. See EMPIRE STATE.

Empire State, a name given to New York State because of its predominant wealth and commerce.

Empirical School. See EMPIRICISM.

Empiricism (from Greek ἐμπειρία, experience, trial), the philosophical doctrine which regards immediate sense experience as the only source of knowledge and as furnishing the only practical rules of conduct. It is thus fundamentally opposed to the doctrine of innate ideas, and to all *a priori* theories of the *origin* of knowledge. And, on the other hand, as a *method* of knowledge it is opposed to Rationalism (q.v.), which proceeds to reason out deductively the necessary consequences of certain conceptions and principles that are taken as self-evident. As a theory of the *origin* of knowledge, empiricism teaches that all truth is based on sensation. The mind is originally a *tabula rasa*, an empty chamber, which gets its filling from the impressions coming to it through sensation, inner and outer. It thus minimizes, or altogether denies, all original activity on the part of the mind, and tends to explain all mental complexes and constructions as the resultants of the mechanical play of the elements themselves. The doctrine thus logically leads to sensationalism, and this, through its subjective and relativistic character, to scepticism. This development has more than once been illustrated in the history of philosophy. We may trace it in the ancient world among the sophists, though here the principle is not so consciously maintained, or so systematically worked out as in modern thought. Locke is usually regarded as the father of modern Empiricism. His most important successors who have further developed the doctrine are Berkeley, Hume, Hartley, James Mill, and John Stuart Mill, in England, and Condillac, Bonnet, and Helvétius in France. Kant, by his method of criticism, and Herbert Spencer, through the conception of evolution, have sought in different ways to reconcile Empiricism with the *a priori* standpoint of Rationalism.

JAMES E. CREIGHTON,
Professor of Philosophy, Cornell University.

Empiricism, in medicine, refers to at least two different things. In the age of renovation, or the reform period in medicine, a special group of men, Phalinus and Serapis at their head, founded what was called the Empirical School. They were disciples of Herophilus and Erasistratus, and from 200 to 300 A.D., they formed one of the most important Alexandrian schools. Their followers were mostly opposed to the teachings of the Dogmatic School. Their chief point of view was that of practical observation, as opposed to the theoretical speculations of the Dogmatic School. Their chief alliances were with the skeptics. Anatomy, insomuch as it could teach nothing of physiology, they believed was of secondary importance.

At the present day what is meant by empiricism is the following of accumulated experience independent of rational explanation. A physician uses a drug empirically because he, or others, believe it to be of service, although no reason can be given by him, nor by others, why it should be of service. Little by little, the real causes of the action of drugs that physicians have used from time immemorial has been revealed by students of medicine, and the reproach that medicine is an empirical science has little weight at the present time.

Employer's Liability, the relation of the hirer to the hired, as party in a contract. The hire of services is a contract, by which the work or service of a person is given for a compensation or reward. Out of the contract arises the relation of master and servant, or that of employer and employee. The rule of law is well established, that an implied contract cannot arise, where there is a subsisting express contract, covering the entire subject matter. A contract of hiring, unless for more than one year, need not be in writing. And as between strangers the general rule is, where nothing appears to the contrary, that whenever services are rendered and received, a contract of hiring, or an obligation to pay, will be implied. A contract to do an act that is immoral is void at common law and will not be enforced. Contracts which involve the doing of acts contrary to public policy, are also void and cannot be enforced. One who offers himself for employment in a professional capacity represents himself by implication as possessing: (1) That reasonable degree of learning and skill, which is usually possessed by the professors of the same art or science, and which is ordinarily regarded by the community, and by those conversant with the employment, as necessary to qualify him to engage in such business. (2) That he will use reasonable and ordinary care and diligence in the exercise of his skill and the application of his knowledge, to accomplish the purpose for which he is employed. (3) That he will use his best judgment in the exertion of his skill and the application of his diligence. The skill required is not that of the highest or of the lowest member of his profession, but such as averages with the knowledge and skill usually possessed by a majority of the profession. The fact, however, that a professional man has requested and received no pay for his services, does not exempt him from liability for injuries or damages resulting from his failure to exercise the ordinary care and skill of his profession, but the patient or client must obey the instructions of the surgeon, physician, lawyer, etc. The hiring of artistic and scientific services is governed by the same general principles of law that are applicable to contracts of hire of other services. The law implies a contract on the part of the employee, or person hired, that he will perform the service skilfully, and he will be liable for damages to his employer for a failure to do so. Where mechanical services upon a chattel are the subject of hire, and the chattel is entrusted to the workman, he becomes a bailee of the property to be worked upon, and is liable for ordinary neglect. The relation of the workman to the employer is personal, and grows out of the confidence the employer is presumed to repose in the skill and fidelity of his employee when entrusting his property to him for the service intended to be performed on or toward it. And the law implies a contract on the part of the employee or bailee to perform the service skilfully, and then return the property faithfully on payment for his service. The employee is liable for his negligence or misconduct, whether the damage is done directly to the property of the employer or whether it arises from the reparation which the employer has been compelled to make to third persons to satisfy his liability for the acts of his employee.

The recent disputes between industrial corporations and their employees, frequently leading to strikes which are productive of serious inconvenience and pecuniary loss to the general public, have prompted several States to interfere by legislation in order to control the contract-making power of the employer and the employed. Boycotting unpopular employers or employees, in order to influence the making of contracts, is expressly prohibited by certain States, while, in many more, such a prohibition seems implied by the terms of recent statutes. Fourteen States prohibit the employer from exacting an agreement from any one, as a condition of being employed, that he will not join or become a member of any labor organization. Blacklisting, by which employees are cut off from the opportunity of making a contract and gaining employment is expressly declared unlawful in 21 States, and in eight other States its illegality is implied in recent statutory enactments. The option of the employer to exact by contract more than eight hours' work is taken away by the laws of a majority of the States, and in very many of them eight hours is made to constitute a day's work on public roads, highways and bridges, in State, county and municipal undertakings. This specific legislative interference in the dealings of the employer and the employed has been supplemented by the institution of a permanent board to settle labor disputes, in which the public, organized labor and the employers are represented by delegates.

Employment Bureaus, establishments, whether private or public, at which those seeking employment are put into communication with those who are offering it. Private employment bureaus are found in every large city, but they are often conducted without judgment, sometimes have been accused of dishonesty; they are in any case mercenary, and their usefulness is at least problematical. Public bureaus, opened by the national or city government, are non-mercenary, and the motive that has prompted their establishment is a sound humanitarian and political motive. Such bureaus have two practical objects. They are a means of communication between employer and employee, labor exchange, as they are called in France. In the second place they do something toward settling the wage question, by giving quotations of the amount offered and asked.

The public governmental employment bureau originated in France. In 1848 one such bureau was established in each of the mairies of Paris. The institution languished, but in 1886 was revived and has since become universal in France. The first employment bureau opened in England was at Egham, near London, in 1885, and the movement has since been spreading to the larger towns. Switzerland followed suit with a labor bureau at Berne in 1888, and another at Basle in 1889; Germany established one at Freiburg in 1892, and the movement has been taken up enthusiastically by almost every city of importance. The United States has its government employment bureaus also, and Ohio was the pioneer in the movement. Nine States have authorized their establishment by legislative enactment, and although three States have tried and given up the government employment bureau, they are States of the West, where employment is plentiful, and the need of an intermediary is scarcely felt, certainly not as keenly as in the crowded cities of the East.

Emporia, Kansas, city and county-seat of Lyon County; on the Neosho River near its junction with the Cottonwood, in the central part of the State, and on the Missouri, K. & T., and a division point of the Atchison, T. & S. F. and the Kansas City, M. & O. Railways; 60 miles southwest of Topeka. It is the commercial centre for a large section of country devoted to farming and dairying and to the fattening of western range cattle for the eastern market. Emporia has a thriving jobbing and export trade and some manufactures, including marble and iron works, carriage and canning factories, woolen mills, and flour and grist mills. It has three banks, with a combined capital of $250,000 and doing a large annual business, and daily and weekly newspapers. Gas is served by a private company, and the water-works and electric-lighting plant are owned and operated by the city. Emporia is the seat of the State Normal School (2,000 students), and of the College of Emporia (Presbyterian), and the Western Conservatory of Music, and has a business college, railroad and public libraries, nine school buildings, 11 churches, and many handsome business buildings and private residences. It is the largest town in Kansas that never has permitted a saloon to open within its limits since the passage of the prohibitory law in 1880. The city is governed by a mayor, elected biennially, and by a council, half of which is elected each year. Emporia was founded in 1856 by P. B. Plumb, afterward United States Senator, and a group of pioneers from the Middle States; it was incorporated in 1870. Pop. (1904 est.) 9,000.

WILLIAM ALLEN WHITE,
Editor 'Emporia Gazette.'

Empyema, ĕm-pĭ-ē'ma, a collection of pus consequent on pleurisy. True empyema is pus secreted from the pleura; the false, when an abscess of the lung bursts into the cavity of the chest. When the quantity of fluid is so large as to cause great dyspnœa and endanger life, it must be let out by tapping the chest.

Empyre'an, a word used by the ancient Greek philosophers to designate the highest region of the heavens, where the purest and most rarefied elements of fire and light exist; and by mediæval poets to indicate the ninth heaven, the home of the blessed. In modern poetry the empyrean is merely the over-arching dome of the heavens.

Empyreuma, ĕm-pĭ-roo'ma (Gr. «a live coal covered with ashes to keep the fire in it»), the smell acquired by organic matter when subjected to the action of fire, but not enough to carbonize it entirely. The products of imperfect combustion, as from wood heated in heaps or distilled in close vessels, are frequently distinguished as empyreumatic.

Ems, ĕmz, Germany, a celebrated watering place in the Prussian province of Hesse-Nassau; on the river Lahn. The environs are beautiful. As early as 1583 it was a town of resort as a watering-place. The mineral waters at Ems are warm — from 70° to 133° F.; they are of the saline class, containing large quantities of carbonic acid gas, and are used with much effect in chronic catarrhs, pulmonary complaints, and some other diseases. The history of the town dates back to the 9th century, and the lead and silver mines have been worked a number of years. Since 1865 the fame of the springs has overshadowed its industrial and trade advantages. It was here that the memorable interview between the king of Prussia and the French ambassador, Benedetti, took place which formed the prologue to the Franco-Prussian war of 1870–1. Pop. 6,519.

Ems, a river of Germany, which rises at the southeast extremity of the Teutoburger-Wald, in Lippe-Detmold, flows northwest through Rhenish-Prussia, and Hanover, and into the Dollart, near Emden; length 234 miles. It is navigable as far as Papenburg for light vessels. In 1818 it was connected by a canal with the Lippe, and thus with the Rhine, and its importance has been greatly increased by the opening of the Dortmund-Ems and other canals.

Emser, ĕm'zĕr, **Hieronymus,** German Roman Catholic theologian: b. Ulm 26 March 1472; d. Dresden 8 Nov. 1527. In 1502 he became professor at the University of Erfurt, where Luther is said by him to have been among his pupils. In 1504 he established himself at Leipsic, where he also lectured at the university. With Luther and the theologians of Wittenberg generally he was on good terms until the disputation of Leipsic in 1519, from which time he made, in union with Dr. Eck, incessant endeavors to oppose the increasing influence of Luther and the progress of Protestantism. The German translation of the Bible by Luther was attacked by him as erroneous, whereupon it was forbidden in Saxony by Duke George. Emser then himself published a translation of the New Testament into German, made from the Vulgate (1527). He also wrote: 'Vita S. Bennonis,' as he ascribed to St. Benno his recovery from a severe sickness.

E'mu, the only representative of the family *Dromaiidæ,* and with the cassowaries the Australian representatives of the order *Struthiones.* In size the emu ranks between the African ostrich and the rhea of South America, the African bird being seven feet in height and the emu five. In general appearance and form it is more bird-like than either of the others. Like the cassowary of northern Australia, its head and neck are feathered, and the back is gracefully arched. Its body is covered with a rich brownish plumage. With the rhea and cassowary, it has three toes on the foot, while the African ostrich has but two. The emu is a bird of the plains, where it feeds upon fruits, herbs, and roots. The nest is scooped in the sand, and the number of eggs is six or seven, of an attractive green, each measuring five inches in length. The feathers have no ornamental value, and the flesh is eaten only by the natives. Coursing the emu has been carried to such an extent that the birds of New Holland, once spread throughout the whole continent, are now in many parts exterminated. The emu utters a faint booming noise. In confinement it is found to be tractable, and is readily tamed.

Emul'sin, an active enzyme found in many seeds and especially in the bitter almond, but also in the sweet almond and the cherry: The addition of a small amount of water to this seed develops the characteristic reaction and the formation of the oil of bitter almonds, containing the deadly poison prussic acid in solution.

Emul'sion, the term applied to those preparations in pharmacy in which oleaginous substances are suspended in water by means of gum, sugar, carrageen, yolk of egg, etc. In general it will be found that the bulk of the emulsifier must first be taken, while the oil should only be added little by little, rubbing together in a mortar, and taking care that it is completely absorbed or emulsified before further additions. Should too much be added, the effect is to throw out most of what has already been incorporated; it is then almost impossible to remedy the error. The emulsion of cod-liver oil is familiarly known.

Emys, ĕm'ĭs, a member of the family *Emydidæ,* which includes all the fresh-water turtles, and is the largest group in the order. It varies from the prevailing type of the order in having a convex rather than a depressed shell, which is also rounded like that of the box-tortoise. Its color is dark green, spotted with yellow. The carapax is provided with lids, which are closed down at will when the feet are drawn in. *Emys meleagris,* known as Blanding's box-tortoise, is larger than the common box-tortoise. It is the only representative of the genus in North America, and is found east of the Mississippi River.

Enaliosauria, ĕ-năl'ĭ-ō-sâ'rĭ-a, a name proposed by Conybeare, and no longer in use, for the fossil reptiles, Ichthyosauri and Plesiosauri

EMU (*Hippalectryo Uniappendiculatus*)

(Ichthyopterygia and Sauropterygia, of Owen, respectively), which are now known to differ too widely to be thus combined.

Enambuc, or **Esnambuc, Pierre Vandrosque Diel d',** pē-ār vän-drōsk dē-ĕl dā-nōn-bük, French navigator: b. Dieppe about 1570; d. St. Christopher, W. I., December 1636. Being of an adventurous spirit, he sailed from Dieppe in 1625 in a brigantine of eight guns, for the Antilles. He landed in the island of St. Christopher on the same day with a party of English colonists, with whom he divided the island, and, until his death, held the French half of the colony with extraordinary tenacity. In 1635 he took possession of Martinique, in the name of the king of France, and founded the town of St. Pierre.

Enamel, the name given to vitrified substances of various composition applied to the surface of metals. Enameling is practised (1) for purposes of utility, as in making the dial-plates of watches and clocks, coating the insides of culinary vessels, etc., when it may be considered as belonging to the useful arts; and (2) for producing objects of ornament and beauty — artistic designs, figures, portraits, etc.— when it belongs to the fine arts. The basis of all enamels is an easily fusible colorless silicate or glass, to which the desired color and the desired degree of opaqueness are imparted by mixtures of metallic oxides. The molten mass, after cooling, is reduced to a fine powder, washed, and the moist paste is then usually spread with a spatula on the surface of the metal; the whole is then exposed in a furnace ("fired") till the enamel is melted, when it adheres firmly to the metal. The metal most commonly used as a ground for enamel is copper; but for the finest kinds of enamel work gold and silver are also used.

Artistic or Ornamental Enameling.— This art is of great antiquity. It was extensively practised at Byzantium from the 4th till the 11th century, and afterward in Italy, in the Rhenish provinces, and at Limoges in the south of France. The Byzantine and other early styles of enamel work, down to the 14th century, were generally employed in ornamenting objects connected with the service of the Church. Enamel was also greatly used in ornamenting jewelry, and vessels made for use or display in the mansions of the rich, such as salt-cellars, coffers, ewers, candlesticks, etc.

Manner of Execution.— Enamel-work may be divided into four kinds: (1) *Cloisonné* (q.v.), or inclosed, in which the design is formed in a kind of metal case, generally of gold or copper, and the several colors are separated by very delicate filigree gold bands, to prevent them running into one another. Of this style the grandest example extant is the famous Pala d'oro in Saint Mark's church, Venice. (2) *Champ Levé,* practised by the Rhenish and early Limoges schools. In this process the ornamental design, or the figures which were to be filled in with color, were cut in the metal (generally copper) to some depth; wherever two colors met, a thin partition of the metal was left to prevent the colors running into each other by fusion when fired. (3) *Translucent* enamel, which had its origin in Italy, was composed of transparent enamel of every variety of color, laid in thin coatings over the design, which was incised on the metal, generally silver, the figure or figures being slightly raised in low relief, and marked with the graver, so as to allow the drawing of the contours to be seen through the ground, instead of being formed by the coarse lines of the copper, as in the early Limoges enamels. (4) *Surface-painted* enamels, which may be divided into two stages. The first stage, which is known as the late Limoges style, sprang up about 1475, and flourished till 1630. In this the practice was to cover the metal plate with a coating of dark enamel for shadows, and to paint on this with white, sometimes having the hands and other parts of the figures naturally colored. In this method the plate is covered with a white opaque enamel, and the colors are laid on this with a hair-pencil, and fixed by firing. The paints are prepared by grinding up colored enamels with oil of spike and, when fused by the heat, they become incorporated with the enamel of the ground.

The greater part of the artistic enamel-work of the present day is Japanese and consists of cloisonné work on a copper basis.

Enameled Iron.— Since the beginning of the 19th century many attempts have been made to cover iron with a vitreous surface; several patents have been taken for such methods of enameling. The chief difficulty in applying enamels to iron arises from the tendency of the metal to oxidize before it reaches the temperature at which the enamel fuses, and to become brittle from the oxide combining with the silica of the enamel. This action being superficial, the mischief is the greater in proportion to the thinness of the iron. Therefore it is much easier to enamel thick cast-iron vessels than thin vessels made of sheet-iron. A glass may be made by combining either silicic acid or boracic acid with a base; the latter fuses at a lower temperature than the former, but the glass is much dearer and not so durable as the silica glass. The enamels used for coating iron consist of a mixture of silica and borax, with various basic substances, such as soda, oxide of tin, alumina, oxide of lead, etc. Lead is not, or ought not to be, used in the enamel for coating culinary vessels. A great variety of articles, many of them beautifully decorated in colors, such as grate-fronts, clock-dials, panels of different kinds, sign boards, tablets, and name plates, are now executed in enameled iron at a moderate cost. It is also applied to corrugated roofing. The effect of heat on enameled iron, especially, is to expand the metal more than the enamel and cause the latter to peel off. Acids find their way through minute invisible pores which exist in the best enamel; when once they reach the iron, they rapidly spread between it and the enamel, and undermine and strip it off.

The enamel of teeth is the very hard translucent white layer covering the working surfaces of the dentine, or ivory of the teeth.

Luis Palma di Cesnola,
Late Director Metropolitan Museum of Art.

Enargite, en-är'jīt, a native sulpharsenate of copper, of which it contains 48.3 per cent. It constitutes an important ore of copper at Butte, Mont., occurring there and elsewhere in cleavable-granular masses, also in orthorhombic prisms. It has eminent prismatic cleavage, a brilliant metallic lustre, and grayish-black color and streak. Its hardness is 3 and specific gravity 4.44.

Enara, ā-nä'rä, or **Enare**, ā-nä'rä, a lake in Finland; area, about 145 square miles. The outlet is Patsjoki River, which flows into the Arctic Ocean. A town of the same name, at the southwest extremity, is inhabited chiefly by fishermen.

Enarea, ĕ-nä'rā-ä, a country of the Gallas, south from Abyssinia, between lat. 7° and 8° N.; and lon. 35° and 37° E. In the valley of the Gibbi, immediately beyond Sakha, the chief town of the country, are extensive plantations of coffee, which, along with ivory, is largely exported. The inhabitants are the most civilized of the Gallas, and show much skill in manufactures.

Enault, Louis, loo-ē ā-nō, French novelist: b. Isigny, Calvados, 1824; d. Paris 1900. He used the pen-name "Louis Vermond." He wrote many novels and books of travel, including among them: 'Promenade en Belgique et sur les bords du Rhin' (1852); 'La Terre Sainte' (1854); 'Constantinople et la Turquie' (1855); 'Voyage en Paponie et en Norvège' (1857); 'La Méditerranée, ses iles et ses bords' (1862); 'L'Amerique centrale et meridionale' (1866); 'Paris brûlé par la Commune' (1871); 'Valneige' (1887); 'Le Château des Anges' (1891); 'Tragiques Amours' (1891); 'Jours d'Epreuve' (1894); 'La Tresse bleue' (1896); 'Myrto' (1898); and a French translation of 'Uncle Tom's Cabin.'

Encænia, ĕn-sē'nĭ-a, or **Encenia**, a name given to the feast in commemoration of the dedication or consecration of Christian churches. In early times it was applied to the feast in honor of the founding of a city as well as in honor of the founding, or taking possession by dedication or consecration, of churches. The custom of observing the anniversary of the consecration of a church or cathedral dates from the time of Constantine, when Christians were permitted more freedom of worship in the Roman territory; but the Jews before the coming of Christ solemnly dedicated their tabernacles; and in a certain sense, consecrated their houses of worship. The name is applied also to commemorative festivals in honor of the founders and benefactors of Oxford and Cambridge universities. At Oxford University "Commemoration," or "Encænia," usually takes place the third Wednesday after Trinity Sunday. The oration in honor of the founders and benefactors is given in Latin.

Encalada, Manuel Blanco, mä-noo-ĕl blän-kō ān-sä-lä'dä, Chilean soldier and statesman: b. Buenos Ayres, Argentina, 1790; d. Santiago, Chile, 5 Sept. 1876. He studied at Madrid, and in the Naval Academy at Leon, and after deserting from the Spanish ranks, joined the Chilean revolutionary party, and served with distinction both in the artillery and in the navy. He became rear-admiral in 1819, and major-general of infantry in 1820; and in 1825 was appointed head of the army of Chile. He was for two months president of the republic in 1826, governor of Valparaiso 1847–52, and minister to France 1853–8.

Encaustic Painting (Lat. *encaustica*, Gr. ἐγκαυστική, "burning in"), an ancient method of painting, the final process of which consisted in the application of fire to the surface of the picture. The vehicle used was wax stiffened by an admixture of resin, and the colors were softened by heating, and then laid on with a brush. Both the inside and outside walls of a building were thus decorated, and sculptures in marble thus colored, and it is considered by some that neither oil, tempera, nor fresco paintings are so permanent as those executed by this now obsolete process. No important examples of classic Greek encaustic painting have come down to us; such as those of Polygnotus, whose 'Battle of Marathon' in the Stoa Poikile, or Painted Porch, at Athens, retained its colors unimpaired for 900 years. Perhaps the most interesting remains of the kind are the Egyptian paintings discovered at the Oasis of Fayum. They were brought to light in 1887, are on sycamore wood, and are of high artistic as well as historic value. They consist of bust portraits, sometimes sufficiently extended as to display the hands. They have been distributed among the museums of Europe. While evidently belonging to the later Roman empire, in time, they must have been produced under Greek inspiration. Encaustic painting is one of the lost arts, and the details of its production only to be guessed at. Consult, however, Cros et Henry, 'L'encaustique et les autres procédés de peinture chez les anciens' (1884), and Ebers, 'Die hellenischen Bildnisse aus dem Fajjûm, untersucht und gewürdigt' (1893).

Encaustic Tiles, a species of ornamental tiles made of a finer kind of clay than the ordinary tiles, but not so fine as porcelain. These are of two sorts: plain and figured. The plain tiles are sometimes square, but more frequently triangular, and of different colors; the latter shape renders possible a greater number of designs when the tiles are employed in a sort of mosaic work for the paving of churches, halls, etc. They are made by putting the colored clay into strong steel molds and subjecting it to a pressure of several hundred tons, by means of a plunger fitting accurately into the mold. The under surface of the tile is usually ribbed in order to afford a better hold for mortar. The clay for figured tiles is pressed into an iron mold, the bottom of which is formed of a plaster of Paris pattern, bearing the desired design. The pattern being removed, the depressions on the surface of the tile are filled with colored clays, and the surface is then shaved to remove all superfluities and ruggedness, leaving the pattern intact. The tile is then dried for two or three weeks, and finally fired by being exposed to an intense heat for 60 hours. See Tiles.

Enceinte, ŏn-săñt, in military engineering and in fortification, the continuous line of works which forms the main enclosure of a town or fortress. The term is also applied to the area within this line. See Fortification.

Encel'adus, son of Tartarus and Gæa in Greek mythology; one of the hundred-handed Titans who made war against the Gods, Jupiter slew him with a thunderbolt and buried him under Mount Ætna. The name Enceladus was given to the second satellite of Saturn, discovered by Herschel 28 Aug. 1789.

Encephalitis, an inflammation of the brain proper which may be localized or diffused, and results from coexistent intoxications, or following any acute affection such as ulcerative endocarditis, rheumatism, mumps, etc. It is quite probable that many cases of acute encephalitis occur in children, resulting in the well-known picture of infantile hemiplegia. The symptoms are very indefinite. There is headache, vomiting, somnolence. There may be coma or delirium, the symptoms all pointing to acute inflammation of the brain. Acute encephalitis is usually fatal. In many of the insanities, as acute mania, delirium, dementia paralytica, there is a form of encephalitis usually present. Localized encephalitis usually results in abscess. See ABSCESS; BRAIN.

Encephalocele, ĕn-sĕf'a-lō-sēl, a hernia or a protrusion of a portion of the contents of the cavity of the brain through an opening in the skull beneath the skin. At least three different forms are described: Meningocele, when the dura mater alone protrudes from the cavity, forced out by the pressure of the cerebrospinal fluid; hydrocephalocele, in which the tumor consists of an internal hydrocephalus; and encephalocele, which is made up of true brain-tissue with more or less fluid surrounding it. Most of these tumors are of congenital origin, due to insufficient union of the bones of the skull; a few are acquired later in life. Surgical procedure is the only efficient mode of treatment.

Enceph'alon. See BRAIN.

Enchasing, or **Chasing**, a process analogous to that of sculpture, being the art of enriching, beautifying and finishing, ornamental designs in raised work upon metal surfaces, especially gold and silver. When these designs have received their general form by casting or hammering they are ready for the skilled hand of the artisan and his chasing tools. These are of a great variety of shapes and sizes, fitted to correspond with the minute details of the most complex work. Some are grooved or checkered at the ends, and some of the gravers and burins are curved and blunt, while others taper to a needle-point. The worker possesses a set of hammers, big and little, graded in size to suit any kind of tool. To offset his alternating task of punching and carving he employs sand bags upon which to rest his work. In order that the form of hollow articles may not suffer injury during the operations they are filled with a composition of melted pitch and brick dust or rosin. Articles in copper and brass are sometimes filled with lead to give them firm support within. Fine steel blocks are often used to the same end. Excellent specimens of chased work are seen in pieces of ancient armor, and in vases and other ornaments in gold and silver-plate. Among the most beautiful are those executed by Benvenuto Cellini in the 16th century. Bronze, richly wrought, is rapidly taking its place beside gold and silver work.

Enchanter's Nightshade, a name common to plants of the genus *Circœa*, belonging to the order *Onagraceœ*, of which there are two American species, *C. lutetiana* and *C. alpina*. The former is about a foot and a half high, and has delicate ovate leaves, small white flowers tinged with pink, and small roundish seed-vessels covered with hooked bristles. It abounds in woods from Nova Scotia to western Ontario, south to Georgia and west to Nebraska. It is also called the bindweed nightshade. *C. alpina*, which is similar, but smaller and more delicate, is found in cold, moist shady woods throughout the northern hemisphere. Both plants are common in Europe and Asia. Neither has any affinity with the nightshades.

Enchondro'ma, a tumor made up largely of cartilage. See TUMOR.

Encho'rial Alphabet. See DEMOTIC ALPHABET.

Encina, Juan del, hoo-än' dăl ĕn-thē'nä, Spanish dramatist: b. Salamanca 1469; d. there 1534. His first volume of poems, 'The Song-Book,' contained also a dissertation on 'The Art of Castilian Poesy.' His lyrics are full of charm and lively wit. He wrote 14 dramas; eight of which are shepherd-plays or eclogues; the rest are pieces for Church holy seasons. He made the Jerusalem pilgrimage, and described it in the poem: 'Tribagia; or, the Sacred Way of Jerusalem' (1521). He has been styled "The father of the Spanish drama."

Encisco, Diego Ximenez de, dē-ā'gō he mĕn'āth ĕn-thēs'kō dā, Spanish dramatist: b. in Andalusia. He flourished in the 16th century, and his works are quite noted, though little is known of his life. His best-known play is 'The Medicis of Florence.'

Encisco, Martin Ferdandez de, mär-tēn fĕr-nän'dĕth dā ĕn-thē'sō, Spanish geographer: b. Seville about 1470; d. after 1528. He came to America in 1500; practised law in Santo Domingo and supplied funds to Alonso de Ojeda for the colonization of Tierra Firme, the region about the Isthmus 1509. Encisco followed in 1510 and founded the city Santa Maria la Antiqua del Darien. His soldiers revolting, he was arrested by Vasco Nunes de Balboa, and went to Spain, returning to Darien 1514 as alcalde, and opposing Balboa till the latter's unjust execution by Pedrarias Davila at Darien 1517. He was the author of 'Suma de Geographia, que treta de todas las partidas del mundo,' the first Spanish description of America which touched upon the difference in level of the two oceans.

Encke, ĕng'kĕ, **Erdmann**, German sculptor: b. Berlin 20 Jan. 1843; d. 1896. He was a pupil of the Berlin Academy and of Abert Wolff, his first piece being a group entitled: 'A German Struggling With Two Gauls.' He took a prize for the statue of Jahn in 1872, and was made professor at the Berlin Academy in 1883. His art was related to the school of Rauch, his temperament being at the same time realistic and poetical. Among his prominent works are a statue of the Great Elector, Frederick I. of Brandenburg, Town Hall, Berlin; a colossal statue of Queen Louise of Prussia, Thiergarten, Berlin; and the sarcophagi of Emperor William I. and Empress Augusta in the mausoleum at Charlottenburg.

Encke, Johann Franz, yō-hän fränts, German astronomer: b. Hamburg 23 Sept. 1791; d. Spandau 26 Aug. 1865. He studied under the astronomer Gauss, at Göttingen; during the war of liberation (1813–15) served as artillerist in the German army, and on the conclusion of peace was appointed assistant in the observatory of Seeberg, near Gotha. Here he calculated the orbit of the comet observed by Mechain, in 1786, by Miss Herschel in 1795, and by Pons in 1805–18. He predicted its return in 1822–25–28, and with each reappearance more data were afforded for computing its exact orbit, which, it was calculated, required three and a quarter years to complete. By comparison of the times of its earlier and later appearances, Encke was subsequently led to detect a gradual acceleration of its movement, amounting to about two and a half hours on each revolution. This acceleration he ascribed to a resisting medium, which sensibly affects the body of the extreme rarity of this comet, which is transparent to its centre. The fame of his two publications: ‘Die Entfernung der Sonne’ (1822), and ‘Der Venusdurchgang von 1769’ (1824), led to his appointment as director of the observatory of Berlin (1825), a position which he held till his death. Many of his works are contained in the ‘Astronomische Jahrbücher’ (1830–66), a publication during these years issued under his direction.

Enclosure, or conventual seclusion of nuns who have taken solemn lifetime vows, is guarded very strictly by the laws of the Roman Catholic Church. The conventual seclusion of monks is less strict, the prohibition of converse with the outer world being in their case limited to the exclusion of women from the interior of the monasteries and rigid rules on the observance of silence. The Council of Trent forbids nuns to leave their convents, even for a short time, on any account whatever save for a legitimate cause — a cause specified in the law — with the approval of the local bishop. And no person from outside, male or female, young or old, high or low, lay or clerical, is to be admitted within the *clausura* of a nunnery unless with leave in writing from the bishop or superior. By violation of this rule excommunication is incurred *ipso facto*. These rules, however, apply to regularly cloistered nuns, who take solemn life-vows of detachment from the world: they do not apply to the houses or convents of religious women whose work brings them in contact with the outside world, such as sisters of charity, of mercy, little sisters of the poor, and the like. In such religious institutes the spirit of the Tridentine law governs, not the letter.

Encratitæ, ĕn-krā'tĭ-tē (*continentes,* abstainers) a Gnostic sect of the 2nd century, disciples of Tatianus, who was himself a disciple of Justin Martyr, and like him, author of an *Apologia* on behalf of Christian believers. Tatianus held that the material world is essentially evil, proceeding from the evil principle. For him marriage was sinful and animal food an abomination; he employed water instead of wine in the eucharistic rite.

Encrinites, ĕn-krĭ-nī'tēz, fossil crinoids or sea-lilies, known as stone-lilies. See CRINOIDS.

Encyc'lical (*literæ encyclicæ*), a circular letter. The word used in an ecclesiastical sense means a letter addressed by the Pope to all the bishops in the world who are in communion with him, in which he condemns errors prevalent in the world, or explains the line of conduct which Christians ought to take in reference to practical questions pertaining to faith and morals. Leo XIII. issued a large number of encyclicals on such questions as, rights of labor, education, marriage, Bible study, etc. (See LEO XIII.) An encyclical differs from a bull or brief, in that the encyclical is to the bishops of the whole world, treats of matter of universal interest, and is of concern to the entire Church. A bull or brief is determined by circumstances, is of a special nature, and may be of particular value only to some locality. There is a difference in the form of an encyclical from that of a bull or brief,— that is, in the seals used, the signatures and the introductory words.

Encyclopæ'dia, Cyclopædia, or Cyclopedia. This word, formed from the Greek *en,* in, *kuklos,* a circle, and *paideia,* instruction, but not a native Greek compound, originally denoted the whole circle of the various branches of knowledge which were comprehended by the ancients in a liberal education (the *artes liberales* of the Romans). The distinction between the words encyclopædia and cyclopædia is almost too trifling to be comprehended. At a later period the word was applied to every systematic view, either of the whole extent of human knowledge or of particular departments of it. The want of such general surveys was early felt; and as knowledge increased they became still more desirable, partly for the purpose of having a systematic arrangement of the sciences in their mutual relations, partly for the readier finding of particular subjects; and, for these two reasons, such works were sometimes philosophically, sometimes alphabetically, arranged. The spirit of compiling, which prevailed in the Alexandrian School, soon led to attempts remotely allied to this, and Varro and Pliny the elder, among the Romans, composed works of a similar kind.

The honor of undertaking encyclopædias on a regular plan belongs to the Middle Ages, which produced not only a large number of cyclopædias of particular sciences, called *Summæ* or *Specula* (for example, the ‘Summa Theologiæ’ of Thomas Aquinas), but also a Universal Encyclopædia, such as had never been seen before. The indefatigable Dominican, Vincent of Beauvais, about the middle of the 13th century, exhibited the whole sum of the knowledge of the Middle Ages in a work — or rather three works — of considerable size — a real treasure to the inquirer into the literary history of the Middle Ages. An exceedingly popular work was the ‘De Proprietatibus Rerum’ of Bartholomeus de Glanvilla, an English Franciscan friar, which maintained its reputation from the year 1360 to the middle of the 16th century. In the 17th century various encyclopædic works were compiled, such as the Latin one of John Henry Alsted, ‘Encyclopædia vii Tomis distincta’ (Herborn 1620), a work in which the subjects are divided into 7 classes, and treated in 35 books. In 1674 appeared the first edition of Moréri's ‘Le Grand Dictionnaire Historique.’ In 1677 John Jacob Hoffman published at Basel his ‘Lexicon Universale,’ the first work of the kind in which a summary of art and science was presented in dictionary form. In 1697 appeared Bayle's famous ‘Dictionnaire Historique et Critique’ (Rotterdam, 4 vols.), a work which is still of great value. Among the greatest works of earlier date would have been reckoned the ‘Biblioteca Universale’ of Coronelli, had it been completed according to the original plan. It was to have appeared in 45 folio volumes, of which only seven were published (Venice 1701–6). More successful, especially in being brought to a completion, was the 'Grosses vollständiges Universallexicon aller Wissenschaften und Künste' (Grand Universal Lexicon of all the Arts and Sciences), commonly called Zedler's, from the person, a bookseller, who conducted it (Halle and Leipsic 1732–50, 64 vols.; Supplement 1751–4, 4 vols. folio). It has, on the whole, much merit. Lives of living men were included after Volume XVIII.

The first encyclopædia written in English and with the articles alphabetically arranged, was the 'Lexicon Technicum,' or an 'Universal English Dictionary of Arts and Sciences' (London 1704, 1 vol. folio), by John Harris, a London clergyman. This was a useful and popular work, though it omitted from its scope theology, biography, antiquity, and poetry. It was reprinted in 1708, and a second volume was added in 1710. Among other important encyclopædic works in English the following may be mentioned: Ephraim Chamber's 'Cyclopædia'; or an 'Universal Dictionary of Arts and Sciences' — a work published in 1728, in two volumes folio. A second and improved edition came out in 1738. Latterly it was revised and enlarged by Abraham Rees, in which form it was several times reprinted, being finally known as 'Rees' Cyclopædia,' and published in a number of volumes. Then was published the 'Encyclopædia Britannica.' Of this there have been nine editions. The first edition was completed in 1771, in three volumes, and the ninth edition was completed in 1889, in 24 volumes, and an index volume. The 'Edinburgh Encyclopædia' (1810–30, 18 vols.) was devoted particularly to the sciences and technology, and was conducted by Sir David Brewster. The 'Encyclopædia Metropolitana' (London, begun 1815, completed 1845, in 25 vols., was published in four divisions, according to a plan devised by the poet Coleridge). The 'London Encyclopædia,' by Thos. Curtis (22 vols.), and the 'Penny Cyclopædia' (29 vols.), appeared in 1833–46. Chambers' 'Encyclopædia' (in 10 vols.) was published in 1860, and a new edition appeared in 1902.

In the United States an early work was the 'Encyclopædia Americana,' edited by Francis Lieber, and published 1839–47 in 14 volumes. 'The American Cyclopædia,' edited by George Ripley and Charles A. Dana, appeared in 1858–76 in 16 volumes. The publishers of this work have since 1861 published the 'American Annual Cyclopædia,' designed to record the progress of science and the arts, and the world's history from year to year, and to serve as supplements to the 'American Cyclopædia.' It is in the same form as that work, octavo, and comprises about 800 pages per volume. 'Johnson's New Universal Cyclopædia' first appeared in 1874–7, in four imperial octavo volumes. It was especially strong in the departments of natural science — physics, chemistry, mechanics, etc.,— and American gazetteer matter. In its later form, 'Johnson's Universal Cyclopædia' (1893–5, 8 vols.), with a change of publishers, the work was thoroughly revised, by a corps of 36 editors, under the direction of Charles Kendall Adams. Then followed 'The International Cyclopædia' (New York 1884), which was succeeded by 'The New International Encyclopædia' in 17 volumes (1902), and later (1903) by the 'Encyclopedia Americana' in 16 volumes.

Of the French cyclopædias the most famous is the great 'Encyclopédie, ou Dictionnaire Raisonné des Sciences, des Arts, et des Métiers,' by Diderot and D'Alembert.' This was published in 35 volumes 1751–80. Not only information was given in these volumes, but opinions of the most radical character, hostile to the Church, subversive of religion, intensely antagonistic toward everything in the old order of things. The clergy and the court had fought the work, had even broken into it with alterations secretly made at the printers', and left no stone unturned to prevent its circulation. Yet Europe was filled with it, and shaken with the effects of it. It was an immense burst of everything which journalism to-day means; a fierce prophecy of changes which are still hanging; a wild proclamation of the problems of human aspiration and desire. Not only were the sciences pushed to the utmost by Diderot, but he made industry, labor, human toil in the shop, an interest unceasingly cherished. It was an explosion heralding the Revolution a quarter of a century later. Still more comprehensive is the 'Encyclopédie Méthodique, ou par Ordre des Matières' (Paris 1781–1832, in 166½ vols.), an aggregate of dictionaries rather than a single work. The French have also the 'Encyclopédie Moderne,' begun in 1824, finished in 1832, 26 volumes, and subsequently republished; the 'Encyclopédie des Gens du Monde' (1835–44), 22 volumes; 'Larousse's more recent and valuable 'Grand Dictionnaire Universel du XIX. Siècle,' 16 volumes folio (with two supplementary volumes); and 'La Grande Encyclopédie,' an extensive and excellent work which was completed in 1903. Of works published in Germany the most famous is 'Brockhaus' Conversations-Lexikon,' now in its 14th edition. It is equaled, if not surpassed, by the similar work of Meyer. The huge 'Allgemeine Encyklopädie der Wissenschaften und Künste,' originally edited by Profs. J. S. Ersch and J. G. Gruber, begun 1818, is not yet completed. Three sections of the alphabet are carried on simultaneously. Other German encyclopædias deserving mention are those of Pierer and Spamer. Similar works have also been published in Italy, Spain, Holland, Denmark, Norway, Sweden, Russia, etc.

The rapid advancement of the sciences and arts, and the proportionately rapid communication between all civilized nations, have made a general acquaintance with many different branches of knowledge more necessary than ever before. This is one of the chief causes which have produced in our time so many encyclopædias of various kinds, some very learned, and others more adapted for the general reader; some embracing all the sciences and arts, others only single branches.

End-brain, a name given to the front part of the brain, which corresponds to the fore-brain or telencephalon. See Brain.

End-organs, important nerve-structures specially designed for particular purposes. Thus the taste-buds in the mouth and tongue, the touch-bulbs in the fingers, and the muscle-plates in the muscles are special forms of nervous end-organs. There is a vast variety of nervous end-organs found in the special glands, such as the secretory glands of the skin of the mucous membranes, in the liver, the spleen, the kidneys, etc.

Endarteritis, ĕn-där-tē-rī′tĭs. See ARTERITIS; BLOOD VESSELS.

Endeman, Wilhelm, vĭl′hĕlm ĕn′dē män, German jurist: b. Marburg, Hesse, 24 April 1825. He studied at Heidelberg and was professor of law at Jena 1862–7 and at Bonn in 1876. He was a member of the Reichstag 1871–3. His writings on German commercial law are highly esteemed. Among his works are: 'Die Beweislehre des Zivilprozesses' (1860); 'Der deutsche Zivilprozess' (1878-9); 'Die Entwicklung des Beweisverfahrens im deutschen Zivilprozess' (1895).

Endem′ic (Gr. «prevailing among the people»), a name often applied to diseases which attack the inhabitants of a particular district or country, and have their origin in some local cause, as the physical character of the place where they prevail, or in the employments, habits, and mode of living of the people. Every part of the world, every climate, and every country, has its peculiar endemics. Thus the tropical and warm climates are subject to peculiar cutaneous disorders, eruptions of various kinds, because the constant heat keeps up a strong action of the skin. In northern climates eruptions of the skin occur, but they are of a different kind. Thus in all the north polar countries, especially in Norway, a kind of leprosy, the *radesyge,* is prevalent, arising from the coldness and humidity of the climate, which dispose the skin to such disorders. Hot and moist countries generate the most violent typhoid and putrid fevers; the West Indies and some of the South American coasts, for instance, produce the yellow fever. In different parts of the United States intermittent fevers, arising from local malarial conditions, are common, as they are in countries generally in places that are damp and not warm, on marshes and large rivers, etc. Places in a more dry and elevated situation, northern countries particularly, are peculiarly subject to inflammatory disorders. In countries and districts very much exposed to currents of wind, especially in mountainous places, we find at all seasons of the year rheumatisms, catarrhs, and the whole train of complaints which have their origin in a sudden stoppage of the functions of the skin. In large and populous towns we meet with the most numerous instances of pulmonary consumption. In cold and damp countries like England, Sweden, and Holland the most frequent cases of croup occur.

Diseases which are endemic in one country may also appear in others, and become epidemic if the weather and other physical influences resemble those which are the causes of the endemic in the former place; the climate being for a time transferred, as it were, from one to the other. Endemic disorders in some circumstances become contagious, and thereby spread to other persons, and may be transplanted to other places, the situation and circumstances of which predispose them to receive these disorders. This is known by the migrations of diseases, the spreading of leprosy from Oriental countries to Europe, and the like.

It is favorable to the cure of obstinate disorders for the invalid to remove to a climate where his particular complaint is rare. Thus it is customary for people attacked with pulmonary complaints to remove to localities where the air is pure and dry, and sunshine abundant. So it is of advantage to the consumptive to exchange unwholesome city air for pure air in the country. Modern sanitation is learning to deal with conditions which, alike in populous and sparsely peopled places, have hitherto bred diseases; so that immunity from fatal disorders may be said to show the good results of sanitary science, as do also the improved statistics of longevity.

Ender, ĕn′dėr, **Eduard,** Austrian artist: b. Vienna 1824. A son and pupil of Johann Ender, (q.v.), he studied at the Vienna Academy, becoming a historical and genre painter. Among his works are: 'Wallenstein and Seni' (1844); 'Corbeille de Mariage' (1850); 'Tasso at Court of Ferrara' (1852); 'Francis I. in Cellini's Studio' (1854); 'Emperor Rudolph II. and Tycho Brahe' (1855); 'Shakespeare Reading Macbeth at Court of Elizabeth'; 'Emperor Joseph II. Meeting Mozart'; 'Schiller at Court of Weimar'; 'Rembrandt at his Studio'; 'Elizabeth and Van Dyck'; 'Game of Chess' (1857); 'Marie Antoinette's Farewell of Maria Theresa.'

Ender, Johann, Austrian artist: b. Vienna 4 Nov. 1793; d. 16 March 1854. As a portrait painter he was successful at an early age. In 1818–19 he made a tour of Italy, Turkey and Greece, remaining in Rome 1820–6. Upon his return to Venice he devoted his attention to miniature and historical paintings, being professor at the Academy from 1829 to 1850. Among his works are: 'Madonna with Slumbering Christ-Child,' Vienna Museum; 'Marcus Aurelius on his Death Bed' (1814), Esterhazy Gallery; his masterpiece, 'The Crucifixion,' a fresco in the Vienna Cathedral; 'Orestes Pursued by the Furies' (1815); 'Minerva Showing Ithaca to Ulysses' (1816); 'Assumption'; 'Sleeping at Christ's Sepulchre' (1817); 'Judith'; 'Bacchus finding Ariadne'; and many portraits.

Ender, Thomas, Austrian artist: b. Vienna 4 Nov. 1793; d. there 28 Sept. 1875. He was twin brother of Johann Ender (q.v.). He also studied at the Vienna Academy, becoming a noted landscape painter. He won the grand prize at the Vienna Academy 1816. Going to Brazil in 1817, he brought back nearly a thousand drawings and water colors. In 1836 he became corrector and later professor at the Vienna Academy, filling that chair until 1849. Among his works are: 'View of Grossglockner'; 'Castle Tyrol'; 'Coast of Sorento'; 'View of Rio Janeiro,' Vienna Academy; 'Chapel in the Woods,' National Gallery, Berlin.

En′derby Land, a region in lat. 65° 57′ S., lon. 47° 20′ E., named by John Briscoe in 1831, when on a whaling voyage, in honor of his employer, Samuel Enderby. Briscoe could not approach within 20 or 30 miles, and was unable to say whether it was an island or a strip of continental coast. It was first discovered by Dirk Gherritoz, in 1599, and named for him.

Ender′mic, a term designating a form of medication once much in vogue, but now almost abandoned, consisting in raising a blister upon the affected part and applying to the raw surface the remedy to be absorbed. See HYPODERMIC.

En′dicott, Charles Moses, («JUNIUS AMERICANUS»), American historical writer: b. Danvers, Mass., 1793; d. Northampton, Mass., 1863. He contributed to the 'New England Historical and Genealogical Register' and to the Boston *Gazette*. He wrote a 'Life of John Endicott'; 'The Persian Poet, a Tragedy'; 'Essays on the Rights and Duties of Nations'; and 'Three Orations.'

Endicott, John, American colonial governor: b. Dorchester, England, 1589; d. Boston, Mass., 15 March 1665. He was sent out to this country by the "Massachusetts Company" to carry on the plantation at Naumkeag, or Salem, where he arrived 6 Sept. 1628. In April 1629 he was chosen governor of "London's plantation"; but in August it was determined to transfer the charter and government of the colony to New England, and Winthrop was appointed governor. Endicott was deputy-governor of the Massachusetts colony 1641–4, in 1650, and 1654; and was governor in 1644 and 1649, 1651–4, and 1655–65. He was bold and energetic, a sincere and zealous Puritan, rigid in his principles, and severe in the execution of the laws against those who differed from the religion of the colony. So averse was he to everything like popery that he cut out the cross from the military standard. He was opposed to long hair, insisted that the women should wear veils in public assemblies, and did all in his power to establish what he deemed a pure Church. In 1659, during his administration, four Quakers were put to death in Boston.

Endicott, William Crowninshield, American lawyer; b. Salem, Mass., 19 Nov. 1826; d. Boston 6 May 1900; was a descendant of John Endicott (q.v.), the Puritan governor of Massachusetts. He was graduated at Harvard College in 1847; was an unsuccessful candidate for governor of Massachusetts, on the Democratic ticket, in 1884; and was appointed secretary of war in President Cleveland's cabinet in 1885.

Endive, ĕn'dĭv (*Cichorium endivia*), an annual or biennial herb of the natural order *Compositæ*. It is an East-Indian annual or biennial, with a rosette of smooth radical leaves, more or less lobed or cut, blue axillary sessile flowers, and grayish angular seeds. It has long been cultivated as a salad, for which use it probably ranks in Europe next to lettuce, but not quite so high in America. It is as easily cultivated as lettuce, but must be blanched, either by loosely tying the outer leaves up over the inner ones or by covering the plants with large drain-tiles or similar tubes. Of the numerous varieties, those that naturally are most curly-leaved, and that ordinarily develop a white centre without blanching, are the most esteemed. The leaves are also used as a pot-herb and as an ingredient in soups, stews, etc.

Endless or **Perpetual Screw,** a mechanical contrivance, consisting of a screw, the thread of which gears into a toothed wheel at an oblique angle corresponding to the pitch of the screw. It derives its name from the endless recurring effect its thread produces when in motion. It is in general use as a means of producing slow motion in the adjustments of machines rather than as a transmitter of great power.

End'lich, Gustav Adolf, American jurist: b. Alsace Township, Berks County, Pa., 29 Jan. 1856. He was educated in Germany and at Princeton; studying law and being admitted to the bar in 1877. He was elected judge of the 23rd judicial district, Pennsylvania, 1889, and re-elected 1899. He has published: 'The Law of Building Associations' (1882); 'The Law of Affidavits of Defense in Pennsylvania' (1884); 'Woodward's Decisions' (1885); 'Commentaries on the Interpretation of Statutes' (1888); 'Rights and Liabilities of Married Women in Pennsylvania' (1889).

Endlicher, ĕnd'lĭн-ĕr, **Stephen Ladislas,** Hungarian botanist: b. Hungary 24 June 1804; d. Vienna 28 March 1849. He was destined for the priesthood, but in 1827 began botanical and linguistic studies, and in 1840 became professor of botany in Vienna. Much disturbed by the events of 1848, he fell into melancholy, and in 1849 put an end to his own life. His 'Genera Plantarum' (1836–40) has had great influence on succeeding botanists.

Endocardi'tis, inflammation of the endocardium or serous membrane lining the valves and internal surface of the heart. See HEART.

Endog'amy, a custom among some savage peoples of marrying only within their own tribe. Opposed to exogamy.

Endogens, ĕn'dō-jĕnz, a name for monocotyledons, referring to the mode of growth of the stem. See BOTANY; MONOCOTYLEDONS.

Endometri'tis. See WOMB.

Endoneurium, ĕn-dō-nū'rĭ-ŭm, the delicate coat of connective tissue-cells found in and around the nerve-fibre bundle. See NERVE FIBRES.

Endor, ĕn'dėr, a village of Palestine, four miles south of Tabor; now a poor mud hamlet. It was the place which Saul visited (1 Sam. xxviii. 7) to consult the "woman with a familiar spirit" previous to his fatal engagement with the Philistines.

Endoscope, in surgery, a general term for an instrument for the examination of internal parts. It consists of a tube and an apparatus for lighting. The most serviceable is that devised by Nitze and Leiter.

Endosmo'sis. See OSMOSIS.

Endothelioma, ĕn-dō-thē-lĭ-ō'ma. See TUMOR.

Endothe'lium, a modified form of the cells lining certain internal organs. Such are the internal lining membranes of the heart and blood vessels, the joints, and other closed cavities. Endothelium is a modification of epithelium (q.v.).

Endym'ion, in classical mythology, according to some a huntsman, according to others a shepherd, and according to a third account a king of Elis. One tradition is that he asked of Zeus eternal youth and eternal sleep, and that Selene (the moon) saw him sleeping and became enamored of him. Others relate that Selene herself, charmed by his beauty, conveyed him to Mount Letmus in Caria and threw him into a perpetual sleep in order that she might kiss him whenever she pleased. The legend is the subject of Keats' 'Endymion.'

Enemata, fluid substances passed into the rectum and large intestine for cleansing, for medication, or for nutrient purposes. For the treatment of chronic constipation, enemata of cold or hot water, water and soapsuds, water and glycerine, are found to be of great service. Almost any remedial substance capable of solution and absorption may be placed in the rectum or large intestine to affect the parts locally or to exert a general action on the body. Almost all remedies that are taken into the stomach may be taken by means of enemata. The dose has to be somewhat larger in most instances. For the treatment of pinworms, diarrhœa, and dysentery enemata are invaluable. In medicine the lower bowel may be used much oftener than it is. In acute colicky pains from "wind" in the bowels there is nothing better, as a rule, than a hot enema of at least two quarts, at a temperature of from 116° to 118° F. As the lower bowel is not provided with digestive juices, when nutrient enemata are to be given the insoluble food-substances should be so converted as to render them capable of absorption — hence all gruels, eggs, milk, etc., to be used should first be predigested by peptic or pancreatic ferments. A special form of enema, consisting of hot (116° to 118° F.) salt solution (1 teaspoonful of salt to 1 pint of water), allowed to pass in and out of the bowel slowly and made to ascend some distance, is of immense service in cases of surgical shock, in profuse bleeding, and in cases in which the kidneys refuse to secrete urine. This is termed enteroclysis (q.v.). Enemas for cleansing the bowel should be copious; those for nutrient purposes should be small — not over half an ounce. Enemas may be given by the ordinary fountain syringe, by a Davidson syringe, or by a rubber or glass syringe.

Enemy. See War, Laws of.

Energet'ics, that branch of mathematical physics which deals with energy and its transformations. A general theory of energetics, discussing the quantitative relations that hold true in all imaginable transformations, was given by Rankine. Consult: 'Miscellaneous Scientific Papers,' p. 209. See Energy; Perpetual Motion; Thermodynamics.

Energumen, ĕn-ėr-gū'mĕn, a person controlled or "worked up" (ἐνεργούμενος) by evil spirits. The word is in common use in the writings of the Greek and Latin fathers: it is equivalent to the (δαιμονιζόμενος) (possessed by a devil) of the New Testament. In the 3rd century the churches kept registers of their energumens and dealt with them much as though they were lepers: they were supported by the alms of the faithful and lodged in dwellings near the churches; so we learn from the acts of the Council of Orange 529 (*Concilium Arausicanum*). Various modes of exorcizing were employed by the special ministers called Exorcists or by the bishop and his clergy, for the relief of the energumens; these, until cured, were denied the sacraments of the Church. See Exorcism.

E'nergy, in physics and theoretical mechanics, that attribute of a body, or of a material system, by virtue of which the body or system can do work; work being simultaneously defined as the overcoming of resistance through distance. A raised weight can do work by falling to the ground; a coiled spring can do work in unwinding; a mass of compressed air can do work in expanding down to the normal atmospheric pressure; and similar examples might be multiplied indefinitely. All of these bodies, or systems, that can do work by changing their position, or their shape, or their state, are said to possess "energy"; and the energy that a body possesses is measured strictly by the quantity of work that it can do. The unit that is adopted in the measurement of work depends upon the nature of the problem that is under consideration. In modern scientific investigations the unit of work is commonly the erg, which is defined as the work that is done in overcoming a resistance of one dyne, through a distance of one centimetre. In ordinary engineering operations, the unit of work commonly employed (at least in the United States and in England) is the foot-pound, which is defined as the amount of work that is done in overcoming a resistance of one pound, through a distance of one foot. The foot-pound is not as precise and definite a unit as the erg, because the attraction that the earth exerts upon a pound of matter varies with the latitude and with the elevation above the sea, and hence the foot-pound varies in the same manner. The variation is not great enough, however, to destroy the usefulness of the foot-pound as a unit of work in ordinary engineering operations, and hence this familiar unit is not likely to be superseded, for ordinary purposes, unless the metric system is brought into general use in the United States. There is no great difficulty in understanding that a weight can do only a definite amount of work in falling from one level to another, or that a spring can do only a definite amount of work in unwinding; for we all know that clocks have to be wound up regularly, and that a small waterfall will not yield the same power as a big one that has the same difference of level between its top and its bottom. In the case of a body that falls freely through the air, however, the fact that the energy that it had in virtue of its elevated position is not lost is not so evident. It is true that the energy, in this case, is not immediately expended in overcoming frictional resistance, nor in doing work of any obvious and visible kind. Nevertheless it is not lost; for it is expended in giving the moving body its velocity. A moving body possesses energy in virtue of its motion, and work must be done by it before it will stop. Thus a railroad train, moving at high speed, cannot be brought to rest at once, because the energy of motion that it possesses must first be expended in overcoming the resistance of the brakes, or the natural frictional resistance of its axles in their journals and its wheels upon the tracks. The energy that a body possesses in virtue of its motion is called "kinetic energy," that which it possesses on account of its position, or its state of strain, being called "potential energy," by way of distinction. The amount of work that must be done upon a body of mass M, which is moving with a speed V, in order to bring it to rest (that is, its "kinetic energy"), can easily be shown to be given by the formula Kinetic Energy $= \frac{1}{2} MV^2$.

The conversion of kinetic energy into potential energy and back again, is well illustrated in the pendulum. At the lowest point of its swing, the energy of a pendulum is entirely kinetic; while at the highest point of the swing, and just as the motion is about to be reversed, the energy is entirely potential.

Conservation of Energy.— The physical law that is known by this name merely asserts that the total amount of energy in any isolated system is absolutely invariable in amount. Energy may be added from without, or abstracted in a similar manner; but so long as no external influences are permitted to interfere, the total quantity of energy within the system is incapable of either increase or diminution. In the case of the pendulum this is easily admitted; but other systems are easily imagined, in which the truth of the law is by no means obvious. For example, a tightly-wound watch-spring possesses potential energy, in virtue of which it may be caused to drive a train of wheels, and to do work. But suppose the coiled watch-spring is dissolved in an acid, and meanwhile secured in some manner so that it cannot unwind. We cannot assume that the solution that is ultimately obtained is any different, whether the watch-spring was coiled before dissolving, or not. What becomes of the energy in the spring? This question would be best answered by experiment; but in the absence of experimental data the conjecture may be reasonably made that the two sides of the spring, being in different states of strain, act like plates of different metals when immersed in the acid, and give rise to electric currents through the liquid, whose combined chemical and thermal effects correspond precisely to the potential energy that was stored in the spring by winding. The simpler case of a body falling freely through the air is also somewhat confusing at first thought, because although it may be admitted that the potential energy is stored up by accelerating the body while it is falling, it is by no means evident that the energy is not annihilated as soon as the body strikes the ground. As a matter of fact, the energy of the falling body is converted into heat when the visible motion is suddenly arrested, and the body and the ground immediately around it are warmed by an amount that corresponds precisely to the kinetic energy that the body had immediately before the arrest. This explanation is not merely speculative, for it rests upon sound experimental evidence. The arrest of a cannon-ball is accompanied by the generation of enormous quantities of heat, and the woodwork on battle-ships is often set afire in consequence of the mere impact of projectiles. The water at the bottom of a waterfall is measurably warmer than that at the top; and the rise in temperature that is observed when a falling mass of lead is suddenly arrested was used by Hirn with remarkable success for the determination of the mechanical equivalent of heat.

The idea that energy cannot be created appears to have been familiar to Galileo, who inferred the fact from a careful study of the simple machines that were in use in his day. There appeared to be many cases in which energy is destroyed, however, and the indications were, in fact, that all mechanical energy is gradually wasted away by frictional losses and by others of like nature. In cases in which these losses do not exist, or are negligible, the idea of the conservation of the energies of a system, and of the perpetual transformations of kinetic energy into potential energy and the reverse, proved to be of the greatest service in simplifying the theoretical discussion of many problems in mechanics, even before the modern theory of heat was formulated. The motions of the celestial bodies, for example, are much more easily described by the aid of the principle of conservation of energy than they could be without it. The extension of that principle so as to cover all the cases in which it had previously appeared to be violated could not be made until the fact was recognized that heat is not a substance; for, obviously, it was impossible that a substance could be converted into mechanical energy. In the first years of the 19th century Rumford made experiments tending to prove that heat is not a substance, and he appears to have been convinced, in his own mind, of the correctness of his novel views. A quarter of a century later Carnot appears to have reached the same conclusion, if we may judge from the note-book that he left among his papers. It was not until about 1840, however, that the great steps were taken that led to the establishment of our present views. Several eminent names are connected with these beginnings of the modern theory of heat, and it is difficult to apportion the credit among them justly. Prominent among these names are those of Séguin, Mayer, Colding, and Joule; but it is undoubtedly to Mayer and Joule that we are chiefly indebted for the new ideas, and controversy has been mainly confined to the discussion of the priority and the relative importance of the contributions of these two men.

Dr. Julius Robert Mayer, an obscure physician of Heilbronn, Germany, who had had some professional experience in the island of Java, had observed that the venous blood of the Javanese often exhibits the brilliant red color that is commonly observed only in the highly oxygenated blood of the arterial circulation; and after much reflection he came to the conclusion that this is because a lesser amount of oxidation suffices to maintain the temperature of the body in a hot climate than would be required in a cooler one. These observations were made in the summer of 1840. In May, 1842, he published, in Liebig's 'Annalen,' a paper entitled 'Remarks on the Forces of Inorganic Nature,' in which he gave a preliminary account of his discovery. Here he presents the general outline of the new theory very clearly, and the grasp of the subject that he displays at this early date is truly wonderful. The locomotive itself was then a great novelty, but he uses it to illustrate the transformation of heat into mechanical energy and back again in the following sentence, which would be a credit to the most advanced physicist of to-day: "Our locomotives may be compared to distilling apparatus; the heat beneath the boiler passes into the motion of the train, and is again deposited as heat in the axles and wheels." In 1845 he published a second and much more remarkable paper entitled 'Organic Motion in its Connection with Nutrition,' in which he gives a detailed calculation of the mechanical equivalent of heat, from the known specific heats of air.

The contributions of James Prescott Joule, of Manchester, England, to the mechanical theory of heat and the conservation of energy were the natural outcome of investigations that he had been making upon the heating effects of electric currents. His first paper that distinctly enunciated the new conception of heat as a form of energy was read at Cork, in 1843, before the British Association, and was entitled 'On the Calorific Effects of Magneto-Electricity, and on the Mechanical Value of Heat.' As first written it was very involved, and Faraday, who appears to have failed to grasp its exceeding importance, advised Joule not to submit it. He did submit it, however, and in it he gave a number of estimates of the mechanical equivalent of heat. The paper apparently did not greatly impress either the British Association or the outside world; for when Joule brought the subject up again before the same association in 1847 he had an experience that is best described in his own words: "The chairman suggested that, as the business of the section pressed, I should not read my paper, but confine myself to a short verbal description of my experiments. This I endeavored to do, and discussion not being invited, the communication would have passed without comment if a young man had not risen in the section, and by his intelligent observations created a lively interest in the new theory." The young man was Lord Kelvin, then simply William Thomson, two years out of college. In later years Joule obtained far better values for the mechanical equivalent of heat, and spent much of his time devising and executing new methods for its determination.

In England and the United States Joule is commonly credited with the discovery of the true nature of heat; but in Europe the honor is given to Mayer. Tyndall compares the two very fairly. "Withdrawn from mechanical appliances," he says, "Mayer fell back upon reflection, selecting with marvelous sagacity, from existing physical data, the single result on which could be founded a calculation of the mechanical equivalent of heat. In the midst of mechanical appliances, Joule resorted to experiment, and laid the broad and firm foundation which has secured for the mechanical theory the acceptance it now enjoys. A great portion of Joule's time was occupied in actual manipulation; freed from this, Mayer had time to follow the theory into its most abstruse and impressive applications. With their places reversed, however, Joule might have become Mayer, and Mayer might have become Joule."

In 1847 Hermann Helmholtz published his remarkable paper entitled 'On the Conservation of Energy,' in which the subject was presented with great generality and clearness, and which had a profound influence in spreading the new doctrine which taught that no energy is ever created or annihilated, but that we have to do merely with endless transformations of it from one form into another. Attempts have been made to deduce the principle of the conservation of energy from the general laws of mechanics, and in many special cases these attempts have been successful, though they cannot be in all cases, because systems are easily imagined in which the law is not fulfilled. The point is, however, that these imaginary, non-conservative systems apparently do not exist in nature. In allusion to the two-fold nature of the subject (that is, the mathematical and physical aspects), it has been humorously said that everybody now believes firmly in the conservation of energy, because the mathematicians believe it to be a fact of observation, while the physicists believe it to be a theorem in mathematics. It is now generally admitted, however, to be a fact of observation, whose truth or falsity is to be established by experiment. Helmholtz proved that in any system composed of particles moving about in paths or orbits, and subjected only to "central forces" (that is, to forces that act always toward fixed centres or foci, or which act, between every pair of particles, along the line adjoining their centres), the energy must be conserved, if the ordinary laws of theoretical mechanics hold true for the motions of the particles of which the system consists. Hence, if it be admitted that all matter consists of atoms that act upon one another only by forces that are central, a long step has been taken toward proving the law for all material systems. Unfortunately, however, we are not sure that central forces are the only ones that act upon the atom. It is an interesting fact that it was the study of the processes of organic nature that gave Mayer his first inspiration concerning the true nature of heat, and yet it is precisely here that the only doubt as to the entire generality of the law of conservation now exists. The most general test that can be applied to a system to enable us to judge from theoretical considerations whether it is conservative or not, is this: Let the system be protected from external influences, and then, at a given instant, conceive the motion of every one of its particles to be precisely reversed in direction, without being modified in any other way. If, when left to itself, the system would then retrace its previous history so that the events of that history would recur in reverse order, the conservation of energy is rigorously fulfilled in it. If, on the other hand, the system would not so retrace its history, we cannot affirm that it is conservative, but must test the point by a direct appeal to experiment. Now, although this crucial condition of reversibility is frequently (and probably universally) fulfilled in inorganic nature, we certainly cannot assert it to be true in connection with living matter, not even with respect to the meanest fungus. Hence we cannot, from reasoning based on the inorganic world alone, draw any sound conclusion whatever about the conservation of energy in the organic changes that occur in living tissues. To reach such conclusions for the living animal, we must weigh and analyze the food administered and the excreta given off; we must determine the oxygen absorbed and the carbon dioxide and other products exhaled; and we must measure the heat given out, and the external work performed. When these things have been weighed, measured, and analyzed for a sufficient period and with the necessary precision, then, and then only, shall we be competent to affirm or deny the truth of the conservation of energy in the animal machine. Such data are difficult to obtain, but much has been done in this direction, and while we are not yet prepared to establish the fact, beyond controversy, that energy is conserved in the animal body, all the data that we have point to this conclusion, and it is now commonly admitted to be true. Consult: Stewart, 'The Conservation of Energy.' See PERPETUAL MOTION; THERMODYNAMICS.

Energy, Conservation of. See ENERGY.

Eneuresis, a symptom of many diseases of the bladder resulting in incontinence or involuntary passage of urine. It is a prevalent malady of childhood and only becomes of importance after the period of infancy, when the child should have learned to control the bladder. The control of the bladder is in part a matter of conscious effort, and has its representation in the higher brain-centres. Bladder-control is also exercised by that portion of the sympathetic nervous system found in the solar and sacral plexuses, and likewise in a number of cells in the spinal cord, situated in the lumbar region. Interference with the action of any or all of these centres may result in eneuresis. Disease of the spinal cord may cause excessive irritation of the sympathetic nervous system, and may result in nocturnal eneuresis; and the cutting off of the cerebral control may also bring about this condition. During deep sleep the cerebral control is usually cut off, accounting thus for the prevalence of eneuresis in deep sleep in children. Very frequently the immediate cause of eneuresis is some form of local irritation. This is particularly prevalent in young girls, and should always be removed, if possible, in the treatment. Drug medication is extremely unsatisfactory for this condition. The most efficient measures consist in building up the general nervous system of the patient by tonics, cold baths, and exercise in the open air.

Enfantin, ŏṅ-fŏṅ-tăṅ, **Barthélemy Prosper,** French socialist of the Saint Simon school: b. Paris 8 Feb. 1796; d. there 31 Aug. 1864. After the July revolution of 1830 Enfantin associated himself with Bazard for the active propagation of Saint-Simonism. Bazard expounded it in its relations to philosophy and politics; Enfantin mainly in its relations to the social state. Soon, however, a schism broke out between the two on the question of marriage and the relation of the sexes, for his views on which Enfantin was, in 1832, sentenced to two years' imprisonment and to pay a fine of 100 francs. Being released at the expiration of a few months, he went to Egypt. He was subsequently appointed a member of the scientific commission for Algiers, and on his return from Africa wrote 'Colonization of Algeria' (1843). After the revolution of 1848 he edited the journal 'Public Credit.' Other works by him are: 'Economie politique, et politique Saint Simonienne' (1831); 'La Religion Saint Simonienne' (1831); 'Morale' (1832); 'La livre nouveau' (1832).

Enfeoffment, ĕn-fĕf'mĕnt, the act of bestowing or conveying the fee-simple of any estate; or the instrument or deed by which the fee-simple of an estate is conveyed. See FEE-SIMPLE.

Enfield, William, English Nonconformist clergyman: b. Sudbury, England, 29 March 1741; d. Norwich, England, 3 Nov. 1797. In 1763 he became pastor to a congregation at Liverpool, and in 1770 became resident tutor and lecturer on belles-lettres at the academy at Warrington, where he remained for several years, and published several works, including his well-known 'Speaker.' Here he also drew up 'Institutes of Natural Philosophy,' theoretical and experimental. In 1791 he published his 'Abridgment of Bruckers' History of Philosophy.'

Enfield, Conn., town, in Hartford County; on the Connecticut River, and the New York, N. H. & H. R.R.; 20 miles north of Hartford. Its chief manufactures are carpets, shoddy, powder, supplies for undertakers, and bicycles; and it has large brick works. A large amount of the now celebrated Connecticut tobacco is here prepared for use and shipped to different parts of the world. Shaker Station is a part of the town (see SHAKERS). Pop. 6,715.

Enfield, England, a market town in the county of Middlesex; on New River, nine miles northeast of London. Enfield is the seat of the well-known government manufactory of rifles and small-arms, and the "Enfield rifle" used in the British army is made here. Some noted people have lived in Enfield. See D'ISRAELI; LAMB; KEATS. Pop. (1901) 42,738.

Enfield Rifle, a muzzle-loading rifle used in the British army prior to the introduction of the breech-loading system. It was also used in the United States during the Civil War by the Northern army, when Springfields could not be obtained, and by the Confederate army. In England large numbers of these rifles were converted into breech-loaders on the Snider principle, and were known as the Snider-Enfield or simply Snider.

Enfilade, ĕn-fĭ-lād' (from the Fr. *enfiler*), in the military art, is used in speaking of trenches or positions which may be raked by the enemy's shot along the whole length. In conducting the approaches at a siege care must be taken that the trenches be not enfiladed from any part of the place besieged. To avoid this they are generally cut in a zigzag.

Enfleurage, ŏṅ-flė-räzh, in perfume-making, the method of extracting, by contact and absorption, the scents of flowers used for perfumery. For this purpose wooden frames containing glass smeared with pure grease are filled with flowers, which are allowed to remain from one to six days. The grease gradually absorbs the scent, the flowers being renewed from time to time. The scent is afterward separated from the grease by soaking the latter in strong spirits of wine. Sometimes wire frames covered with cotton cloths, saturated with fine olive-oil, are used instead of glass. In this manner the most delicate odors are extracted from flowers, which would be lost in the process of distillation.

Eng and Chang. See SIAMESE TWINS.

Engadine, ĕn-gä-dēn, a beautiful valley in Switzerland, in the Grisons, on the banks of the Inn, bordering on the Tyrol. The language generally spoken is the Ladin, a branch of the Romanic tongue. Several towns and villages are situated in the valley, which is visited by numbers of strangers on account of its picturesque beauty and its mineral springs. Pop. 12,503.

Engano, ĕn-gä'ño, an island of the Malay Archipelago, 60 miles south of Sumatra. It is covered with forests and surrounded by coral reefs; area, including several small adjacent islands, 300 square miles. The natives are Malays. Pop. 6,410.

Engedi, ĕn-gē'dī or ĕn'gē-dī (Heb. "Fountain of the Goat"), on the western shore of the Dead Sea; about 30 miles southeast of Jerusalem. The modern Arabic name is Ain-Jidi. The ancient name was applied also to the eastern part of the Wilderness of Judah. The city, in the time of Abraham, was called Hazazon-tamar, the tamar meaning palm-tree. In 1 Samuel mention is made of David fleeing to the wilderness of En-gedi to escape from Saul.

Engel, Carl, German-English writer on musical topics: b. near Hanover 6 July 1818; d. Kensington, London, 17 Nov. 1882. After a general musical education as pianist, organist and composer he removed to England and settled in London (1850). Here he studied the history of national music and musical instruments. Among his works are: 'The Music of the Most Ancient Nations' (1864); 'Introduction to the Study of National Music' (1866); 'Musical Myths and Facts' (1876); 'Researches into the Early History of the Violin Family' (1883).

Eng'el, Eduard, German literary critic: b. Stolp, Pomerania, 12 Nov. 1851. He made a German translation of 'Italian Love-Songs' (1875); and wrote 'Lord Byron: An Autobiography from Journals and Letters' (1876); 'Psychology of French Literature' (1884); 'Did Bacon Write Shakespeare's Plays?'; 'History of English Literature: With Appendix, American Literature'; 'Wall to Wall' (1890); and 'Exiled and Other Stories.'

Engel, Johann Jakob, yō'hän yä'kōb, German prose writer: b. Parchim 11 Sept. 1741; d. there 28 June 1802. On the accession of King Frederick William III. of Prussia, whose tutor he had been, he was invited by his former pupil to Berlin, where he made himself exceedingly useful in the Academy of Sciences by his writings. Among his philosophical works may be mentioned his 'Philosoph für die Welt,' distinguished for acute observations on men and manners, enlivened by elegant illustrations. Of a similar character is his 'Mirror for Princes' (Fürstenspiegel). His 'Ideen zu einer Mimik,' full of taste, acuteness, and knowledge of human nature, may be regarded as a kind of manual for players. He also wrote several plays — 'Der dankbare Sohn'; 'Edelknaben,' etc. His 'Lorenz Stark,' a novel, is a masterly picture of life and manners. A complete edition of his works appeared at Berlin (1801–6).

Engel, Karl Dietrich Leonard, German musician and writer: b. Grand Duchy of Oldenburg 21 Feb. 1824. He went to Russia as a violin virtuoso at the age of 18, becoming a member of the Imperial Orchestra at St. Petersburg at 22, and later its concert-master. He went to Dresden in 1869 and took up his residence there. Among his works are: 'Deutsche Puppen Komödien' (1874–93); 'Das Volksschauspiel Doktor Johann Faust' (2nd ed 1882); 'Zusammenstellung der Faustschriften vom 16. Jahrhundert bis Mitte' (1884); 'Die Don Juan Sage auf der Bühne' (1887).

Engelbrechtzen, ĕng'ĕl-breʜt-zĕn, **Cornelis,** Dutch painter: b. Leyden 1468; d. there 1533. He was the son of the wood-engraver Engelbert, and the teacher of Lucas, being the earliest known painter in Leyden. Many of his works were destroyed during the Reformation, but among his authentic paintings are: Altarpiece with 'Crucifixion,' and altarpiece with 'Pieta,' Town Hall, Leyden. Doubtfully attributed to him are: 'St. Leonard,' Antwerp Museum; 'Crucifixion,' old Pinakothek, Munich; 'Deposition,' Moritz Chapel, Nuremberg; 'Madonna and Child,' National Gallery, London; 'Crucifixion,' Venice Academy.

Englehard, Friedrich Wilhelm, frēd'rĭʜ vil'hĕlm ĕng'ĕl-härt, German sculptor and painter: b. Grunhagen, Prussia, 1813; d. 1902. He studied at Hanover, at Copenhagen with Thorwaldsen, and at Munich with Schwanthaler. He executed many groups, single figures and genre pieces. Among his creations are: 'Love on a Swan'; 'Dancing Springtime'; 'Slinger with Dog'; 'Bacchus Conquering a Panther'; 'Cupid and Psyche'; the frieze of the 'Edda,' his chief work; 'A Child Fishing'; 'A Child Threading a Needle'; statue of 'St. Michael'; portrait medallion of Bismarck for the monument of Canossa, near Harzberg; 'Christ Blessing Little Children'; and the legendary characters of Germany, 'Odin,' 'Thor,' and the Valkyries.

Engelhardt, Johann Georg Veit, German theologian: b. Neustadt-an-der-Aisch, Bavaria, 1791; d. Erlangen 13 Sept. 1855. In 1822 he became professor of theology at Erlangen; during the years 1845, 1847, and 1848 was the representative of his university in the diet at Munich. His most celebrated works are a translation of the writings ascribed to Dionysius the Areopagite; 'Handbuch der Kirchengeschichte' (1834); 'Richard von St. Victor und Johannes Ruysbroek' (1838); 'Auslegung des speculativen Theils des Evangeliums Johannis durch einen deutschen mystischen Theologen' (1839); 'Dogmengeschichte' (1839).

Eng'elmann, George, American botanist: b. Frankfort-on-the-Main 2 Feb. 1809; d. St. Louis, Mo., 4 Feb. 1884. He studied at Heidelberg, Berlin, and Würzburg, and emigrated to the United States in 1832. In 1835 he began the practice of medicine at St. Louis, Mo. He early devoted his attention to botany, becoming the chief authority on the North American vine and cactus. He was the first president of the St. Louis Academy of Science, and his exhaustive botanical collection is in the Shaw Botanical Garden, St. Louis.

Engelmann, Johannes, yō-hän'nes ĕng'ĕl-män, Russian jurist: b. Mitau, Courland, 7 July 1832. Educated at the University of St. Petersburg, he became professor of Russian law at Dorpat 1860, retaining the chair for 39 years, and delivering his lectures in Russian instead of German after 1887. Among his works are 'Die Verjahrung nach russischem Privatrecht' (1867; in Russian, 1868); 'Die Zwangsvollstreckung auswärtiger richterlicher Urteile in Russland' (1884).

Engels, ĕng'ĕls, **Friedrich,** English Socialist: b. Bannen, Prussia, 28 Nov. 1820; d. London 5 Aug. 1895. He lived mainly at London after 1869. He was an intimate friend of Karl Marx (q.v.), and his most efficient helper in the work of organizing the Socialist movement. In 1870 Engels was corresponding secretary of the International Workingmen's Society for Belgium, Italy and Spain. With Marx he wrote the 'Communist Manifesto' (1847); he also wrote 'The Working Class in England in 1844' (new edition 1892); 'The Origin of the Family'; 'The Development of Socialism from Utopia to Science' (1894, a part of a large work left unfinished); and edited Marx's 'Capital.'

Engerth, ĕng'ert, **Eduard von,** Austrian painter: b. Pless, Silesia, 13 May 1818. He was a pupil of the Vienna Academy, taking the gold medal there in 1845. He became director of the Prague Academy 1854 and in 1855 professor at the Vienna Academy. He was appointed director of the Belvedere Gallery 1871 and director of the Academy 1874. He was made commander of the order of Francis Joseph 1867. Among his works are: 'Haman and Esther'; 'Ladislaus and Akus' (1844); 'Coronation of Rudolph I.'; 'Joseph Explaining the Dream' (1845); 'Seizure of King Manfred's Family' (1853), a masterpiece in the Vienna Museum; 'Victory of Prince Eugene at Zenta' (1865); 'Marriage of Figaro'; 'Fable of Orpheus' (1868); 'Coronation of Francis Joseph as King of Hungary' (1870); 'Death of Eurydice' (1877).

Enghien, Louis Antoine Henri de Bourbon, loo-ē än-twän ōn-rē de boor-bōn än-gàn, Duke of, French prince: b. Chantilly 2 Aug. 1772; d. Vincennes, France, 21 March 1804. He was the son of Louis Henry Joseph Condé, Duke of Bourbon. From 1796 to 1799 he commanded with distinguished merit the vanguard of Condé's army, which was disbanded at the Peace of Lunéville (1801). He then married and took up his residence at Ettenheim, in Baden. He was generally looked upon as the leader of the *émigrés,* and was suspected by the Bonapartists of complicity in the attempt of Cadoudal to assassinate the First Consul. The spies of Napoleon reported that Enghien was often absent for 10 or 12 days together from Ettenheim, and it was believed that on some of these occasions he had secretly visited Paris. Napoleon therefore invaded the duchy of Baden and the Duke of Enghien was seized 15 March 1804, conducted to Starsburg, and thence to the fortress of Vincennes, where he arrived on the evening of the 20th. That same night a court-martial was assembled, and the prisoner was, after a mock trial, in which no witnesses were examined, found guilty on various charges of treason. He requested an interview with Bonaparte, which was refused, and he was immediately led out to execution. He was shot between 4 and 5 o'clock in the morning in the ditch outside the walls, and his body was thrown, dressed as it was, into a grave dug, it is said, the day before. Napoleon and the other chief actors in the tragedy took every pains to justify their conduct, or to throw the chief blame upon others' shoulders, and it is believed by some that the First Consul found himself in the position of a leader whose subordinates are only too ready to rush extreme measures on the least hint from their master.

Enghien, or **Enguien,** Belgium, (1) Town in Hainault, about 19 miles southwest of Brussels. One of the chief occupations is lace making. (2) A watering place a short distance north of Paris.

Engine. A motor or prime mover which is capable of absorbing the inherent forces of material substances such as steam, gas, and water through the medium of heat and pressure, and then converting those forces into mechanical energy in the form of motion, which may be utilized for doing mechanical work, thus distinguishing it from a "machine," which can receive motion only from a motor or engine external to itself.

The various forms of engines may be classified into two general groups — heat engines and hydraulic engines, according to the manner in which they convert the natural forces into mechanical energy, power, or work.

All heat engines act through the medium of a working substance which absorbs heat, converts a portion of that heat into mechanical energy, which is represented by the work performed by the engine, and rejects the remaining portion of the heat, still in the form of heat. The working substance may be a gas, a liquid, or a solid, and incidentally affords a basis upon which the various practically successful forms of heat engines may be conveniently grouped into three general classes — steam engines, gas and oil engines, and steam turbines.

Steam Engines.— In all forms of actual steam engines, the working substance is saturated steam, a fluid consisting of a mixture of water and steam in varying proportions, the expansive energy of which is utilized to drive or impart motion to a piston working within a cylinder.

They may be classified as follows: (1) according to the manner in which the steam is utilized; (2) according to the mechanical arrangement of their parts; and (3) according to the purposes for which they are used.

The first class includes the high-speed and low-speed engines; the single-acting and double-acting engines; the direct-acting and indirect-acting engines; the expansive working and non-expansive working engines; the condensing and noncondensing engines; and the simple engines, compound engines, and multiple-expansion engines, which may be briefly described as follows:

High-Speed Engine.— One in which the piston speed exceeds 900 feet per minute. It possesses the advantages of small dimensions and small weight for a given power, and on account of the frequency of its strokes, is capable of meeting variations in loading more quickly than a low-speed engine. Its disadvantages consist in the greater waste of steam, the greater wear, and the increased danger of the heating of the moving parts. Also, the higher cost of construction and operation.

Low-Speed Engine.— One in which the piston speed is less than 600 feet per minute.

Single-Acting Engine.— One in which the pressure of the steam is exerted only on one side or the under side of the piston, which is pressed down again by the pressure of the atmosphere on the other side against the vacuum produced by the condensation of the spent steam. They were formerly used chiefly for pumping purposes, and in connection with steam hammers, but are now practically out of date.

Double-Acting Engine.— One in which the steam acts alternately on both sides of the piston, either against the pressure of the air, or against the vacuum of the condenser. Originally, all engines were made single-acting, but all modern engines are made double-acting.

Direct-Acting Engine.— One in which the action of the piston is transmitted directly to the crank-shaft. Nearly all engines are direct-acting engines.

Indirect-Acting Engine.— One in which the motion of the piston is communicated to the crank-shaft by means of intermediate levers. In the beam-engine, the connection between the piston and the connecting rods consists of a beam, the oscillating point of which is placed midway between the two rods. They are chiefly employed for pumping purposes, and for driving paddle-wheel steamers. Other than in this limited field, they are becoming practically obsolete.

Expansive Working Engine.— An engine is worked expansively when the steam, instead of being admitted at full pressure into the cylinder until the termination of the stroke, is cut off at some fractional part of the stroke and thus caused to do work simply by its own expansion. The steam may be expanded in one or more cylinders. The amount of steam consumed is low as compared to the amount of work done. It is universally used where circumstances will permit, on account of its greater economy as compared to the engines of the nonexpansive working type.

Nonexpansive Working Engine — An engine in which the steam is allowed to enter the cylinder at boiler pressure, and is maintained at that pressure behind the piston during the whole of the stroke. The amount of steam consumed is disproportionately high as compared to the work done. It is never used except in cases where circumstances will not permit of the use of an expansive working engine.

Condensing Engine.— One in which the spent steam in the cylinder is exhausted into a vacuum and condensed into water, thus obliterating the back pressure of the atmosphere, and consequently effecting a gain of pressure equivalent to 14.7 pounds per square inch, in the effective working pressure of the steam.

Noncondensing Engine — One in which the spent steam in the cylinder is exhausted into the air at atmospheric pressure, thus entailing the work of forcing the piston against a back pressure of 14.7 pounds per square inch, at the expense of the effective working pressure of the steam.

Simple Engine.— One in which the steam after having forced the piston through its stroke is exhausted into the air, or into a vacuum or condenser.

Compound Engine.— An engine with two or more cylinders in which the steam after having expanded and performed its work in one cylinder passes into the next cylinder, of larger size, and continues to expand and perform work. The different types of compound engines are distinguished by the number of cylinders employed for the expansive working of the steam, and are designated as the two-cylinder engine, the three-cylinder or triple-expansion engine, and the four-cylinder or quadruple-expansion engine. The cylinders are usually arranged side by side or parallel with each other. Sometimes, as in the case of the « tandem-compound,» they are placed « in line » one behind the other, and also vertically one above the other as in the case of the « steeple-compound.» In a « cross-compound,» the cylinders are placed side by side and parallel to each other, but sufficiently far apart to allow space for a fly-wheel between them. Up to the present time, the quadruple-expansion engine appears to be the limit beyond which the number of expansions have not been carried with success. The great practical advantage of the multiple expansion engines lies in their high steam economy.

The second class of steam engines includes the various types of reciprocating engines which are more definitely designated as horizontal engines, vertical engines, and inclined engines, according to the position of the axis of the piston, and various forms of direct-acting and indirect-acting engines, such as beam engines, oscillating engines, trunk engines, back-acting engines, and various forms of rotary engines.

The third-class includes the various forms of marine engines, stationary or land engines, locomotive engines, and a great variety of portable engines. The engines included in these two classes may be briefly described as follows:

Reciprocating Engine.— One in which the piston moves backward and forward alternately, in a right line. Almost all heat engines are of this type.

Horizontal Engine.— One in which the axis of the cylinder and piston rod is horizontal.

Vertical Engine.— One in which the axis of the cylinder and piston rod is vertical. Vertical engines are made in a great variety of forms, and are usually arranged with the cylinders uppermost. Very few of them are constructed with the cylinders lowermost, and those are only of the smallest sizes. The principal advantages of the vertical engines consist in the small space required for their foundations, and the uniformity of wear on the cylinders, pistons, and rods. The type includes many forms of steam hammers, launch engines, screw engines, and inverted cylinder engines.

Inverted Cylinder Engine.— A vertical engine in which the cylinder is inverted or placed above the piston rod, connecting rod, and crank-shaft. It is typical of the marine engines employed to drive screw propellers.

Inclined Engine or Inclined Cylinder Engine. — A form of marine engine in which the cylinders are inclined toward each other at an angle of about 120 degrees, and make a triangle with the base. They are connected by cranks to a common crank-shaft.

Beam Engine.— An indirect-acting engine in which the piston rod is connected to the connecting rods by means of a lever in the form of a beam. It is more fully described under the term Indirect-Acting Engine.

Oscillating Engine.— A marine engine of the direct-acting type in which the cylinders are suspended upon hollow trunnions and oscillate thereon, thus allowing the motion of the piston rods to accommodate itself to that of the crank at all parts of the revolution. It occupies but little space, and is peculiarly adapted for paddle-wheel steamers. For screw propulsion, it has been entirely supplanted by the various forms of multiple-expansion engines of the inverted cylinder type.

Trunk Engine.— An interesting though practically obsolete form of marine engine formerly used on war vessels. The aim of its design is compactness of arrangement, so as to place all of its working parts below the waterline, thus protecting them from the enemy's shot. Its distinguishing feature is a hollow, trunk-shaped piston rod which passes through both ends of the cylinder and is encircled in the middle by the piston head. The connecting rod is attached to the interior of the piston rod, thus saving the length of the piston rod in all of the vertical dimensions of the engine. Its chief defect consists in its low steam economy, due to the great loss of heat by radiation from the large conducting surfaces of the hollow piston rod which are exposed to the air.

Bogie Engine.— A locomotive provided with a bogie or swivelling framework which carries the axle of the main driving wheels, and enables the main framing to accommodate itself to curves of short radii. In the single bogie, the main driving wheels are the bogies; in the double bogie, both the main driving wheels and the back driving or trailing wheels are bogies. A bogie truck is a short four-wheeled truck pivoted at its centre to the main frame of the engine, and enables the engine to run around sharp curves.

Corliss Engine.— A very economical type of engine in which the valves are controlled automatically from the governor, and the steam supply proportioned to the requirements of the engine at each moment during its working stroke. The valve forms a segment of a circle and revolves through an arc of a circle, and alternately covers and uncovers the steam port. It is operated by a rod from a wrist plate, but is disconnected at every stroke of the engine, and the supply valve closed instantaneously by means of a dash-piston and spring.

Cornish Engine.—A standard type of pumping engine, originally of the single-acting type. At the present time it appears in two forms — the beam engines and the direct-acting engines. The valves of a Cornish engine are operated by a special device called a cataract consisting of a weighted piston which works in a cylinder provided with a large inlet valve and a small discharge valve. The working stroke of the pump lifts the weighted piston and draws the water into the cylinder through the former, and the return stroke discharges it through the latter, and at the same time actuates the valves of the steam cylinder of the pump so as to cause another working stroke.

Marine Engine.— Any form of engine used for propelling a vessel. They are usually of the compound or multiple-expansion type.

Stationary Engine.— An engine on fixed foundations, as distinguished from the locomotive, portable, and marine engines.

Locomotive Engine.— A high pressure steam engine and multitibular complete, mounted on a carriage, and provided with suitable wheels to enable it to draw loaded cars upon a permanent way or railway track.

Portable Engine.— An engine of the locomotive type, mounted on a carriage which permits of its being moved from place to place for use in connection with work of a temporary character. Portable engines are extensively used for agricultural purposes, and for general traction purposes on ordinary highways.

Gas and Oil Engines.— These classes of heat engines are commonly designated as internal combustion engines for the purpose of distinguishing them from the various more or less impracticable forms of hot air engines in which the working substance consists of air alone, which is heated from an external furnace, the heat being conducted through the walls of the containing vessel.

In the gas engines, the working substance or charge is a mixture of coal gas and air, explosive in character, which is introduced into the working cylinder where it is compressed by the action of the piston, and then ignited and exploded by a special device. The energy developed by the explosion is utilized to actuate the piston or do mechanical work.

This method of heating the working substance is called the gas engine method. It is one feature possessed in common by all gas engines irrespective of variations in form, or of working cycles, and serves to distinguish them from all other forms of heat engines.

The various types of gas engines may be conveniently divided into three general classes, according to their mode of operation as follows: (1) Those in which a specified amount or constant volume of gas is drawn into the cylinder at atmospheric pressure or without compression, and then ignited, as in the case of the Lenoir, Hugon, and the Otto-Langen engines, which were quite successful for powers under one-horse power, but are practically obsolete; (2) those in which the working substance is first compressed in an auxiliary cylinder and then admitted to the working cylinder and ignited, as in the case of the Brayton engine, which although the most successful engine of this class is also practically obsolete; and (3) those in which a specified amount or constant volume of gas is admitted to the working cylinder where it is compressed by the piston and then ignited, as in the case of the Otto engine, and in, by far, the greater number of other gas engines in successful use at the present time.

Gas engines are also designated as two-cycle, four-cycle, and six-cycle engines, according to the number of distinct operations in their working cycles. The six-cycle engines were of the scavenging type, but were not successful, and are obsolete. The four-cycle engines represent the application of the Beau de Rochas or Otto cycle, and constitute the most successful type developed up to the present time. The two-cycle engines are as yet in a comparatively experimental state, but possess great possibilities of successful development, and may eventually supplant all the other forms.

Up to within the last few years, the gas engines were rarely made in sizes capable of developing an amount of power equivalent to 50, 75, or 100 horse-power, and rivalled steam engines of equal capacity only in special and limited fields of application; but now, since the introduction of the various gas producer systems, gas engines developing 4,000 horse-power are in successful use, and others capable of developing as high as 6,000 horse-power are in the process of construction.

The oil engine differs from the gas engine principally in the character of the charge, which consists of a mixture of vaporized petroleum, gasoline, or paraffin oil and air. They may be conveniently classified, (1) according to the method employed to vaporize the oil; or (2) according to the method employed to ignite the charge.

The first class includes those in which the oil is subjected to a spraying operation before being vaporized; those in which the oil is injected into and vaporized within the cylinder; and those in which the oil is vaporized by a special apparatus outside the cylinder and then admitted into the cylinder in the form of a vapor.

The second class includes those in which the charge is ignited by means of an electric spark; those in which the charge is ignited by an incandescent tube; and those in which the charge is ignited by the heat of the internal surfaces of the combustion chamber.

Steam Turbines comprise a class of heat engines in which the kinetic energy of expanding steam is utilized to drive a wheel and thus convert the natural heat energy of steam directly into mechanical energy in the form of rotary motion. The principal forms are the Parsons, De Laval, Seger, and Dow turbines, and their chief field of application and development appears to be in the marine service. Noteworthy examples of their latest applications are those of the Cunard Line Passenger Steamship «Carmania,» and the battleship «Dreadnaught,» of the British Royal Navy, the largest warship in the world built up to date.

Hydraulic Engines.—Mechanical power is obtained from flowing water by its weight, pressure, or impact, utilized in various forms of water wheels, turbines, hydraulic rams, and water pressure engines. In the water pressure engine the pressure of the water only is utilized to drive a piston in a cylinder. In some forms the action of the piston is reciprocating, and in others rotary. In all of them the actual amount of pressure expended is only that which is needed to impart motion to the fluid to follow the piston and escape from the cylinder, and, therefore, the greatest efficiency is obtained by making the piston as small as practicable and using a large pressure. The majority of them are of the reciprocating, low-speed type, and are particularly useful as secondary motors for operating the opening machinery of various forms of swing, draw, and lifting or rolling bridges, and in connection with cranes and various forms of hydraulic lifts.

For further detailed information relative to the construction, operation, and application of the various forms of engines, consult the articles under the titles: GAS ENGINES; LOCOMOTIVE; LOCOMOTIVE, DESIGN AND CONSTRUCTION OF THE MODERN; LOCOMOTIVE ENGINE; PUMPS AND PUMPING MACHINERY; ROTARY STEAM ENGINE; TRACTION ENGINES; TURBINES; WATER MOTOR; AND WATER WHEELS, in this Encyclopedia.

WILLIAM MOREY, JR., C. E.,
Consulting Civil and Mechanical Engineer, New York City.

Engine, Testing of. Engines are tested in order to determine the economy with which they produce a given amount of power. The economy of steam engines, as usually determined, relates to the weight of steam consumed, or to the quantity of coal used in making the steam, or to the number of heat units supplied; while in the case of an internal combustion engine, it relates to the amount of gas, gasoline, oil, alcohol, or other fuel burned. Also, if the latter operate on producer gas, the determination of economy involves the amount of coal burned in the gas producer.

Factory tests are generally limited to the performance of individual engines, to determine the set of the governor relative to the proper speed, and to ascertain if the valves are set and operate properly. In the case of gas engines, the factory test is extended to cover the correct timing of the igniter, and to determine the correct compression.

In its broadest sense, however, testing is a form of scientific investigation conducted for the purpose of securing practical results which are very important not only to the manufacturer, but also to the owner of the engine who has to pay the expense of its operation, and to those who require information showing the capabilities of the machines for the purpose of advertising and trade.

As an engine test involves the determination of two elementary quantities,—(1) the amount of fuel consumed, and (2) the amount of power developed,—it is necessary that these two factors should be represented by units of measurement which are susceptible of universal application.

Standard Unit of Fuel.—The most satisfactory unit for expressions of economy based on the amount of fuel consumed, is the British Thermal Unit (B.T.U.), which is the quantity of heat required to raise one pound of water one degree Fahrenheit at or about 39.1° Fahr. According to Joule, it is equivalent to 778 foot-pounds of mechanical energy.

A convenient and useful subsidiary standard is that based on a «standard coal» unit, the term «standard coal» defining a coal which imparts to steam 10,000 B.T.U.'s for each pound of dry coal consumed. It is a coal which has a calorific value of 12,500 B.T.U.'s, equivalent to an efficiency of 80 per cent. when used in a «standard boiler.»

Standard Unit of Power.—The unit of mechanical power which most satisfactorily expresses the power developed by an engine, is the «horsepower,» which represents an energy of 33,000 foot-pounds per minute, equivalent to 2,545 B.T.U.'s per hour.

Standard of Engine Economy.—Employing the given standard units of fuel and power, the expressions of engine economy which are best adapted to meet all conditions of service, and for all classes of heat engine, are those represented by the «indicated» horsepower based on the number of B.T.U.'s consumed per hour.

Such an expression is commonly called a horsepower-hour, and represents a heat energy of 1,980,000 foot-pounds converted into mechanical power or work by the consumption of 2,545 B.T.U.'s per hour.

Rules for Conducting a Test.—All tests should be conducted systematically under a set of standard rules, clearly defining the character of the data to be obtained and the methods which should be employed for their determination. A set of such rules may be briefly defined as follows:

1. *Object of the Test.*—At the beginning, the specific object of the test should be ascertained. It may relate to the determination of highest economy obtainable; the economy under ordinary working conditions and the existing defects; the performance under special conditions; the effect of changes in existing conditions; or the fulfillment of a contract guarantee; and the preparations for the test should be made accordingly. These preparations will necessarily depend largely upon the good sense, judgment, and ingenuity of the engineer making the test.

2. *Condition of the Engine.*—The engine should be carefully examined and its general condition noted, especially any points of design, construction, or operation which bear upon the object of the test. Special examination should be made of all valves, by inspecting their seats and bearing surfaces, and great care taken to ascertain, in the case of a gas engine, that the piston rings work freely in their grooves and are perfectly gas-tight.

3. *Dimensions.* — The cylinder dimensions should be taken whether they are already known or not, the measurements being made when they are hot and in working order. When practicable, the clearance volume or compression space of the cylinder should be measured by filling it with water previously measured, the proper correction being made for temperature.

4. *Fuel.*—When the test involves the complete plant—in the case of a steam engine including the boilers, and in the case of a gas engine including the gas producer plant,—the class, name of mine, size, moisture, should be stated in the report,—and the quality of the coal used should be of some recognized standard. This is desirable for purposes of comparison. In the case of an internal combustion engine, if the test is made to determine the maximum efficiency, the gas, oil, or other fuel used, should be the best obtainable, or one that possesses the highest calorific value.

5. *Measurement of Fuel.*—The methods of determining the amount of fuel consumed depend upon the character of the fuel used. If it be coal furnished to the furnace of a boiler, or to a gas producer, the amount consumed during a period not less than 24 hours should be carefully measured by weight. If it be oil, gasoline, distillate, alcohol, etc., it can be drawn from a tank, which can be refilled to the original level at the end of the test, and the amount required for this purpose weighed; or in the case of a small engine, it can be drawn from a properly calibrated vertical pipe. When gas is used, it should be measured by a suitable gas meter, and gas bags should be placed between the meter and the engine to keep the pressure as constant as possible. The pressure and temperature of the gas, and the barometric pressure and temperature of the air, should be measured, and in determining the quantity of the gas supplied, as given by the reading of the meter, the temperature and pressure of the gas should be taken into account.

6. *Measurement of Heat Units Consumed.*—The number of heat units consumed by the engine can be found by multiplying the number of pounds of coal or oil, or the cubic feet of gas supplied, by the total heat of combustion of the fuel as determined by a calorimeter, or from the results of a chemical analysis. In determining the total heat of combustion, usually, no deduction is made for the latent heat of the vapor of water in the products of combustion, therefore, for purposes of comparison care should be taken to state whether the higher or the lower value has been used in the determination.

The Mahler calorimeter is the most suitable for determining the heat of combustion of solid fuels and oils, and the Junker calorimeter for gases.

7. *Instruments and Their Calibration.*—All instruments and apparatus used in the tests should be calibrated, and their accuracy verified by comparison with recognized standards. All such as are liable to undergo changes, or become broken during the progress of a test, especially gauges, indicator springs, and thermometers, should be calibrated both before and after the test.

Gauges.—For measuring pressures above that of the atmosphere, the most convenient and reliable standard is the dead-weight testing apparatus consisting of a cylinder having a close-fitting vertical piston working in oil or glycerine, by the medium of which the pressure is transmitted to the gauge. The piston is surmounted by a circular stand on which weights may be placed so as to secure any desired pressure. The total weight, in pounds, on the piston, divided by the area of the piston, in square inches, gives the pressure in pounds per square inch.

The mercury column is another reliable standard of comparison for pressures, but when it is used care should be taken to see that it is properly graduated with reference to the ever varying zero point; that the mercury is pure, and that the proper correction is made for any difference of temperature that may exist at the time of using, and the temperature at which the instrument was graduated.

For pressures below that of the atmosphere, the use of an air pump or some other means of producing a vacuum is required. The apparatus must be referred to a mercury gauge, which may consist of an U-shaped tube about 30 inches in length, with both arms properly filled with mercury.

Thermometers.—Standard thermometers are those which read 212° Fahr. in steam escaping from boiling water at the normal barometric pressure of the atmosphere (29.92 inches) when the whole stem up to the 212° point is surrounded by the steam; and which read 32° Fahr. in melting ice, when the stem is completely immersed to the 32° point; and which are calibrated for points between and beyond these two points of reference.

For temperatures between 212° and 400° Fahr., the thermometers should be compared with the temperatures given in Regnault's Steam Tables, by placing it in a mercury well surrounded by saturated steam under sufficient pressure to give the desired temperature.

For higher temperatures, such as those occurring in gas-engine practice, which often exceed 2,000° Fahr., some form of pyrometer or calorimeter should be used. That of Le Chatelier, which makes use of the thermocouple, has been successfully used for accurately measuring temperatures over 2,500° Fahr.

Indicator Springs.—For gas engine indicating, the indicator springs used should be much stiffer and stronger than those used for steam-engine work, so as to enable them to withstand the higher and more suddenly developed pressure. When indicator springs are calibrated, the temperature of the indicator should be as nearly as possible the same as that which exists during the test. An indicator may be conveniently heated by subjecting it to steam pressure immediately before calibration, and the actual work of calibration then performed by the use of compressed air or compressed carbonic acid gas. The calibration may be made under a constant pressure, or more satisfactorily by covering the whole range of pressures through which the indicator acts, by gradually increasing the pressure from the lowest to the highest point, and then by gradually reducing it from the highest to the lowest point, and a mean of the results taken for at least five points—two for the pressures corresponding to the maximum and minimum pressures, and three for equally distant intermediate points. These values should be compared with a dead-weight-testing apparatus, a mercury column, or a steam gauge, compared with either of the two first-named standards, and the correct scale of the spring used for calculating the mean effective pressure from the indicator diagrams taken during the test should be the average based on this calibration.

Gas Meters.—A meter used for measuring the gas supplied to a gas engine, should be calibrated by comparing its readings with the displacement of a gasometer of known volume; with a standard gas meter of known error; or by passing air through the meter from a tank containing air under pressure. In the latter case, the pressure and temperature of the air in the tank, both at the tank and the meter, should be observed at uniform intervals of time during the work of calibration; and the amount of air passing through the meter calculated from the volume of the tank and the observed temperatures and pressures.

The volume of the gas thus ascertained should be reduced to the equivalent volume at a given temperature and atmospheric pressure, corrected for the effect of moisture in the gas, which is usually at or near the point of saturation. For gas-engine work, a convenient standard is the equivalent volume of the gas when saturated with moisture at normal atmospheric pressure at a temperature of 60° Fahr. A volume of moist gas at any other temperature may be reduced to this standard by being multiplied by the factor

$$\frac{459.4+60}{459.4+t} \times \frac{b-(29.92-s)}{29.4},$$

in which b represents the reading of the barometer in inches at 32° Fahr.; t, the temperature of the gas at the meter in degrees Fahr.; and s, the vacuum in inches of mercury corresponding to the temperature of t given in the steam tables.

8. *Duration of a Test.*—The length of time devoted to a test will depend largely upon its character and the purpose for which it is made. For determining the working economy, the time allowed should be equal to the number of hours per day during which the engine is really operated. In the case of a gas engine using producer gas, the time should be sufficient to determine the amount of coal used in the gas producer. It should never be less than 24 hours, and usually, it should extend over several days.

9. *Commencement of a Test.*—If the test is to determine the performance of an engine under working conditions, it should begin at the time the engine is started, and the observations continued until it shuts down for the day. If the test is for determining the maximum economy of the engine; at first, it should be run a sufficient length of time to make all conditions normal and constant, then the observations may be commenced and continued for the allotted time.

10. *Measurement of Water.*—In the case of a steam engine this relates to the feed water or steam consumption. The usual method is to measure all the feed water supplied to the boilers, and deduct therefrom all the water discharged by separators and drips, and the water and steam lost by leakage from the boiler and its main and branch pipe connections with the engine. Where the engine exhausts into a surface condenser, the steam consumption can be measured by measuring the quantity of water discharged by the air pump, and adding thereto the steam used by jackets, reheaters, and auxiliaries as determined independently. In measuring the water, it should be carried through a tank resting on the platform of a suitably arranged weighing scales, and the water subsequently emptied into a reservoir beneath, from which the pump is supplied.

For measuring small quantities of water, about 6,000 pounds per hour, the most convenient apparatus consists of a small hogshead connected to the suction pipe of the pump or injector, and an ordinary oil barrel placed on a platform scale. The barrel is filled by means of a cold-water pipe leading from the source of supply. For pressure not less than 25 pounds per square inch, this pipe should have an internal diameter of 1½ inches. The outlet valve of the barrel is attached to the side, near the bottom, and should be at least 2½ inches in diameter, so as to permit of quick emptying.

Where larger quantities of water have to be measured, the barrel can be replaced by a hogshead and two hogsheads can be joined together for the lower reservoir. With this arrangement, when the weighing hogshead is supplied through a 2½-inch valve under 25 pounds of pressure, and emptied through a five-inch valve, the capacity attained is 15,000 pounds of water per hour.

For the measurement of very large quantities, or in some cases, very small quantities, the orifice method gives the most satisfactory results, and when applied, the average head of water on the orifice must be ascertained, and the discharge of the orifice should be calibrated under the conditions of use.

In the case of an internal combustion engine, the measurements of water relate to that supplied to the water-jacket provided for cooling the temperature of the cylinder. The measurements may be made by the methods already described, but care should be taken, in cases where the temperature exceeds 212° Fahr., to first cool the water by discharging it into a tank of cold water previously weighed, or by passing it through a coil of pipe immersed in running cold water, so as to prevent the loss of evaporation which takes place when hot water is discharged into the open air.

11. *Determination of Speed.*—The speed of the engine or the number of revolutions of the crank shaft per minute can be determined by counting the number of revolutions in one minute with the eye fixed on the second hand of a timepiece, or by the use of some form of mechanical counter such as a tachometer, or continuous recording engine register. The use of such instruments is imperative when the speed exceeds 250 revolutions per minute.

In the case of internal combustion engines governed by the hit-or-miss method, the number of explosions per minute should be ascertained, when the engine is running under nearly maximum load, by counting the number of times the action of the governor causes a miss in the explosions.

The determination of variation of speed during a single revolution on the effect of fluctuations due to sudden changes of load, should be made especially in the case of engines employed to drive electric generators used for lighting purposes.

12. *Indicator Diagrams.*—From the indicator diagrams taken during the test for the computation of the mean effective pressure, etc., sample diagrams nearest to the mean should be appended to the report.

The mean effective pressure (M.E.P.) is obtained as follows: Measure the diagram with a planimeter and divide the area, in square inches, thus obtained by the length of the diagram in inches to obtain the mean height or mean ordinate of the diagram. Multiply the mean ordinate by the scale of the indicator spring and the product will be the mean effective pressure desired. In the absence of a planimeter, the diagram can be divided by ten ordinates and their mean length taken for that of the mean ordinate. If the indicator is specially designed for indicating internal combustion engines, the mean ordinate should be multiplied by twice the scale of the spring, unless the scale has been expressly marked for the reduced piston.

In the case of internal combustion engines, when indicator diagrams are not obtainable and the compression pressure is known, the mean effective pressure may be determined approximately as follows: For example, in gas engines the compression pressure ranges from 70 to 90 pounds per square inch, and the maximum pressure developed by the explosions is about 3.5 times the compression pressure. Therefore, if p represents the compression pressure, then for compressions of 100 pounds per square inch or less, $\text{M.E.P.} = 2p - 0.01p^2$; thus, if $p = 70$ pounds per square inch, $\text{M.E.P.} = 140 - 49 = 91$ pounds per square inch.

In the case of a steam engine, the steam accounted for by the indicator diagram may be calculated by means of the formula

$$M = \frac{13750}{\text{M.E.P.}} \left((C+E) \times Wc - (H+E) \times Wh \right),$$

which will give the weight in pounds per indicated horsepower per hour. M.E.P. represents the mean effective pressure, which in the case of a multiple-expansion engine is the combined mean effective pressure referred to the cylinder in question. For example: In the case of a compound engine, the combined mean effective pressure for the high pressure cylinder consists of two items: (1) the mean effective pressure of the high pressure cylinder, and (2) the mean effective pressure of the low pressure cylinder multiplied by the ratio of the piston displacement of the low pressure cylinder to that of the high pressure cylinder. The sum of these two items is the combined mean effective pressure for the high pressure cylinder.

Similarly the combined mean effective pressure for the low pressure cylinder consists of (1) the mean effective pressure of the low pressure cylinder, and (2) the mean effective pressure of the high pressure cylinder divided by the ratio already stated. The sum of the two items is the combined mean effective pressure of the low pressure cylinder.

In the given formula, C represents the proportion of the piston stroke completed at points on the expansion line of the diagram near the actual cut-off or release; H the proportion of compression; and E the proportion of clearance; all of which are determinable from the indicator diagram. Wc represents the weight of one cubic foot of steam at the cut-off or release pressure; and Wh the weight of one cubic foot of steam at the compression pressure.

13. *Standards of Economy and Efficiency.*—The standard expression for engine economy, as already stated, is the hourly consumption of heat units divided by the indicated horsepower or the brake horsepower. The standard expression for efficiency is the thermal efficiency ratio, or the proportion which the heat equivalent of the power developed bears to the total amount of heat actually consumed, as determined by test. One horsepower-hour represents the consumption of 2,545, B.T.U.'s per hour, therefore,

$$\frac{2{,}545}{\text{B.T.U.'s per horsepower per hour}},$$

expresses the thermal efficiency ratio.

In comparing the standard for internal combustion engines with that for steam engines, it must be noted that the former usually covers the losses due to combustion, but the latter does not, and therefore, in order to make a direct comparison between the two classes of engines as complete horsepower plants, the losses in generating the working agent must be considered in both cases not only on the basis of the fuel used, but on the basis of equivalent fuel used in each case. In comparing a gas engine plant using producer gas, with a steam plant, the producer should be included in the former, and then the fuel consumption, represented by the weight of coal in both cases, may be directly compared.

14. *Heat Analysis.*—For scientific purposes, a heat analysis of the indicator diagram, in the case of a steam engine, and a heat balance in the case of an internal combustion engine, should be made, showing the manner in which the total heat of combustion is expended in working the engine.

In the case of a steam engine, the analysis shows the interchange of heat from steam to cylinder walls, etc. For example: the amount of heat supplied to the engine in a given time is represented by the number of pounds of steam supplied multiplied by the total heat of one pound of steam. A portion of this heat is used in the jacket, if one be employed, and the remainder passes through the cylinder. The heat entering the jacket is lost partly by radiation from the outside surface, and the remainder enters the walls of the cylinder and is absorbed by the steam within it. The cycle of operations within the cylinder consists of the following phases: (1) A portion of the entering heat is transferred into a small portion of the thickness of the cylinder walls, and heats them to the temperature of the entering steam. This transference of heat is more active during the period of admission and up to the point of cut-off than during any other part of the cycle. (2) Beyond the point of cut-off, the transference of heat continues until the lower pressure due to expansion causes the temperature of the steam to fall below that of the interior surfaces of the cylinder last uncovered. At this point the interchange of heat is reversed, the metal giving up heat to the steam, and causing the re-evaporation of the particles of water condensed on the surface of the cylinder walls and piston. The radiation of heat from the small thicknesses of the interior walls which were heated during admission to the temperature of the entering steam, commences after cut-off or after the pressure begins to lower by expansion, and continues to the end of the stroke.

A portion of the heat is also expended in the performance of work, and a loss of heat is sustained by radiation from those portions of the cylinder not protected by the jacket. The amount of heat remaining after the steam has passed through these operations is that which is rejected by it through the exhaust valve to the atmosphere or to the condenser.

In the case of an internal combustion engine, the total heat of combustion expended in the working of the engine may be divided into three parts: (1) Heat converted into work and represented by indicated or brake horsepower. (2) Heat carried away by the cooling water circulated through the water jacket. (3) The heat lost in the exhaust gases, and through incomplete combustion and radiation.

15. *Heat Converted into Indicated or Brake Horsepower.*—The number of foot-pounds of work done by one pound or one cubic foot of fuel divided by 778, the mechanical equivalent of one British Thermal Unit, will give the number of heat units desired.

16. *Heat Carried Away by the Jacket Water.*—This is determined by measuring the quantity of cooling water passed through the water jacket equivalent to one pound or one cubic foot of fuel consumed, and calculating the amount of heat rejected by multiplying that quantity by the difference of the temperature of the water entering and leaving the jacket.

17. *Heat Rejected in the Exhaust Gases, or Total Heat Unused.*—The sum of the heat converted into brake horsepower and the heat carried away by the jacket water, subtracted from the total heat supplied, will give the total heat rejected or unused.

In order to determine the cost of each horsepower hour in thermal units, the gas consumed and the air supplied should be reduced to the conditions of temperature and pressure corresponding to some adopted standard. This may be done as stated under gas meters in rule 7, or more conveniently by the formula

$$v = \frac{t}{p} \times \frac{v^1 p^1}{t^1},$$

in which v = volume of gas reduced to standard; $t = 461 + 60 = 521°$ Fahr., absolute standard temperature; $p = 29.92$ inches of mercury; v^1 = volume of gas registered by meter; p^1 = pressure of gas at meter measured by manometer in inches of water; t^1 absolute temperature of gas.

Since t and p are constants

$$v = 18.00\,\frac{v^1 p^1}{t^1},$$

and as p^1 and t^1 are practically constant during a given test, $v = E\,v^1$, in which

$$E = 18.00\,\frac{p^1}{t^1}$$

and p^1 = height of barometer + (0.073 × reading of manometer); and t^1 = temperature of gas at meter + 461.

For example: Assume the height of the barometer as 29.40 inches; the reading of the manometer as 6 inches; the temperature of the gas 80° Fahr.; and the volume of the gas registered by the meter 350 cubic feet; then for determining (v) the equivalent volume of gas for standard conditions =

$$p^1 = 29.40 + (0.073 \times 6) = 29.84;$$
$$t^1 = 80 + 461 = 541;$$
$$E = \frac{18.00 \times 29.84}{541} = 0.976;$$

then $v = 0.976 \times 350 = 341.6$ cubic feet.

The air supplied should be metered and reduced to standard conditions in the same manner.

If the rate method is employed to ascertain the amount of gas consumed, the number of cubic feet for a ten-minute interval may be found by dividing the number of cubic feet registered by one revolution of the small dial by the time in seconds elapsed at the completion of that revolution and multiplying the result by 6,000.

18. *Indicated Horsepower* (I.H.P.).—This factor, is expressed by the formula—

$$\text{I.H.P.} = \frac{P \times L \times A \times N}{33{,}000},$$

in which P is the mean effective pressure in pounds per square inch; L the length of the piston stroke in feet; A the area of the piston in square inches; and N the number of revolutions of the engine crank shaft per minute.

$$\frac{A \times L}{33{,}000},$$

is constant for a given engine, and in the case of an internal combustion engine, N is the number of explosions per minute.

19. *Brake Horsepower* (B.H.P.).—When this factor is determined by the use of some form of dynamometer, such as the Prony brake, it may be readily computed from the formula—

$$\text{B.H.P.} = \frac{W \times N \times L \times C}{33{,}000},$$

in which W is the net weight in pounds on the scales; N the number of revolutions per minute; L the length of the lever arm, from the center of the braked wheel to the knife-edge of the brake, or the radius of the braked wheel if a rope brake is used; and C the circumference of the braked wheel.

$$\frac{C \times L}{33{,}000},$$

is constant for a given Prony brake, therefore, if L be made 5¼ feet, this constant becomes 0.001, and gives the simple and very convenient expression—

$$\text{B.H.P.} = \frac{N \times W}{1000}.$$

20. *Total B.T.U.'s Per Hour.*—The total amount of gas consumed, in cubic feet, multiplied by its calorific value.

B.T.U.'s Per Brake Horsepower-Hour.—The total B.T.U.'s per hour divided by the brake horsepower.

B.T.U.'s Per Indicated Horsepower-Hour.—The total B.T.U.'s per hour divided by the indicated horsepower.

Friction Horsepower.—The difference between the indicated horsepower and the brake horsepower.

Thermal Efficiency.—The ratio of 2,545 B.T.U.'s to the B.T.U.'s per horsepower hour.

Mechanical Efficiency.—The ratio of the brake horsepower to the indicated horsepower.

WILLIAM MOREY, JR., C. E.,
Consulting Civil and Mechanical Engineer, New York.

Engineer Corps, a branch of the service of the United States Navy; and of those of other countries. The first step toward the organization of an engineer corps in the United States Navy was taken on 2 July 1836, when C. H. Haswell (q.v.) was appointed chief engineer of the *Fulton;* it was not, however, until 31 Aug. 1842 that Congress passed an act providing for a regular corps, under which act chief engineers were "commissioned" and assistants "warranted." On 3 March 1845 Congress passed an act whereby the power of appointing engineer officers was transferred from the Secretary of the Navy to the President "by and with the advice and consent of the Senate." With the growth of the navy the corps gradually increased till at the time of the Civil War there were 474 regulars and 1803 volunteers.

A course of instruction for cadet engineers was established at the Naval Academy by act of Congress 4 July 1864. The original two-year course was changed to four years in 1874 and continued in vogue till 1882, when on 5 August Congress amalgamated the cadet engineers and midshipmen and they are now known as naval cadets. The cadets then took the usual six years' course at the Academy and upon completion of the third year of the course were divided into an Engineer Division and a Line Division in proportion to the vacancies that have occurred in the several corps during the preceeding year. At the end of the six years' course appointments to fill vacancies in the line and in the Marine Corps were made from the Line Division, and to fill vacancies in the Engineer Corps from the Engineer Division. If, after making assignments as above, there should still be vacancies in one branch and surplus graduates in the other, the vacancies in the former were filled by assignment to it of surplus graduates from the latter. This arrangement was in vogue until the Line and Engineer Corps were amalgamated under the act of 3 March 1899, at which time the Engineer Corps ceased to be a separate organization, the older officers now being required to perform engineering duties only, whereas the younger officers must pass examinations in navigation, gunnery, seamanship, etc. A grade of warrant machinists to perform watch duties was also established because of the lack of commissioned officers for this work. See NAVAL ACADEMY, UNITED STATES; NAVY; NAVY OF THE UNITED STATES.

Engineering is, in its strict sense, the art of designing, constructing, or using engines, but the word is now applied in a more extended sense, not only to that art, but to that of executing such works as are the objects of civil and military architecture, in which engines or other mechanical appliances are extensively employed. Engineering is divided into many branches, the more important being civil, mechanical, electrical, mining, military, marine, and sanitary engineering.

Among the most notable of the engineering works belonging to very remote antiquity are the pyramids of Egypt. The rude stone monuments of the north, as at Stonehenge and Carnac, also testify to some engineering skill. The harbors and temples of ancient Greece are very memorable. The buildings of ancient Rome — its theatres, temples, baths, and aqueducts, its roads, bridges, and drainage-works, vie in extent and magnificence with the most celebrated works of modern times. From that period down to the commencement of the 18th century the most extensive works executed were the canals, embankments, and other hydraulic constructions used by the Dutch for the purposes of inland navigation, and to protect their low lands from the sea; the canals of North Italy; and the cathedrals and fortifications of mediæval Europe.

If the question were asked as to the characteristic feature of the modern applied science of engineering, the reply would undoubtedly be: "The wholesale manner in which work is carried on." It is not so very long ago that everything except the smallest articles and those required in great quantity were made singly, or at least in small lots; and even when standardizing and interchangeability were introduced these methods were by no means used in a way which showed a realization of their possibilities. The present tendency, on the contrary, is toward the elimination altogether of things which cannot be made wholesale; and methods which formerly applied to fire-arms, sewing-machines, typewriters, and the like are now in general use in the manufacture of steam-engines, machine tools, electrical machinery, and nearly all mechanical products.

This has been brought about by a combination of two processes: (1) the standardization of methods of manufacture; and (2) the discouragement of the demand for special articles. Formerly the customer told the manufacturer what was wanted, and the latter hastened to produce it. Or the plans and specifications for a certain structure were prepared by a consulting engineer, and all bidders were required to conform to these documents in the minutest details; no two such specifications being alike. At the present time the customer, knowing what he wishes to accomplish, seeks to do so as best he may by means of the standard articles in the market; or if it be a great engineering structure, the engineer specifies only the general requirements to be met, leaving each manufacturer to meet these with his own standardized product. The influence of these modifications in engineering practice extends to the manufacture and supply of materials.

The result of this concentration and standardization has been to reduce costs very materially and render possible undertakings which would otherwise be prohibitory in price. While to a certain extent it has obliterated individuality in design, it has also removed much useless repetition, and has prevented needless expense in the production of rival machines, differing but slightly in design, yet requiring duplications of drawings, patterns, and tools. There is little doubt that it is to this wholesale development of various departments of engineering work that the rapid extension of the share of the United States in the work of the world is largely due. See MECHANICS.

Engineering, Civil. In order to understand clearly what constitutes civil engineering it will be desirable to consider briefly the steps by which the different engineering professions have been developed and differentiated from one another. The profession of engineering is as old as the most elementary civilization. Up to about the middle of the 18th century there were but two recognized branches of the profession, the civil and the military. The former included all those branches not directly connected with military operations and the construction of fortifications. But the remarkable series of mechanical inventions which distinguished the last third of the 18th century — such as the spinning jenny by Hargreaves, the spinning frame by Arkwright, the mule by Crompton, the power loom by Cartwright, the steam engine by Watt, the puddling process by Cort, and others — followed in the first third of the century just ended by the development of the steam locomotive by Stephenson, the steamboat by Fulton, and by further great improvements in the manufacture of iron and steel, led at length to the differentiation of several branches from the parent stem of civil engineering. Up to that time civil engineering corresponded to what is now the general profession of engineering, and which has probably never been better defined than it was 75 years ago by Thomas Tredgold, as "the art of directing the great sources of power in nature for the use and convenience of man." The first branch to leave the parent stem was mechanical engineering, followed by metallurgical and mining engineering as the developments in the mining and reduction of metals progressed. Thus it stood till about the middle of the 19th century, since which time the tremendous advance in all branches of applied science has speedily differentiated engineers into the classes named, and into others. For instance, within the last quarter of a century the perfecting of the electric motor and the other great discoveries in electrical science have led to the development of electrical engineering as a distinct profession, the increasing importance of the application of chemistry in manufacturing has produced the chemical engineer, while the advances in sanitary science and the discoveries with reference to the nature, causes, and prevention of disease have resulted in the development of sanitary engineering as a branch quite extensive enough to constitute a profession by itself.

But nothwithstanding the divergence of all these branches, even what is left properly included under the title of civil engineering remains undoubtedly the widest in scope of all the engineering professions, and in practising it a man must become a specialist in some one branch. To enumerate its various fields, it comprises: (a) the construction of railroads, of roads, of street and interurban railways; (b) the improvement of rivers and harbors, the construction of canals, of lighthouses, and other works necessary for carrying on maritime trade and commerce; (c) structural engineering, or the construction of bridges, aqueducts, foundations, steel frames for buildings, etc.; (d) hydraulic engineering, including the development of water powers and the construction of dams and power plants up to the point at which the mechanical engineer is called upon to supply the motors; (e) surveying, which is necessary in the laying out of works of all kinds, but constitutes a branch by itself known as land surveying when applied to the object of measuring and subdividing land, and which is known as topographic surveying when the object is to represent upon a map the surface configuration of the land, and which, further, when extended to the survey of very large areas in which the curvature of the earth must be taken into account, leads to the intricate and interesting problems of geodesy, or the measurement of the earth, and touches upon the field of terrestrial physics; (f) it further includes a great variety of problems due to the congregating of persons in cities, such as works of water supply and sewerage, the drainage of lands and buildings, the disposal of wastes, and the construction and maintenance of city streets and pavements. This last group of problems (f), involving the preservation of the health of communities, is rapidly becoming, if it has not already become, the special field of the new profession of sanitary engineering.

The field of the civil engineer, it is evident, touches at many points the other engineering professions. In the construction and operation of steam railroads and electric railways his work comes in many ways into contact with that of the mechanical and that of the electrical engineer, and the same is true in the development of water powers, the construction of pumping stations, and other work of the hydraulic engineer; while in the problems involved in the construction of the foundations and steel frames for high buildings the civil engineer comes into intimate relations with the architect, with whom he must collaborate. The work of the sanitary engineer also comes in many ways into relation with economic, sociological, and legal problems of importance and difficulty.

We may next inquire as to the qualities which fit a man for success in this profession. In the first place, it is evident that the ideal civil engineer must be a scientific man and at the same time a business man. He must have a thorough knowledge of the laws of nature, the fundamental principles of mathematics and mechanics, and the materials of construction, for his work consists in applying those laws, principles, and materials so as to make them of use in the world's business. He must be essentially a man of action. The engineer takes the discoveries of the scientist in his laboratory or the book-worm in his study, and makes them available for the use and convenience of man. His dominant quality must be practical common sense, combined with habits of care and accuracy, and with the courage and training which will enable him to solve new problems and to meet emergencies with success. His mistakes may be very costly, and his opportunities for effecting economies by skilful design and construction very great.

It is often assumed that in order to be a successful engineer a man must be a fine mathematician. As a matter of fact, while the engineer should be thoroughly familiar with the fundamental principles of mathematics up to and including the calculus, he seldom uses any but the simplest applications. In geometry, and especially in trigonometry, he must be thoroughly at home. I should rather be inclined to say, however, after these explanations, that in order to be a good engineer a man must not be what would usually be called a fine mathematician, or at least that he must in addition possess other mental qualifications which are of far greater consequence; for mathematics is in its essential conceptions and methods an abstract science, and the great mathematician is apt to lack the qualities of action, the quick decision, the accurate judgment, the ingenuity in meeting and overcoming obstacles and the natural grasp and insight leading him to see the physical possibilities of a situation which must distinguish the successful engineer. On the other hand, the engineer should have a liking for mathematics, and a quick and instinctive grasp of its principles and methods, together with the insight which will enable him to see how they are to be made of use, and to use them properly when the time comes.

The training of the engineer must be mainly a training in science, and such a training tends to develop the quality of honesty. The only aim of the true scientific investigator is to arrive at the truth concerning the phenomena he is studying. Such a training, if combined with business ability, makes the very best administrators, and whether for this reason or not, engineers are being more and more sought after to fill administrative positions, especially in connection with corporations in which engineering is concerned. On the other hand, the early practice and associations of the engineer are often of a character which fails to produce polished manners or a good address and appearance, the lack of which is sometimes a great handicap.

There have been, and are, two ways of preparing for the practice of this profession. The first is to begin by getting a thorough technical training, in a good engineering school, in the principles underlying the profession. The second is to begin as an apprentice or student in an engineer's office, gaining experience, and studying at the same time. At the present time it may be stated unhesitatingly that the only proper and safe way to become an engineer is to pursue the first method and secure a preparatory training in one of our engineering schools. In this way the student will learn many things that most men will never learn in practice; he will gain habits of study, breadth of view, and the adaptability which will enable him to meet new problems. Moreover, the young man who aims to become an engineer should secure a broad training, not devoted entirely to technical subjects, but covering also those subjects of a general nature which are necessary for every thoroughly educated man. The engineer of the past has too generally been considered a mere builder, and he has not as a rule been given the position to which his responsibilities and his achievements legitimately entitle him; but the engineer of the future should aim to take a position in society and business as a cultivated and highly trained man, on a level with men in any of the other professions.

The broad and thorough education advised can now be obtained at many schools in this country. Many educators would advise a young man to take first a college course, and to supplement it by a course in a professional school. Another plan, which has its advantages, is to lay out a course longer that the usual college course, in one institution, directed from the beginning toward the end in view, some general subjects and some professional subjects being studied in each year, with an increasing proportion of the latter toward the end of the course. The latter plan has the advantage that the student is working always toward a definite end, provided he is able to decide at the beginning what general line of work he desires to pursue. Some of the technical schools of the United States have provided courses of five years or more, in which the student may gain a technical training and a liberal training at the same time. If a young man is unable to decide upon a profession at the beginning of his course, whether he goes to college first or not, he should at least decide within broad limits, in order that he may arrange his studies so as to avoid unnecessary waste of time when he finds himself able to make a definite choice. It is not at present necessary to go abroad to obtain a technical training in civil engineering. Our American schools now offer better preparation for the practice of the profession in America than can be obtained elsewhere, being well equipped, and teaching American methods. Twenty years ago this could not be said, but at present our technical schools are as good as any in the world. Fortunately, also, many of them offer scholarships or other aids to needy but capable young men, so that the lack of money need not prevent a persevering man from gaining a technical education.

The opportunities presented to a young man graduating from one of our engineering schools will be many and varied. All professions are over-crowded in the sense that there are men in them who cannot find employment, and this is true in civil engineering. Yet there are few professions which offer so many opportunities to properly qualified men, so that, properly speaking, it is very far from over-crowded. The young civil engineer will, moreover, find open to him many purely business positions for which his training will have fitted him. The range of the engineering professions is continually widening, one direction in which they are rapidly extending being that of administration. Within the past 60 years nearly the entire railway system of this country has been built, most of our factories started, and our works of sewerage and water supply constructed. These works have required the services of most of our engineers, while the opportunities of profitable employment here have attracted many members of the profession from foreign shores.

The civil engineer of the past has been mainly a constructor; the civil engineer of the future will be more and more an administrator as well. And while the construction of railroads will not proceed as rapidly in the future as it has in the past, there are certain directions in which construction will proceed with great activity. For instance, although the great era of railroad construction may be said to be substantially ended, there is still much work to be done in building branch lines, in double tracking existing lines, in reducing grades and curves and making other local improvements, often on a large scale. Moreover, the construction of urban and interurban electric lines, for the attainment of rapid transit in cities, and the improvements in steam railroad terminals, is proceeding and will proceed, at a rapid rate, and will require the expenditure of many millions of dollars, while the rapid growth of urban population and the advances in sanitary science have recently given a great impetus to the construction of works for supplying pure water and for disposing of the sewage and other wastes without injury to the public health. Further, it is becoming recognized that the man with common sense and a good technical training, if he have also a talent for organization and executive ability, is the best type of man to direct the work of our great industrial corporations. Some of our large railroad corporations have within comparatively few years instituted the practice of choosing their higher officers from their engineering corps, instead of from other branches of the service. Not a few railroad presidents began their careers as civil engineers, and the number of such men will increase in the future.

The field of the civil engineer, therefore, and the same is true of other branches of the profession, is all the time widening, and widening largely at the top, where there is always room, as well as in the lower ranks. A young man should aim to begin his practical experience at the bottom of the ladder, in whatever line of work he may engage, learning thoroughly every detail of the business.

With respect to financial remuneration, the civil engineer stands at an advantage compared with members of some professions in the fact that his services are in demand at the outset, at a fair salary, while the young doctor or lawyer may not be able to meet his expenses for some years. The ultimate financial possibilities presented to the engineer may not be as great as in the professions referred to, but the rewards are still sufficient to tempt even the most ambitious men, while there are few impecunious engineers. The engineer will be appreciated more and more as time goes on. The profession is a growing one, with great possibilities, and few careers offer greater inducements or a surer or truer success to the energetic and capable young man, for we live in a mechanical age, and the work of the man who can "direct the great sources of power in nature to the use and convenience of man" must continually increase in importance.

George F. Swain,
Massachusetts Institute of Technology.

Engineering Education. See Education, Engineering

Engineering, Electrical. See Electrical Engineering.

Engineering, Hydraulic. See Hydraulic Engineering.

Engineering, Marine, is partly military and partly civil, embracing naval architecture, building and operating of ships and naval accessories. In the military sense, it comprises the construction of war vessels and the construction and placing of torpedoes, submarine mines, etc. See Navy; Naval Construction; Submarine; etc.

Engineering, Mechanical, is that branch of the science and art of engineering which relates specially to machinery. It is closely allied to all other classes of engineering, inasmuch as there is hardly an occupation or industry in which machines of some sort are not directly or indirectly concerned, and it is often, for this reason, difficult to draw the line clearly between one class and the other. The civil engineer who plans and supervises the building of a railroad, calls to his aid the machinery used in excavating, blasting, building masonry, and numberless other mechanical processes required in the work, all of which are the result of mechanical engineering. Electrical engineering would accomplish comparatively little in the production of light and transmission of power were it not for the dynamo and other machinery on which dependence is placed for the manufacture and use of electric current. Mining engineering would be of little use in devising means for extracting the coal and mineral treasures buried in the earth if suitable machinery planned by mechanical engineers could not be employed to assist the labor of men. In marine engineering it is the mechanical engineer who designs the steam plant which produces the motive power for the propulsion of the steamship, and without his assistance there would be no such a thing as a steamship. In dealing with problems relating to waterworks, the hydraulic engineer would be powerless if he could not make use of the pumps and hydraulic machinery which the mechanical engineer has devised. In every kind of industry where power is required, whether it be connected with engineering, architecture, chemistry, agriculture, or any other subject, the mechanical operations involved are based on the continuous operation of the machine constituting the motive power, whether it be a steam engine or water wheel or other motor, and these are the products of mechanical engineering. When we come to fully analyze the subject, therefore, it appears that mechanical engineering so far underlies engineering of every class, and all kinds of industrial operations, that it can almost be said to sustain the whole fabric of modern civilization.

Mechanical engineering, in its strictest sense, relates simply to the design of machines. In its broad sense it covers not only their design but all matters relating to their proper construction and operation. In its common application it has for its scope both the design and construction of machines required for performing certain desired operations, and in addition the design and operation of the complete industrial plant, of which the individual machines form a part, and the construction of the plant in such a manner as to secure a successfully working whole for whatever purposes the plant is built. A large part of the mechanical engineering required at the present day consists in the assembling of machinery to produce certain desired ends, rather than in the design of the machinery itself. In many cases, the machinery has already been designed and constructed by engineers of the past and the perfected machines can be had by purchase in the market. This class of mechanical engineering covers a wide field. Perhaps its scope in this field can best be shown by referring in some detail to a familiar example. Take the case of the engineering required in a large modern hotel. The mechanical plant of such an establishment embraces a great variety of machinery, among the most important of which are the machines and appliances required for power, heating, ventilation, lighting, elevator service, distribution of hot and cold water, fire protection, refrigeration, ice-making, laundry work, and cooking. The work of the engineer, although confined mainly to the mechanical plant, must, at the very outset, be directed to the building itself. The building, no doubt, accords with the modern ideas of construction which call for a framework made of iron, in the design and construction of which the architect must have the assistance of the mechanical engineer. Not only this, but there must be, at the outset, a careful consideration of the required location of the various mechanical appliances, so that in working out the details of design relating to the building the architect may provide the necessary amount of room. He must leave a place for the boilers, engines, dynamos, pumps, etc., which make up the steam plant, and room also for the storage of coal. Provision must be made for the reception of flues, ducts, pipes, and wiring, which pass up through the building and which are distributed here and there to the different rooms. The character of the structures which may be needed for supporting the machinery, and the location of such structures, must also be planned at the outset so that the building may be prepared for them before it is too late. In the design of the mechanical apparatus, one of the first questions for the engineer to consider is the size and character of the steam plant. In dealing with this matter, he ascertains all the uses to which steam is applied, embracing the generation of power, the pumping of water, the supply of steam for all kinds of heating and cooking, and that required for ventilation. With the data thus obtained he determines the total amount of steam required for all purposes, and then calculates the boiler capacity needed to furnish the steam. For the next step, he decides upon the type of boiler best suited for the purpose, whether fire-tube or water-tube, horizontal or vertical, or whether internally or externally fired, and fixes upon the number and size of the units as well as their location. He then makes a plan showing the location of the boilers in the building; the style of the brick setting, if externally fired; the arrangement and location of the smoke flues, and of the stack or chimney to which they connect. Having done this and settled all matters relating to the accessories which form a part of the boiler plant, he takes up, in due course of time, the remaining portion of the work relating to the boiler plant, which may be described at this point because it is representative of much of the work which requires to be done in relation to the other departments of the plant. He draws up specifications describing in full detail the character of the boiler plant desired and what is expected of it as regards capacity and economy. These specifications are submitted to boiler manufacturers who are asked to furnish proposals for the construction of the plant in the manner described. When the proposals of the different bidders have all been received, the engineer examines them, and after consulting with the owner of the property, selects one of the parties with whom to contract for doing the work. Next follows the inspection of the boilers in process of construction in the shop and erection in the building, the object in view being to determine if all the terms of the specifications are complied with. Finally, when the plant is completed and the contractor sets it to work, the engineer submits it to whatever tests may be required, and thereby determines whether the guarantees which have been made regarding the capacity and economy are fulfilled, and whether the plant performs its work with that degree of success and satisfaction that is called for by the specifications. Referring now to the construction of the remaining departments of the mechanical plant, the next thing considered is the motive power. The greater part of the power in such a plant is likely to be transmitted by electricity, and consequently, the motive power is that required for generating electricity. (See ENGINEERING, ELECTRICAL.) After deciding on the number, size, and type of the engines and generators, he must then locate them, and make a plan showing their respective locations with reference to the boiler plant and other parts of the building. At the same time, there must be laid out on the plan a system of steam-piping connecting the boiler to the engines, and this must be arranged with a view to supplying steam to all other points of use, including the heating of the building. Next in order, the pumping machinery requires attention. This embraces the boiler feed pump, the various pumps used for the different classes of hotel work, the elevator pump, if the hydraulic system is employed, and the fire pump. The engineer must determine the proper size of each one according to the amount of water to be pumped, and he must select the type of pump, fix its location, show it on the plan, and extend the system of steam-piping to furnish each with the proper supply. He must also plan the exhaust piping required for each engine and pump, the necessary vent pipe for carrying the waste steam to the atmosphere, and, if exhaust steam is used for heating, the required connection of the exhaust pipe to the main supply of the building. There must be a heater provided in the exhaust pipe system for heating the feed water before it is pumped to the boilers, and another heater for the supply of hot water to the building, and both of these, in their selection, location, and connection, require the careful attention of the engineer. They must be properly laid out and shown on the plan. A complete system of water piping is required, connecting boilers, pumps, hydrants, and elevators, to say nothing of the hot and cold water supply pipes which extend to the various rooms of the hotel, and the location of these must likewise be shown by means of a suitable plan. Not the least important part of the mechanical engineering for the building is the design and construction of the heating and ventilating apparatus. Calculations of the amount of heat and radiating surface needed, the quantity of air required to be changed in a given time, and the sizes of the mains and returns, are involved in this work. Here, also, the kind of the system to be employed, the location and type of the heating and ventilating apparatus, including all the necessary details, are questions which the engineer must consider and decide, and the results must be indicated by proper plans. These various parts of the work are made the subject of detailed specifications, in the manner already referred to, and, likewise, proposals for the installation of the work are obtained, contracts awarded, inspection carried on during construction, and the work tested for acceptance when it is completed, all of which is done under the jurisdiction of the mechanical engineer. In much the same manner, the selection, location, construction, and installation of the remaining parts of the mechanical plant, embracing elevator machinery, laundry machinery, refrigerating machinery, ice-making machines, and the many other appliances concerned in the work of the hotel, are carried out under his supervision.

The same class of mechanical engineering as that referred to in the above example is that involved in the design and construction of industrial plants of various kinds, such as cotton- and woolen-mills, bleacheries, paper-mills, rubber-mills, machinery and other manufactories, this branch of the profession being commonly known as mill engineering. In all of these cases, the elementary parts consist of the power plant, which is sometimes operated by steam, sometimes by water, and often by both, the machines in the mill or manufactory, and the pulleys, shafting, and belting required to transmit the power from the one to the other. The work of the mechanical engineer in these plants consists in properly assembling the various machines so as to perform their functions, the selection of an appropriate power plant, and the proper design and arrangement of the transmitting apparatus required for operating them.

The work of the mechanical engineer is of paramount importance in the construction of steamships. Not only does the design of the boilers and engines on which the whole operation of the ship depends originate with him, but he is also concerned in the design, location, and connection of the multitude of auxiliary steam appliances which abound throughout the vessel and which contribute so much to the comfort of the passengers. The modern steamship is required to contain all the appointments of a first-class hotel. The services of a mechanical engineer are many times more needed in its design and construction than in that of a hotel, for the reason of the contracted space in which the machinery is necessarily enclosed.

One of the most important industries in which the mechanical engineer is a leading figure is that of the steel-rail-mill. Here the plant, which is distributed over many acres of land, embraces immense blast furnaces where the pig iron is made, elevators by which the raw material is lifted to the top of the furnaces, blowing engines which produce the air-blast required at the base of the furnace, converters in which the iron is changed to steel, hydraulic lifts by which the converters are manipulated and the steel blooms moved to cars, trains of rolls with their powerful direct-connected driving engines where the rails are rolled from the masses of white-hot metal, together with their re-heating furnaces, and, in addition to all these, the extensive boiler plants, and the system of piping and other apparatus required for conveying and supplying the boilers with waste furnace gases, on which they largely depend for fuel. The mechanical engineer who lays out and assembles the parts of which such a plant is composed has a task the magnitude of which is commensurate only with the importance of the interests involved.

Since mechanical engineering includes in its scope not only the proper design and construction of machinery but also its satisfactory performance, one branch of the profession relates to the determination, by means of suitable tests, whether the desired performance has been realized. This has especially to do with boilers, engines, and apparatus using steam, which the engineer requires to be installed under specific guarantees of performance. The performance of boilers in the matter of economy is specified in terms of a certain number of pounds of water evaporated per pound of coal, and, in that of capacity, in terms of the number of horse-power developed, while that of the engine is specified as the number of pounds of feed water or dry steam consumed per indicated horse-power per hour. The performance tests require the determination of the quantities stipulated, by actual measurement of the coal, water, and power consumed under working conditions. Another branch of mechanical engineering, in a similar line, relates to the testing of materials used in construction, the object being to determine whether they have the requisite strength and physical characteristics. A sample or specimen of the material is placed in a testing machine and submitted to an actual breaking force and the amount of strain ascertained by measurement.

Having now given some explanation regarding the character of the profession of mechanical engineering, the question naturally arises as to the qualifications needed to make a success of such a profession. It hardly needs to be said of this profession more than of another that the one who adopts it should do so not merely as a means of livelihood, but because his tastes lie in the direction of mechanical pursuits, if, indeed, he does not love the profession for its own sake. No one should enter the profession who is not fond of machinery, who is not a "born mechanic" as the saying is, or who is not deeply interested, to say the least, in every kind of machine. But apart from natural inclinations, there are qualifications that especially fit one for the work of a mechanical engineer. He should have a technical education so as to be thoroughly grounded in the principles of mechanics. He should not only understand these principles but he should know them by heart. He may or he may not remember the formula derived from the principle, but the principle itself should ever be at his finger's end. He should be familiar with mathematics, geometry, and trigonometry. He should know the strength of materials and be able to calculate the strains occurring in structures and in machines, both at rest and in motion, so that he may design them with the proper amount of strength, or, if already designed, that he may be able to prove that they are of sufficient strength for any purpose he may desire to use them. He should know their behavior under varying conditions, and should be able to detect their points of weakness and know the best methods of strengthening them when they fail. He should be a draughtsman and, what is the draughtsman's next neighbor, an inventor. He should know the processes involved in the work of the patternmaker, founder, blacksmith, and machinist. He should know how to erect machinery, and how to operate it after erection. He should know the practices of the trade, and he should know the various articles concerned in mechanical operations which can be bought in the market, and, in a general way, their cost. He should be familiar with the different kinds of engines and boilers, pumps, water wheels, etc., in the market, and their relative advantages. Not the least in importance should he be grounded in the principles of steam engineering and the laws which pertain to the generation and use of steam, not only for the operation of engines of various kinds, but for the various kinds of steam heating. He should be familiar with the steam engine indicator and be able to test a boiler or engine for capacity and economy. He should be well versed in hydraulic, pneumatic, and electrical machinery. He should know about the construction and operation of the various machines of the plant he has assembled, so as to be able to judge of the correctness of their design and construction, and whether they perform their functions in a proper manner, and according to the specified requirements. He should be able to prepare detailed specifications of the work he plans, and he should possess sufficient literary ability to draw up a suitable report upon any question that may arise regarding the work he is called upon to perform, and pass judgment upon the comparative merits of different makes of machines required for a given purpose or of the different modes of carrying on given processes. In a word, the mechanical engineer must be skilled by observation, by study, and by experience in the science and art of the profession from beginning to end.

One of the leading problems confronting the mechanical engineer, whatever the special line in which he is engaged, is the reduction in the cost of production, and, what is allied to it, the attainment of the maximum result from machinery with the least expenditure of money, time, and labor. As machines and processes are in a continual state of improvement, and almost all lines of business are in a continual state of growth, it does not require many years to elapse after a piece of engineering work has been completed before it must be remodeled or enlarged to meet the demands of the times. This problem of reducing the cost of production is, therefore, one which is continually before him. In the design of an individual machine, the highest aim is to reduce the number of parts and quantity of material used to the smallest amount consistent with proper operation, and to run it at the highest speed which can be safely and successfully maintained. In arranging a plant for carrying on some industrial process, the aim must be to employ machinery wherever it is possible to save the labor of men, and assemble the machines so that the least number of hands and the least expense is required to change the raw material into the finished product. Following in the same direction is the aim to save all unnecessary waste of fuel or energy required in operating the machinery, whatever the class of work and in whatever department of the work such waste may occur.

There are many notable problems of a more specific nature than the one just named which absorb the attention of mechanical engineers and await their solution. One of these is the reduction in cost of steam power. Owing to the great amount of heat which passes to waste through the escaping of exhaust steam to the atmosphere or to the condenser, amounting in the most economical engines to no less than three fourths of that required in the original generation of the steam, there is a wide field for improvement in steam engine economy. Efforts are being made to reduce this waste by employing a part of the heat thus lost for evaporating some other liquid having a sufficiently low temperature of evaporation, and using the vapor thus formed to generate power in an auxiliary cylinder, thereby adding to the total power developed by the engine, and reducing in a corresponding degree the cost of the power per horse-power. Another problem of the same kind is the substitution of some other motive power for the steam plant with the object of reducing its cost. Gas, oil, and other forms of internal combustion engines are being widely developed for this purpose. In the conversion of coal into gas by the employment of a gas producer, and the subsequent use of the gas in the cylinder for developing power, the cost has already been reduced below that of steam power, and even better results may be expected.

The development of the steam turbine and its substitution for reciprocating engines is one of the problems on which mechanical engineers are most diligently working. The advantages to be obtained from this form of engine are the reduced space, increased speed of revolution, and greater uniformity of rotation which the turbine principle secures. There is a special field for its use in the operation of electric generators and in the propulsion of steamships, in both of which there is promise of most efficient results. The belief prevails that in the proper application of the turbine engine to marine work will be found the solution of the problem of rapid transportation by water.

Another great problem of mechanical engineering which is of importance to all business interests, is that of rapid transportation by railroad. The excellent results that have already been accomplished in this direction on short lines of suburban travel are due to the application of electricity, and the wide introduction of the electric railroad makes this a familiar subject to everyone. On steam railroads the efforts for increasing speed on long lines of travel do not lie in the direction of any radical departure from existing practices, but rather in the perfection of details whereby locomotives of greater power and cars of better construction are employed, the road-bed improved, and all the various details of railroad travel arranged so as to secure the most expeditious handling of trains. How best to provide a marked increase of speed on railroads, whether by the application of electricity, or by some new and untried method, is one of the problems still unsolved.

The great problem of aërial navigation is one which naturally lies in the domain of mechanical engineering. Although much has been done experimentally in this field, and there are instances of air-ships being constructed and successfully propelled for short distances at low speed, the practical solution of the problem has thus far baffled all efforts. One of the most encouraging experiments has been made by using a suitably shaped balloon and employing a gasoline engine connected to screw propellers for motive power; the engine being of high power in proportion to its weight, and the steering being effected by a rudder. Experiments have also been conducted with aëroplanes, in the hope of obtaining through these devices the necessary supporting power for the weight to be carried, and thereby dispensing with the use of balloons. With the same end in view, the motion of the wings of large birds has been studied for the purpose of determining the natural laws which govern aërial travel, and, if possible, copying them. In neither of these lines has much success been attained.

There are other great problems of mechanical engineering, yet unsolved, which relate to the production of power by the employment of the forces of nature not heretofore utilized. One of these has for its object the utilization of the sun's heat. It has been worked out in a small way in California. A concave mirror having 1,000 square feet of surface has been employed for converging the rays of the sun upon a steam boiler which lies at its focus, and suitable mechanism is arranged for keeping the mirror always turned in the proper direction toward the sun. It is said that in full sunshine this apparatus has developed 10 horse-power. Wind power is widely and successfully employed on a small scale, but there remains the problem of overcoming its variable nature by providing means for storing it, and of applying the power thus obtained without limitations. The development of tidal power, like that of wind power, is largely a problem of the storage of energy, and no success in this field has been realized.

What the future offers to a young man choosing the profession of mechanical engineering depends very much upon the ability of the man himself. The broad scope of the profession, already referred to, furnishes ample indication that there is a wide field of work for him. That there are positions awaiting the young engineer may be seen by examining the catalogues of prominent technical colleges, which record the names of graduates and their occupations. Referring to one of these catalogues, and taking as a sample the last graduating class given, that for the year 1902, there are recorded a total of 44 mechanical engineers. Of this number only 3 are put down without employment, and 1 of the 3 is in reality employed, being a graduate student. Of the 41 holding positions, 18 are engaged in various engineering occupations connected with the manufacture of machinery, 3 are employed in textile mills, 8 are engaged in steel works, 3 are connected with railroads, and the remaining 9 are variously occupied in engineering pursuits. If the young engineer becomes connected with an industrial business of sufficient size and importance to warrant the steady employment of a mechanical engineer, and he shows the necessary ability, the prospect is that he will in time push forward to a position of responsibility which will command a good salary and satisfy any ordinary ambition. If his desire is to establish an engineering business of his own, he can make the emoluments greater than in a salaried position, provided he is able to secure the necessary clientage, and conduct such a business to advantage. If this is his choice, the most promising course for him to pursue is to first enter the office of a successful engineer, and spend a few years in learning the business. Then, if he has the acquaintance and aptitude necessary for attracting business for himself, he can set up his own establishment, and by careful attention to the execution of his work strive for the success he seeks. In mechanical engineering, as in other professions, large emoluments await the men who rise to the top, for these are the engineers who are called upon by individuals and corporations for consultation.

The profession of mechanical engineering offers as many attractions to those entering it as any other profession, for in this, as in others, there is always room for those who excel, and no professional man meets with success unless his work commands it.

George H. Barrus,
Expert and Consulting Steam Engineer, Boston.

Engineering, Military. The duties of the military engineer consist in the construction of fortifications, including the trenches and batteries required in besieging places; also of barracks, magazines, of roads and bridges to facilitate the passage of an army. He should have a practical and theoretical knowledge of gunnery. In this country he is often called upon to undertake works which more properly belong to the business of a civil engineer, such as the survey of the country, the inspection of public works, in fact, all the duties of a government engineer. See Gunnery; Ordnance; War; etc.

Engineering, Mining. See Mining Engineering.

Engineering, Sanitary. See Sanitary Engineering.

Engineering Education. Interesting statistics have been prepared showing the work of students in technical schools in the United States, as compared with the work of students in other countries. The following comparative table gives the percentage number of hours' instruction at Massachusetts Institute of Technology, Cornell, the Berlin Technical High School and the Zürich Polytechnicum that are devoted to each group of studies:

Study	M. I. T.	Cornell	Berlin	Zürich
Mathematics	8	5	14.5	19.2
Physics	5	8	6.8	6.0
Chemistry	7	7	1.7	3.0
Applied mechanics	7	10	22.5	19.5
Mechanism	4	......	8.0	......
Steam Engine; Thermo-dynamics	6	6	4.1	8.0
Mechanical, etc., Drawing	26	20	31.0	39.3
Electrical Engineering	2	2	3.4	5.0
Commercial subjects	2	......	8.0	......
Workshop practice	14	30	......	......
French	6	......	......	......
German	3	3	......	......
English	5	......	......	......
Engineering Laboratory	5	9	?	?
	100	100	100	100
Approximate hours	3000	3000	4000	4000
Course in years	4	4	3	3

Marked differences in theories of training is evidenced in these curricula. The American courses are more practical in character and require more laboratory training than is even recommended in the German plan, and they devote a large proportion of the time to teaching skill in handicraft. They give much less time to mathematics, and perhaps there may be a loss of power in mature life on this account, though it is certain that immediate and practical ends are gained by the American programme. See EDUCATION, ENGINEERING.

Engineering Instruments are principally the rod, compass, level and transit. See INSTRUMENTS, ENGINEERING; SURVEYING.

Engineering Schools. The education and training of the engineer in modern times have called for the establishment of technical schools and courses in engineering in the large colleges and universities. These schools provide the student with the theories of mathematics, mechanics, and engineering, and by means of extensive laboratory and outside work provide him with practice in the design, construction, and use of modern engineering appliances. Among the most noted technical schools are the University of Glasgow; Ecole Polytechnique, in Paris; Stevens Institute of Technology, in Hoboken, N. J.; the Massachusetts Institute of Technology, in Boston; and Cornell and Columbia universities. See EDUCATION, SCIENTIFIC AND TECHNICAL.

Engineering and Structural Terms. The following list includes some of the principal terms applied to designate the various mechanical units employed in engineering and structural operation. See also ENGINE; LOCOMOTIVE, DESIGN AND CONSTRUCTION OF THE MODERN; and WORKSHOP TERMS.

ABUTMENTS.— In structural work — the surfaces which support arches, beams, and bridges, and sustain the reactions due to the application of the load. In machinery — any relatively immovable part or surface designed to resist pressure, or to resist reaction. In carpentry — a joint of two pieces, the fibres of one being at right angles with those of the other.

ACTION.— The manner in which a machine or engine works. In mechanics it is axiomatic, that action and reaction are equal and opposite.

ACTUAL OR AVAILABLE HORSE-POWER — A.H.P.— See BRAKE HORSE-POWER.

ANNULAR.— Ring-shaped — as the annular seating or circular seating on which a pump valve rests; or the cylinder and piston of an annular engine.

APEX.— The point or summit of a cone, pyramid, or any triangular-shaped structure or figure. In engineering — the points of the triangles in truss girders, or those portions of the braces which intersect the flanges at the top and bottom.

AXIS.— The line which passes through the centre of a body. The axis of a cylinder, or of a sphere, is the right line which passes through the centres of all the corresponding parallel sections thereof. The axis of an ellipse, a parabola, or a hyperbola is the right line which divides the curves symmetrically. The "axis of symmetry" is an imaginary central line around which a symmetrical body is developed, and which passes through the centre of gravity of the body. The "neutral axis" of a beam is a longitudinal central line along which a beam is neither in tension nor compression. In a beam of uniform section it corresponds with the central line of the cross-section. In beams of varying section it corresponds to the mean of the bending sections.

BALANCE.— The equilibrium or equality of the moments, or the equality of the sum of the forces which tend to move or turn a body in one direction, to the sum of the forces which tend to move or turn it in the opposite direction.

BELT OR BELTING.—A band or strap of leather, india-rubber, or cotton, employed to transmit power over smooth pulleys. Belts act by friction only, and are extensively employed where an exact velocity ratio is not essential, and where the distance between the shafts prevents the employment of a positive means of transmission. The transmitting capacity of a belt depends upon its pull, or upon the lineal velocity at which it travels. The amount of pull depends upon the strength of the belt and the friction on the pulleys. The lineal velocity depends upon the diameter of the pulleys and upon the speed of revolution. Belts are also extensively used as conveyors of material such as coal, ores, grain, and finished products, in mining, milling, and manufacturing plants. They are made in a great variety of sizes both for power transmission and conveying purposes and range from 5 to 60 inches in width, and from 5 to 300 feet in length.

BELT TENSION.— The ultimate strength of belts ranges from 2,000 to 5,000 pounds per square inch, but these values are greatly reduced at the joints. At the laced joints, it ranges from 1,000 to 1,500 pounds, and at the riveted joints, from 1,500 to 2,500 pounds per square inch. The working tension usually maintained ranges from 30 to 60 pounds per inch of width.

BENDING MOMENT.— The sum of the external forces which act upon each side of a given section of a beam bending under a load. It is equal to the "moment of resistance" of that section, or the sum of the internal forces or stresses set up therein by the bending action.

BLOCKING OR BLOCKING-UP.— The elevating and supporting of large pieces of machinery, or entire structures, by means of cranes, jacks, and blocking or short lengths of timber and planks, during erecting and constructing operations. It is also applied to the elevation given to the outer rail of the curve of a railway track, for the purpose of counteracting the effect of the centrifugal force developed by a rapidly moving train.

BOLT.—A metal device employed by engineers for fastening purposes. Bolts are usually made of wrought-iron or of mild steel. In the ordinary forms, the head is forged with the shank, and the opposite end or tail is threaded to receive the screw nut by which it is secured. The heads and nuts are made either rectangular or hexagonal, and the shoulder or neck under the head is often made rectangular so as to fit into a square hole and thus prevent the bolt from turning around on its axis. For general purposes, the dimensions of bolts conform to certain standards. The United States standard is conformed to in America, and the Whitworth standard, in Great Britain and other European countries.

BRAKE HORSE-POWER — B.H.P.— The amount of power delivered by an engine at the driving pulley or power shaft, and actually available for doing work. The power developed by an engine is measured at two points — at the cylinder, as indicated horse-power, and at the driving pulley. Between the cylinder and the pulley a certain amount of power is lost in the friction developed in the running of the engine itself, so that the actual horse-power available for work is the indicated horse-power minus the horse-power lost in friction. It is sometimes expressed — D.H.P., delivered horse-power.

BRITISH THERMAL UNIT — B.T.U.— The amount of heat required to raise the temperature of water one degree Fahrenheit, at or about 39.1° Fahrenheit. Its mechanical equivalent as originally determined by Joule is 772 foot-pounds, but later determinations indicate that it is nearer 778 foot-pounds. To convert values of energy expressed in foot-pounds to their equivalents in British Thermal Units, divide the values by 778.

CAMBER.— The amount of upward curvature given to an arched bar or structure in order to compensate for the downward curvature resulting from the application of the load. In machinery, it is specifically applied to the arching of springs like those of locomotives. In structural work, it is applied to the arching of bridge trusses like the stiffening trusses of suspension bridges.

CANTILEVER.— A beam fixed at one end and loaded at the other, or loaded uniformly. In ordinary structural work it is represented by the brackets employed for supporting balconies or other overhanging platforms like the sidewalks placed on the outside the trusses of a bridge.

CENTRE.— The fixed point about which the radius of a circle or of a circular arc moves. It is extensively applied as a specializing prefix to other terms, as "centre gauge," "centre line," etc. The "centre of compression" is the line in which the resultant of the compressive forces in the lower part of a beam is located. The "centre of gravity" is the point in a body about which the body will remain balanced when placed in any position. The "centre of gyration" is the point in which the momentum of a revolving body is concentrated. The "centre of moments" is the point about which the forces applied to a rigid body act. The "centre of oscillation" is the point in the axis of a vibrating body, such as a pendulum, in which if all the matter of the body were concentrated, the body would vibrate in the same time. The centre of gravity and the centre of oscillation lie in the same axis, but the latter is located farther from the point of suspension. The "centre of percussion" is the point in a revolving body at which if the body struck an immovable obstacle, would result in the destruction of all of its motion. The "centre of tension" is the line where the resultant of the tensile forces in the upper part of a beam is located.

CIRCULAR INCH.— The area of a circle one inch in diameter, as distinguished from a square inch. The number of circular inches in a given diameter is obtained by squaring the diameter.

COEFFICIENTS.— Numerical values deduced from data obtained by experiments and used as constant multipliers in engineering calculations. They have been determined for friction, elasticity, tension, rupture, resistance, the flow of water, etc. For example — the amount of force or weight that will elongate an elastic bar of any material and of uniform section to twice its original length is designated as the "coefficient of elasticity" of that material. Also termed "modulus," as the "modulus of elasticity," the "modulus of resistance," etc.

COHESIVE STRENGTH.— The resistance of a material to rupture under tension. The same as "tensile strength," and equivalent to "tenacity."

COLUMN.—A beam set on end and receiving pressure vertically or in the direction of its longitudinal axis. The latter condition, however, varies with the length of the column. When the length is 25 to 30 times greater than the diameter, it is a "long column," and yields under pressure by bending only, in a manner similar to that of a beam supported at both ends. When the length is 3 to 5 times greater than the diameter, it is a "short column," and ruptures by crushing only. The resistance of a column to flexure is increased by flattening its ends, by extending the area of the ends, and by firmly fixing both ends.

COMPOUND MACHINES.— Those which are designed and adapted for performing several different kinds of work, either simultaneously, or at different periods of time.

COMPLEMENT.—A term employed in angular measurement. The complement of an angle is its difference from 90°.

COMPRESSION.—A term of various applications. A body is in compression when it is subjected to crushing forces which act in the direction of the axis which is continuous with the direction of pressure. The cushioning or resistance of the steam in the end of an engine cylinder to the return stroke of the piston. The pressure exerted on the explosive charge in the cylinder of a gas engine by the piston during its instroke previous to "ignition" of the charge.

CONCENTRATED LOAD.—A load localized or applied at a particular point upon a beam, girder, or structure. A concentrated load will produce twice as much stress as a distributed load.

CONSTANT.—A number deduced from data obtained by actual tests made upon the strength of a particular material, and used in calculations relative to the strength of structures built of that material. For example — having ascertained by actual experiment the weight required to rupture a steel bar measuring 3 x 2 x 1 inches, that weight can be used to estimate the stresses in structures made of the same material but differing in length, breadth, and depth.

COUNTRY CUT.— Timber or lumber which has been sawn into planks and boards in the district where the trees were felled.

COUPLE.— Two equal and opposite forces acting upon a body, which is, therefore, in a state of equilibrium.

CREEPING.— The slight loss of speed due to the slipping of the rope in the case of drums driven by rope gearing, and by the elasticity of the belts in the case of power transmitting belting. In either case the amount is very small per revolution, or for short intervals of time.

DANGEROUS SECTION.— The section of a bar at which the bending moment is greatest.

DATUM OR DATUM LINE.—Any base line from which measurements are made, or dimensions taken, either in actual work, or in graphical calculations.

DEALS.— Sawn timber which usually measures not less than 3 x 9 inches and not more than 3 x 12 inches in cross-section.

DIFFERENTIAL MOTION.— The motion resulting from the combination of the different motions of two parts of a mechanical device. It affords mechanical gain. For example — in the combination of the wheel and axle commonly called the "Chinese Windlass," two axles of unequal diameters rotate together so that the rope which passes through the movable pulley which supports the weight is wound up on the larger axle and unwound on the smaller axle. The upward movement of the weight is consequently very slow, but the mechanical gain is very great. In the case of the "differential screw," two screws of unequal pitch are cut on the same spindle. When the spindle is turned, a nut on one of the screws is moved by an amount equal to the difference in the pitches. A "differential strain" is one that is due to a variable load.

DOUBLE GEAR.— Gearing in which two wheels and two pinions are used. The arrangement affords mechanical gain. The principle is extensively employed in connection with the gear of lifting cranes, drilling machines, lathes, etc.

DRIVEN.—As applied to gearing, it refers to the wheel or wheels actuated by the "driver" or wheel attached to the driving shaft. To calculate the mechanical efficiency of a train of gearing, multiply the radii of all the drivers together, and likewise the radii of all the driven, and divide the latter by the former.

DUTY.— The performance or amount of work done by an engine as determined upon the basis of coal consumption, and stated in foot-pounds. The duty of a steam engine is the number of pounds raised to the height of one foot by the burning of a bushel of coal. In the case of pumping engines, the duty was formerly expressed in millions of pounds of water lifted to the height of one foot by the burning of 100 pounds of coal; but, as the quality of coal varies greatly, the basis now employed is the work done by 1,000 pounds of dry steam, or by 1,000,000 British Thermal Units.

EFFICIENCY.— The efficiency of a machine or of a structure, or any portion thereof, is the ratio of its strength, power, or capacity, to that of some predetermined, understood, or fixed standard of reference. For example — the efficiency of a riveted joint in plate work is its percentage strength calculated relatively to that of the solid plate. The efficiency of a machine is the ratio of its actual value to its theoretical value, or the difference between the amount of work expended on the machine and the amount given out by it or obtained from it.

ENCASTRE.— The immovable fixing of the ends of a cantilever, or the ends of other forms of beams or girders in a wall or support. Beams are much stronger when encastre than when simply supported.

FACTOR OF SAFETY.— When calculating the ultimate strength of a structure it is necessary to provide for contingencies arising from a lack of uniform quality in materials, inferiority of materials, wear and tear of parts, the unexpected application of loads, etc. This provision is made by the use of multipliers such as 4, 6, 8, and in some cases 10, which are applied to certain dimensions. For example — the application of a factor of safety of four will give a structure having four times the strength necessary to carry the load it will be ordinarily required to sustain.

GRAPHIC STATICS.— The graphical methods employed for ascertaining the strains on structures, velocity ratios, etc., by means of lines drawn to an uniform scale and representing the direction and intensity of active forces.

HOLLOW STRUCTURES.— The frames, standards, and parts of large machines and structures, made hollow from motives of economy, or to reduce their weight while retaining their strength. They are represented by the various forms of box girders, base plates, columns, etc.

HORSE-POWER.— A term used for expressing the power developed by a mechanical motor or engine. It was originally selected by James Watt as a basis on which to sell his engines. One horse-power is a quantity of work equivalent to that which is expended in raising a weight of 33,000 pounds to the height of one foot in one minute, or a weight of 550 pounds to the height of one foot in one second. It is expressed in foot-pounds, and is designated as A.H.P.— Actual or Available Horse-Power, or B.H.P.— Brake Horse-Power; N.H.P.— Nominal Horse-Power, a comparatively obsolete term used by some manufacturers to designate the size of an engine; I.H.P.— Indicated Horse-Power, the foot-pounds of work done behind the piston; and F.H.P.— Friction Horse-Power, the number of foot-pounds of power lost by the friction of the engine.

Interchangeable.—Applied to the parts of machines and structures which are made similar and in large quantities, so that a part taken from one may be used in any other of the same size and type.

Mean Effective Pressure.— The power exerted by the expansive energy of a gas in driving the piston of an engine. Being variable for different positions of the piston, the value determined is the average of the pressures at the various positions. It is usually determined by the use of an indicator or pressure gauge diagram.

Thermal Efficiency.— The ratio of the heat converted by an engine into mechanical energy, and the heat absorbed by it from the source of supply. It is limited by the range of temperature through which the working substance within the cylinder acts, and must be always a quantity less than unity.

Traction of Tractive Power.— The pulling power afforded by the frictional adhesion of wheels.

Ultimate Strength.— The strength of a material equivalent to the load which produces actual fracture. The ultimate strength as determined by actual test is usually employed in engineering calculations in preference to the elastic strength, as it affords data of a more definite character.

Units.— Mechanical units are of two classes — those derived from the relations of things having their basis in natural law, and those consisting of conventional standards adopted for convenience in calculations. For example — the Joule, the unit of heat, is based upon a natural and interchangeable fact, while the horse-power is simply a conventional standard accepted by engineers by mutual consent and use.

Velocity Ratio.— The proportional velocity of bodies which are mutually connected, such as levers, gear-wheels, etc.

William Morey, Jr., C. E.,
Consulting Civil and Mechanical Engineer, New York.

Engineers, Corps of, a branch of the military service of the United States, organized in 1802, as "The Corps of Engineers of the United States Army." There are similar organizations in all European countries. See Army; Army of the United States.

Engis, ŏn-zhē, Belgium, an archæological station on the Meuse, southwest of Liége, where a human skull was found imbedded in breccia, with remains of the rhinoceros and reindeer. There has been much discussion among archæologists as to the age of the skull, but it is most commonly referred to the Quaternary Period.

England, including **Wales,** the southern and larger portion of the island of Great Britain, is situated between lat. 50° and 55° 46′ N. and lon. 1° 46′ E. and 5° 42′ W. On the north it is bounded by Scotland; on all other sides it is washed by the sea; on the east by the North Sea or German Ocean; on the south by the English Channel; and on the west by St. George's Channel and the Irish Sea. Its figure is, roughly speaking, triangular, but with many windings and indentations, the coast-line measuring not less than 2,765 miles. The length of the country, measured on a meridian from Berwick nearly to St. Alban's Head, is 365 miles. Its breadth, measured on a parallel of latitude, attains its maximum between St. David's Head, in South Wales, and the Naze, in Essex, where it amounts to 280 miles.

Topography.— The chief indentations are: On the east, the Humber, the Wash, and the Thames estuary; on the west, the Solway Firth, Morecambe Bay, Cardigan Bay, and the Bristol Channel; those on the south are less prominent, though including some useful harbors. The greater part of the coast consists of cliffs, in some places clayey, in others rocky, and sometimes jutting out into bold, lofty, and precipitous headlands, as at Whitby and Flamborough Head on the east, Beachy Head, the Isle of Portland, the Lizard and Land's End on the south and southwest, St. David's Head and St. Bees Head on the west. The most extensive stretches of flat coast are on the east, in the county of Lincoln, and from the south part of Suffolk to the South Foreland in Kent, and in Sussex and Hants on the south coast. The chief islands are: Holy Island, the Farne Islands, Sheppy, and Thanet on the east coast; the Isle of Wight on the south; the Scilly Isles at the southwestern extremity; and Lundy Island, Anglesey, Holyhead, and Walney on the west.

The loftiest heights of England and Wales are situated at no great distance from its west shores, and consist of a succession of mountains and hills, stretching, with some interruptions, from north to south, and throwing out numerous branches on both sides, but particularly to the west, where all the culminating summits are found. The northern portion of this range has received the name of the Pennine Chain. It is properly a continuation of the Cheviot Hills, and, commencing at the Scottish border, proceeds south for about 270 miles, till, in the counties of Derby and Stafford, it assumes the form of an elevated moorland plateau. In Derbyshire The Peak rises to the height of 2,080 feet. By far the most important of its offsets are those of the west, more especially if we include in them the lofty mountain masses in northwestern England sometimes classed separately as the Cumbrian range. Amid these mountains lie the celebrated English lakes, of which the most important are Windermere, Derwent Water, Coniston Lake, and Ullswater. Here also is the highest summit of northern England, Sca Fell (3,210 feet). The Pennine Chain, with its appended Cumbrian range is succeeded by one which surpasses both these in loftiness and extent, but has its great nucleus much farther to the west, where it covers the greater part of Wales, deriving from this its name, the Cambrian range. Its principal ridge stretches through Carnarvonshire from north and west, with Snowdon (3,571 feet) as the culminating point of south Great Britain; across the Bristol Channel from Wales is the Devonian range. It may be considered as commencing in the Mendip Hills of Somerset, and then pursuing a southwest direction through that county and the counties of Devon and Cornwall to the Land's End, the wild and desolate tract of Dartmoor forming one of its most remarkable features (highest summit, Yes Tor, 2,050 feet). Other ranges are the Cotswold Hills, proceeding in a northeast direction from near the Mendip Hills; the Chiltern Hills taking a similar direction farther to the east and the North and South Downs running east, the latter reaching the southern coast near Beachy Head, the former reaching the southeast coast at Folkestone.

A large part of the surface of England consists of wide valleys and plains. Beginning in the north, the first valleys on the east side are those of the Coquet, Tyne, and Tees; on the west the beautiful valley of the Eden, which, at first hemmed in between the Cumbrian range and Pennine Chain, gradually widens out into a plain of about 470 square miles, with the town of Carlisle in its centre. The most important of the northern plains is the Vale of York, which has an area of nearly 1,000 square miles. On the west side of the island, in south Lancashire and Cheshire, is the fertile Cheshire plain. In Wales there are no extensive plains, the valleys generally having a narrow, rugged form favorable to romantic beauty, but not compatible with great fertility. Wales, however, by giving rise to the Severn, can justly claim part in the vale, or series of almost unrivaled vales, along which it pursues its romantic course through the counties of Montgomery, Salop, Worcester, and Gloucester. Southeast of the Cotswold Hills is Salisbury plain, a large elevated plateau, of an oval shape, with a thin, chalky soil only suitable for pasture. In the southwest the only vales deserving of notice are those of Taunton in Somerset and Exeter in Devon. A large portion of the southeast may be regarded as a continuous plain, consisting of the Wealds of Sussex, Surrey, and Kent, between the North and South Downs, and containing an area of about 1,000 square miles. The southeast angle of this district is occupied by the Romney marsh, an extensive level tract composed for the most part of a rich marine deposit. Extensive tracts of a similar nature are situated on the eastern coast in Yorkshire and Lincoln, where they are washed by the Humber; and in the counties which either border the Wash, or, like Northampton, Bedford, Huntingdon, and Cambridge, send their drainage into it by the Nen and the Ouse.

For the climate of England see GREAT BRITAIN, *Climate*.

Rivers.— England is well supplied with rivers, many of them of great importance to industry and commerce. Most of them carry their waters to the North Sea. If we consider the drainage as a whole, four principal river basins may be distinguished, those of the Thames, Wash, and Humber belonging to the German Ocean; and the Severn, belonging to the Atlantic. The basin of the Thames has its greatest length from east to west, 130 miles, and its average breadth about 50 miles, area 6,160 square miles. The river itself, which is the chief of English rivers, has a length of 215 miles. The basin of the Wash consists of the subordinate basins of the Great Ouse, Nen, Welland, and Witham, which all empty themselves into that estuary, and has an area computed at 5,850 square miles. The basin of the Severn consists of two distinct portions, that on the right bank, of an irregularly oval shape, and having for its principal tributaries the Teme and the Wye; and that on the left, of which the Upper Avon is the principal tributary stream. The area of the whole basin is 8,580 square miles. The next basin, that of the Humber, the largest of all, consists of the three basins of the Humber proper, the Ouse, and the Trent, and its area is 9,550 square miles, being about one sixth of the whole area of England and Wales. Other rivers unconnected with these systems are the Tyne, Wear, and Tees, in the northeast; the Eden, Ribble, Mersey, and Dee, in the northwest. The southern coast streams are very unimportant except for their estuaries. See THAMES.

Areas and Population.— The total area of England and Wales amounts to 58,323 square miles and the population (1901) aggregated 32,526,075, divided among administrative counties and county boroughs as follows:

ADMINISTRATIVE COUNTIES	Area in Sq. m.	Pop. 1901
Bedfordshire	473.3	171,700
Berkshire	713.3	180,366
Buckinghamshire	749.0	196,844
Cambridgeshire	492.5	120,634
Isle of Ely	371.9	64,494
Chester	1,009.2	601,070
Cornwall	1,356.6	322,960
Cumberland	1,520.4	266,924
Derbyshire	1,010.8	504,577
Devonshire	2,597.8	437,210
Dorset	977.4	202,092
Durham	1,001.1	833,614
Essex	1,523.2	816,503
Gloucestershire	1,236.8	331,516
Herefordshire	842.0	114,150
Hertfordshire	632.0	258,045
Huntingdonshire	365.6	54,127
Kent	1,520.2	936,003
Lancaster	1,707.7	1,827,390
Leicestershire	819.1	225,896
LINCOLNSHIRE		
Lincolnshire—Holland	410.6	77,583
Kesteven	727.9	103,958
Lindsey	1,501.7	206,497
London	117.0	4,536,063
Middlesex	232.3	792,225
Monmouthshire	539.5	230,800
Norfolk	2,036.7	313,438
Northamptonshire	908.9	207,467
Soke of Peterborough	83.5	41,119
Northumberland	2,009.6	388,059
Nottinghamshire	826.8	274,684
Oxfordshire	743.7	137,118
Rutlandshire	152.0	19,708
Shropshire	1,346.6	239,297

Wales in 10 years of 3,523,191, or 12.15 per cent. The population of the principal cities and towns in England and Wales was as follows: London, 4,536,541; Liverpool, 684,947; Manchester, 543,-930; Birmingham, 522,182; Leeds, 428,953; Sheffield, 380,717; Bristol, 328,836; Bradford, 279,809; West Ham, 267,308; Nottingham, 239,753; Kingston-upon-Hull, 240,618; Salford, 221,015; Newcastle-upon-Tyne, 214,861; Leicester, 211,574; Portsmouth, 189,160; Bolton, 168,025; Cardiff, 163,844; Sunderland, 146,828; Oldham, 137,238; Croydon, 133,885; Blackburn, 127,527; Brighton, 123,478; Preston, 120,860; Norwich, 111,728; Birkenhead, 110,906; Gateshead, 109,891; Plymouth, 107,509; Derby, 105,785; Halifax, 104,997; Southampton, 104,500—all others 100,000 or less. See LIVERPOOL; LONDON; MANCHESTER, etc. For history, government, parliament, political parties, judiciary, local government, education, religion, literature, art, army, navy, foreign relations, finance, banks and banking, commerce, industries, agriculture, fisheries, mining, transportation, etc., see GREAT BRITAIN.

England, Church of, the official name of that body of Christians who have a formal head in the person of the hereditary ruler of England. This designation is used in two senses; first, a general one signifying the Church regarded as continuous, which, from the first triumph of Christianity till now, has been that of the English people; secondly, in a more specific sense, the Protestant Church now established in England as distinguished from the Roman Catholic Church. (See article ENGLAND, *Early Ecclesiastical History.*) The evangelistic zeal of Whitfield, Wesley, and various other clergymen, in the 18th century, awoke the Church to new life, which did not pass away even when the followers of these two great preachers ceased to belong to the English Church. The evangelical party, still the most numerous in the Establishment, is in large measure, the fruit of 18th century revival effort. In the 19th the movement was in other directions. With 1833, just after the passing of the first Reform Bill, the first of a series of 'Tracts for the Times' came forth, and 90 in all were issued within the next eight years. The ritualistic party, at a later date, carried on the work which the tractarians had begun. In 1860 the 'Essays and Reviews,' and in 1862 a work by Bishop Colenso on the Pentateuch, gave prominence to the opposite pole of thought, being what theologians call strongly rationalistic. Church congresses, bringing the representatives of these three parties face to face, softened their antagonisms, and fear of common danger renders them more united than they otherwise would be. In the English Church, at present, there are 2 archbishops and 29 bishops, both of the former and 24 of the latter having seats in the House of Lords; subordinate to these are 30 deans, 82 archdeacons, 613 rural deans, and about 13,500 beneficed clergy, the whole clerical staff of all grades being about 23,000. Including infants, it is believed to have above 13,000,000 adherents in England and Wales. Previous to 1871, the English Church and the Established Church of Ireland constituted but a single body called the United Church of England and Ireland. It is powerful also in the colonies, and by means of its two great societies, the Propagation and the Church Missionary Societies, acts powerfully on nearly every part of the heathen world.

The 39 articles, as the established confession of the English Church, deserve a short analysis. The first five articles contain a profession of faith in the Trinity; the incarnation of Jesus Christ, his descent to hell, and his resurrection; the divinity of the Holy Ghost. The three following relate to the canon of the Scripture. The 8th article declares a belief in the Apostles', Nicene, and Athanasian creeds. The 9th and following articles contain the doctrine of original sin, of justification by faith alone, of predestination, etc. The 19th, 20th and 21st declare the Church to be the assembly of the faithful; that it can decide nothing except by the Scriptures. The 22d rejects the doctrine of purgatory, indulgences, the adoration of images, and the invocation of saints. The 23d decides that only those lawfully called shall preach or administer the sacraments. The 24th requires the liturgy to be in English. The 25th and 26th declare the sacraments effectual signs of grace (though administered by evil men), by which God excites and confirms our faith. They are two: baptism and the Lord's Supper. Baptism, according to the 27th article, is a sign of regeneration, the seal of our adoption, by which faith is confirmed and grace increased. In the Lord's Supper, according to article 28th, the bread is the communion of the body of Christ, the wine the communion of his blood, but only through faith (article 29th); and the communion must be administered in both kinds (article 30th). The 28th article condemns the doctrine of transubstantiation and the elevation and adoration of the host; the 31st rejects the sacrifice of the mass as blasphemous; the 32d permits the marriage of the clergy; the 33d maintains the efficacy of excommunication. The remaining articles relate to the supremacy of the king, the condemnation of Anabaptists, etc. See CHURCH; RITUAL; TRINITY, THE.

Eng'les, William Morrison, American author: b. Philadelphia 12 Oct. 1797; d. Philadelphia 27 Nov. 1867. He was educated at the University of Pennsylvania and became a missionary among the Indians of Wyoming. Later he was pastor of a Presbyterian church in Philadelphia for several years, and in 1838 he was made editor of the output of the Presbyterian Board of Publication, becoming president of the board in 1863. Among his works are: 'Records of the Presbyterian Church' (1840); 'English Martyrology' (1843); 'Sailor's Companion' (1857), and 'Soldiers' Pocket-Book' (1861).

Eng'lewood, N. J., city, in Bergen County, near the Hudson River, on a branch of the Erie Railway; about 13 miles north of Jersey City. It is a beautiful residential city, contains two summer homes for working girls, a hospital, and a library with nearly 10,000 volumes. The mayor holds office for two years. Pop. 6,541.

Englis, John, American ship-builder: b. 1808; d. 1888. He built his first steamers on Lake Erie in 1837. In 1861 he built the Unadilla, the first gunboat built for the United States government. Afterward he built the steamboats St. John, Dean Richmond, Drew, Grand Republic, etc. Many improvements in ship-building were due to him.

English, Earl, American naval officer: b. Crosswicks, N. J., 18 Feb. 1824; d. Washington, D. C., 16 July 1893. He entered the naval service 1840; served in Mexican war; became lieutenant-commander 1862, and served in the Civil War. He was made commodore 1880, and rear-admiral 1884; and retired 1886.

English, George Bethune, American adventurer: b. Cambridge, Mass., 7 March 1787; d. Washington, D. C., 20 Sept. 1828. He studied law and theology, and in 1813 published 'The Grounds of Christianity Examined,' a work in favor of Judaism. In 1820 he served as an officer of artillery in the army of Ismail Pasha against Sennaar, and was afterward United States agent in the Levant, returning home in 1827. He published a 'Narrative of the Expedition to Dongola and Sennaar.'

English, Thomas Dunn, American author: b. Philadelphia, Pa., 29 June 1819; d. Newark, N. J., 1 April 1902. He was graduated in medicine at the University of Pennsylvania in 1839; admitted to the bar in 1842; engaged in journalism in New York in 1844–59; then resumed medical practice in Newark. He was a member of the State assembly in 1863–4, and of Congress in 1891–5. He was the author of 'Ben Bolt,' an exceedingly popular ballad (1843), which after having long fallen into obscurity was revived by its employment in Du Maurier's novel 'Trilby'; 'Walter Woolfe' (1842); 'Ambrose Fecit, or the Peer and the Painter' (1869); 'American Ballads' (1882); 'Book of Battle Lyrics' (1886); 'Jacob Schuyler's Millions' (1886); 'Old Glory,' song (1898); etc.

English, William Hayden, American capitalist: b. Lexington, Ind., 27 Aug. 1822; d. Indianapolis, Ind., 7 Feb. 1896. He was elected to Congress in 1852 and served there through four consecutive terms. As a member of the Committee on Territories, in opposition to his own party, he worked against the admission of Kansas to the Union. He reported from the Committee of Conference what was known as the "English bill," in which it was urged that the question of admission be referred back to the people of Kansas according to the provision of the Lecompton constitution. This was adopted and the people voted against admission. He strongly opposed secession, and warned Southern Congressmen that the North would never countenance such a policy. In 1880 he was the Democratic nominee for Vice-President on the ticket with Gen. Hancock. He published a historical and biographical work on the Constitution and lawmakers of his State and furnished money to the Indiana Historical Society to complete and issue the 'History of Indiana' which he had begun.

English Art. The history of English art embraces four divisions, that is, Architecture, Engraving, Painting and Sculpture.

Architecture.—Numerous so-called Druidical stones, a few rude towers, and some other mysterious structures, are the only remains of the architecture of the ancient Britons. The only monuments of the Roman occupation of the country are the ruins of military works, such as roads and fortified walls that had been executed on a magnificent scale. Very little can be said with regard to the style that prevailed in England between the invasion of the Anglo-Saxons and the Norman Conquest, from the fact that the remains of buildings erected in England before the Conquest are few and insignificant. There was not a single cathedral built before that date but was rebuilt during the Norman period, or at some later time, and although there are traces in numerous churches of pure Saxon architecture, there is no entire church now standing which was built during the Saxon period. There is thus little known about this style beyond the fact that it was a variety of Gothic, probably rather rude. The Normans introduced a more highly developed kind of Gothic, the style in which most of the English cathedrals are built. The earlier specimens of this style of architecture in England, such as may be seen in parts of the cathedrals of Rochester, Winchester, and Canterbury, naturally exhibit no distinctively English features, but resemble on all points the works executed in the same style on the Continent. It was not till the beginning of the 12th century that the new architecture began to assume a character of its own peculiar to England. Durham Cathedral affords the best illustration of this style. The ogive or pointed arch appears to have been introduced into English architecture in the second half of the 12th century, and the first traces of its use are to be found in the cathedrals of Canterbury, Rochester, and Northampton. This new modification of Gothic architecture soon made way for itself, although it appears to have been adopted with some reluctance in England. In the end it became the prevailing and even the sole style of ecclesiastical architecture in England, the round arch being entirely disused for three centuries. Among the edifices erected in this style between the 12th and 15th centuries may be mentioned the cathedrals of York, Wells, Winchester, Lichfield, Worcester, Chichester, Lincoln, Westminster, etc. The most characteristic peculiarity of Gothic architecture in England, after the introduction of the pointed arch, consists in the form of the windows in which the mullions rise right up to the main arch of the window, and are often crossed by horizontal bars. This peculiarity has caused the name of perpendicular to be given to the style of architecture in which it is found. The Tower of London, Windsor Palace and the great hall of the palace of Edward III. are the finest specimens of military and civil architecture belonging to the same period as the religious edifices above-mentioned. The Renaissance style of architecture made its appearance under the Tudors, and was associated with the Gothic. The palaces of Richmond and Hampton Court, the chapel of Henry VIII., and the tombs of Queen Mary and Queen Elizabeth at Westminster, Bishop West's chapel in the cathedral of Ely, and the six coffins placed by Bishop Fox around the choir of the cathedral of Winchester, are the principal examples of this mixed style, in which are wanting both the elegance in details and the capricious fancy which distinguish the productions of continental art during the same epoch. In the reign of Charles I. Inigo Jones designed, among other buildings, St. Paul's at Covent Garden and Greenwich Hospital in a peculiar style, imitating the Græco-Roman. Architecture, neglected under the Commonwealth, revived after the Restoration, when Sir Christopher Wren designed an immense number of buildings, particularly St. Paul's Cathedral at London, the towers of Westminster, the Sheldonian theatre of Oxford, Chelsea Hospital, etc. Other architects of his time were not less productive. Among them are Gibbs, and Sir John Vanbrugh. In the 18th century the style of Louis XV. prevailed in England. The most celebrated architects of the time were W. Chambers and Robert Taylor. At the present day English architects are in the habit of copying indifferently from all styles, and sometimes even mix up different styles in the most monstrous fashion. The most striking novelty in architecture in the 19th century is the method of building in glass and iron, first resorted to on an extensive scale by Sir Joseph Paxton in the International Exhibition of 1851, and subsequently adopted in the Crystal Palace and various other structures. See ARCHITECTURE.

Engraving.—Until the 18th century engraving was not cultivated at all in Great Britain except by foreign artists. The German engraver, Wenzel Hollar (d. 1677), was the most distinguished engraver in England in the 17th century. Alongside of the national school of painters, created in the 18th century by Hogarth, Gainsborough, and Reynolds, there arose almost simultaneously an English school of engravers. Hogarth himself acquired some distinction in the art of engraving; but those who were more specially devoted to this branch of art were George Vertue (1684–1756, celebrated especially for portraits), Sir Robert Strange — a Scot (1721–92), Valentine Green (1739–1813), and Richard Earlom (1743-1822). The last two were mezzotint engravers, and carried this branch of the art to a high degree of excellence. The most celebrated line-engravers in the period immediately subsequent to that during which those just mentioned lived were William Sharp (1749–1824), James and Charles Heath (the former died 1834, the latter 1848), and James Fittler (1756–1835). At this period many small plates were produced as illustrations for books. Toward the end of the 18th century the stipple style of engraving was introduced by the Italian Bartolozzi, and since that period it has been followed by a good many English engravers. In 1775 Thomas Bewick (1753–1828) revived engraving on wood, a style which has since been very extensively resorted to for the illustration of periodicals and other works. The most distinguished of his followers were his pupil Clennell, Branston, and John Thompson. Among other English engravers on copper or steel we may enumerate George Doo, John Burnet of Scotland, Samuel Cousins, William Holl, Edward Goodall, and John H. Robinson. In steel engraving English artists have manifested a decided superiority over those of other countries. In lithography, too, some of the English artists have displayed genuine talent. Among the best works which have appeared in this department may be mentioned the collections of architectural views of England and Belgium by Haghe and Nash. See ENGRAVING.

Painting.—Very little is known of the state of the art of painting among the Anglo-Saxons. In the 7th century, Biscop, abbot of Wearmouth, brought from Italy a large number of pictures with which he adorned the churches dependent upon his monastery. In the 9th century Alfred the Great, with the view of refining his war-like subjects, caused numerous manuscripts to be made and adorned with miniatures. Toward the end of the 10th century, Dunstan, archbishop of Canterbury, had the reputation of being an expert miniature painter, and some of his illuminations are preserved in the Bodleian Library at Oxford. Under the reign of William the Conqueror, and those of his two sons, the painting of large pictures began to be studied. Lanfranc, archbishop of Canterbury, a native of Lombardy, one of the most renowned men of letters of his time, adorned the vault of his church with paintings of ravishing beauty, to use the expression of a chronicle of the period. Numerous miniatures of the 13th and 14th centuries have come down to us; the execution is rude, but the style does not want originality. From this period down to the 18th century there were few native painters, and scarcely any of importance in England. A succession of foreign painters were attracted to the country by the munificence of some of the English sovereigns, and of the English aristocracy, but no native talent was developed in this direction. Among these foreign painters connected with England may be mentioned Hans Holbein, a German painter, who enjoyed the favor of Henry VIII.; Federigo Zuccaro, an Italian, who came to England in the reign of Queen Elizabeth, and painted at her court; and Sir Anthony VanDyck, the great Flemish portrait-painter, who lived at the court of Charles I. There is one native English painter deserving of mention who appeared before the close of the 17th century, although even his chief works belong to the 18th. This was Sir James Thornhill (1676–1734), the painter of the cupola of St. Paul's in London, and of the Painted Hall in Greenwich Hospital. The period of the decline of the art on the Continent was the time when England attained her highest eminence in it. When there was no longer any art in Italy, Spain, Germany, Flanders, and Holland, and when France alone of continental countries possessed some painters of lively fancy, there suddenly appeared in London a painter of original and consummate genius, who may almost be said to have created a new kind of painting, in which the artist exhibited the qualities of a moralist and satirist combined with those of the painter; and he was closely followed by two portrait-painters, whose portraits rivaled, in point of elegance, those of VanDyck. The first of these was William Hogarth (1697–1764); the two latter, Sir Joshua Reynolds (1723–92), and Thomas Gainsborough (1727–88). Gainsborough was a distinguished landscape- as well as a portrait-painter. Throughout the 18th century portrait-painting was the most brilliant specialty of the English school. At the same time that Reynolds and Gainsborough flourished there lived also George Romney (1734–1802), who almost equaled them in excellence, and a little later Sir Henry Raeburn (1756–1823), a painter endowed with some share of the vigor of Velasquez, and Sir Thomas Lawrence (1769–1830), who attained more nearly than any other painter to the elegance of style of Sir Joshua Reynolds. He succeeded Sir Joshua in 1792 as court-painter. Barry, Opie, and Copley, the last an American, are among those who manifested more talent in the painting of simple portraits than in the historical composition which they attempted. There also flourished during this century Richard Wilson (1713 or 1714–82), a Welsh landscape-painter in the style of Claude and Poussin, and Benjamin West (1738–1820), an historical painter, who, though American by birth, deserves to be mentioned here from the fact of his having come early to England, and having been connected with England during the most of his life. Hogarth had no immediate successor in the painting of familiar scenes of daily life. This kind of painting was revived with great effect at the beginning of the 19th century by Sir David Wilkie (1785-1841), one of the most popular and highly esteemed of British artists, He made his first appearance at the Academy Exhibition of 1806 with his 'Village Politicians.' Among the painters who have followed in the footsteps of Wilkie may be mentioned William Mulready (1786-1863), Charles Robert Leslie (1794-1859); Daniel Maclise (1811-70); John Phillip (1817-67); William Powell Frith (b. 1819); Thomas Faed (1826-1900); William Holman Hunt (b. 1827); and Sir John Everett Millais (1829-96). The last two were among the founders of the pre-Raphaelite school of painters, the distinguishing characteristic of which is extreme fidelity in matters of detail. The chief historical painters of the 19th century include William Etty (1787-1849), and Benjamin Robert Haydon (1786-1846); by far the most celebrated landscape painter is Joseph Mallord William Turner (1775-1851); and Sir Edwin Landseer (1803-73) is the most distinguished animal-painter that Great Britain ever produced. Water-color painters have been very numerous and successful in England; among them are Corbould, Cattermole, Haghe, Wehnert, Prout and Gilbert (also an oil-painter). See ART; HOGARTH; PAINTING; etc.

Sculpture.—Cæsar records that the ancient Britons were fond of cutting out ornaments of various kinds on their chariots of war, but that they were entirely ignorant of the art of casting statues in metal, or cutting them in stone. The ivory drinking-horn of Ulfus, preserved at York, is one of the few specimens of carving that has come down to us from the time of the Anglo-Saxons. After the Norman Conquest the arts of carving and sculpturing were practised almost wholly by foreign artists, Frenchmen and Italians, and it was not till the 13th century that some remarkable works began to be produced by native artists. At this epoch, however, the arts of carving and sculpture were still regarded merely as handmaids to architecture. These arts received a check during the wars of the Roses, and were not again cultivated till the Renaissance period, when Torregiano came from Italy and executed two masterpieces in England, the tomb of the mother of Henry VII., and that of Henry himself, at Westminster. The troubles of the reign of Charles I. and the Commonwealth produced a new stagnation in the art; and what is more to be regretted, were the cause of the destruction of many valuable works of art in this department. After the Restoration two sculptors of some note appeared in England, Grinling Gibbons, a wood-carver, born at Rotterdam, and Caius Gabriel Cibber, who, though ridiculed by Pope, was a man of real talent. During the 18th century there was no English sculptor of eminence till John Flaxman (1755-1826) appeared to resist the false taste of the time. His monument to Lord Mansfield, and his statues to Pitt and Reynolds, are among the finest productions of English sculpture. He had for rival and successor Sir Francis Chantrey (1781-1841), who acquired renown by the statues which he made of most of the eminent men of his time. John Carew, Lawrence Macdonald, Sir Richard Westmacott (1775-1856), Edward Hodges Bailey (1788-1867), and John Gibson (1790-1866), are a few of the sculptors of the earlier half of the 19th century, to whom we should not forget to add J. H. Foley, W. C. Marshall, P. McDowell, Sir John Steell, and H. Weekes, as among the first sculptors of their time. See SCULPTURE.

English Channel, or **The Channel** (Rom. *Oceanus Britannicus*), an arm of the Atlantic Ocean extending into the west coast of Europe to the Strait of Dover, by which it is connected with the North Sea. The land bodies separated by this channel are England and France. Its length from the Strait of Dover to the Atlantic Ocean is 280 miles; its greatest breadth, from Saint Malo, in France, to Sidmouth, in England, is 140 miles; area 30,000 square miles. The length of the north coastal line, from Land's End to Dover, is 390 miles; and of the south coastal line is 570 miles. Some of the largest indentations on the coast of England are the bays of Falmouth, Plymouth, Lyme, Weymouth and The Solent. On the coast of France are Baie de la Seine and Baie de Mont St. Michel. The principal islands in the Channel are: Isle of Wight, Channel Islands, and several other islands near the coast of France; Scilly Isles and Ushant at the entrance.

English Chronicles. The writing of English chronicles begins with the 'Anglo-Saxon Chronicle,' the earliest English history written in the English language, and the earliest vernacular record of national events in modern Europe. The 'Chronicle' opens with the Christian era, combining in its earlier parts records of Roman, Christian, and British events. It rapidly becomes strictly national, carrying the record of English history forward to a considerable period after the Norman Conquest. It treats in general of the affairs of all the English-speaking peoples in Great Britain, and as one of the first attempts at an expression of coherent national life and as a trustworthy source of information concerning the language, history, and social manners and customs of the Anglo-Saxon period, the importance of the 'Chronicle' can hardly be over-estimated. Although the work itself does not mention the name of its author, there is strong evidence to show that in its original form it was undertaken at the suggestion of King Alfred and was in part actually written by him. From this original form, now no longer extant, copies were made and carried to different sections of England, where they served as foundations of what, from that time, became separate and independent chronicles. Seven of these local chronicles, with a fragment of an eighth, have come down to us. The date at which the original parent version was made was about 892, and the place was probably Winchester, the capital of the West-Saxon kingdom. The form in which the 'Chronicle' is written is that of a book of annals, the entry for each year containing usually the record of but a single occurrence. For the early years the records, derived chiefly from literary sources, are brief and colorless, but in the later parts, particularly in the accounts of the Danish wars, when the narrative becomes more nearly contemporary with the time of the compilation of the work, they become more detailed and vigorous. At no time, however, is there an attempt to write a philosophic history, to point out the causes or the trend of events. This is in accord with the main purpose of chronicle writing, which is merely to keep the events of history in their right chronological perspective, the details centering about these events being largely entrusted to oral tradition. This annalistic purpose of the 'Chronicle' determined also its mechanical form. The scribe's method was to rule off a number of pages as though preparing a journal in which the entries were to be made by years instead of days. Each year was thus given a blank space opposite its number sufficient usually for only a few lines. The scribe then inserted whatever annals he had been able to collect, leaving the spaces for which he had no materials to be filled in later when new material should become available. This method of chronicle writing remained long in use in England, being followed by Capgrave as late as the 15th century.

Although no single model or source for the 'Chronicle' is known, there were in existence in Alfred's time a number of Latin works which were of help on its original compilation. Of these the most important were Bede's 'Historia Ecclesiastica Gentis Anglorum,' finished in 731; Bede's 'De temporum ratione,' a chronological essay containing a short epitome of the history of the world from Adam to 729 A.D.; Orosius' 'Universal History' ('Pauli Orosii Historiarum Adversum Paganos Libri VII.'); and doubtless many records of national events preserved in local monastic libraries. But the 'Chronicle' was an original work in that it strove to record the life of a nation. Just as the codes of laws systematized the customs and rules of living of the people, so the 'Chronicle' fixed for them the ever-receding events of this history.

From the period of its original composition to the middle of the 11th century, the 'Anglo-Saxon Chronicle' established the form for all historical writing in England. Although we now know only seven, with the fragmentary eighth, versions of the 'Chronicle,' the number in the Anglo-Saxon period must have been much greater, copies being probably kept at every important monastery and town. Towards the end of the Anglo-Saxon period, however, the 'Chronicle' tends to become less and less national, and more and more ecclesiastical in its character. In harmony with this change, the language of chronicle writing changed also to Latin. The use of Anglo-Saxon as late as 1154, the date of the latest entry in that tongue, appears only in one version, and is plainly due to reasons of respect for the traditional language of the 'Chronicle.' To take the place of the English annals of the 'Chronicle,' new histories began to be written in Latin. The earliest of these was that of Ethelwerd; others from the beginning of the 12th to the 14th century were the histories of Symeon of Durham, Florence of Worcester, William of Malmesbury, Henry of Huntingdon, Roger of Hoveden, Matthew of Paris, Matthew of Westminster, Roger of Wendover, and Ralph Higden, whose 'Polychronicon' was the "standard work of general history in the 14th and 15th centuries" (Babington, ed. of 'Higden' in 'Roll's Series,' p. xliii.). All of these Latin histories derived much of their material either directly or indirectly from the Anglo-Saxon Chronicle. In the Middle English period, several metrical histories were written in English, the 'Brut' of Layamon, the chronicles of Robert of Gloucester, and of Robert Manning of Brunne; but these are better characterized as historical romances than as attempts at veracious history. The writing of prose histories in English begins again with Trevisa's translation of Higden's 'Polychronicon,' made in 1387, and with John Capgrave's original chronicle, written about the middle of the following century. The tone of Capgrave's work, as compared with the Anglo-Saxon Chronicle, is extremely naïve. The writers of the Chronicle had a most rigid sense of historical fact, but the work of Capgrave and his contemporaries is marked by an altogether uncritical and credulous mingling of legend and history. As a result, however, of this infusion of the romantic spirit into historical writing, the older annalistic method gave way to one in which greater attention was paid to a consecutive narrative interest, after the manner of modern historical writing. The national awakening accompanying the reigns of Henry VIII. and Elizabeth resulted in a renewed interest in the writing of these history-chronicles. In 1516 appeared Fabyan's 'New Chronicles of England and France'; in 1562 Grafton's 'Abridgment of the Chronicles of England'; in 1565 Stowe's 'Summarie of Englyshe Chronicles'; and in 1578, the most important of the Elizabethan chronicles because of the use made of it by Shakespeare, 'The Chronicles of England, Scotland, and Ireland,' written by Holinshed with the assistance of several others. The term chronicle continued to be used in the titles of historical works to the end of the 17th century, as in Sir Roger de Coverley's favorite book, Baker's 'Chronicle of the Kings of England,' 1643; by this time, however, the naïve annalistic chronicle had largely given way to the more philosophical treatment of events which is designated by the name of history.

Bibliography.—For general bibliography, consult Gross, 'Sources and Literature of English History from the Earliest Times to about 1485' (1900). Editions of most of the chronicles will be found in the Great Britain Rolls Series; the best edition of the Anglo-Saxon Chronicle is that of Earle and Plummer (Oxford 1892-1899). The literary significance of the chronicles is discussed by Schofield, 'English Literature from the Norman Conquest to Chaucer' (pp. 29-46); and by Schelling, 'English Chronicle Plays' (New York 1902).

GEORGE P. KRAPP,
Instructor in English, Columbia University.

English College at Rome, an ancient institute in the papal city, founded, according to mediæval chroniclers, about 816, for in that year the *angelcynes scolu*, school of the English nation, was destroyed by fire. Built anew, it had a like fate twice in that century. Thomas à Becket, archbishop of Canterbury, was lodged in the hostel when he visited Rome. Shortly after the murder of the archbishop and his canonization the church adjoining the college was called by his name. Later the hostel connected with the college was abandoned, and in 1380 a new hostel was built and liberally endowed, chiefly by rich London merchants, for free entertainment of Englishmen visiting the Holy See. In the time of Henry VIII. refugees from England were harbored in the hostel. In the reign of Elizabeth the institution was transformed into a seminary for the education of aspirants to the priesthood who proposed to serve in the English mission, which they entered with pretty fair assurance of the martyr's crown. Between 1578 and 1647, 40 of the alumni of the institution, serving as missionary priests in England, were executed for the high treason of exercising the Catholic ministry contrary to the laws of the realm; and when St. Philip Neri, founder of the Congregation of the Oratorians, met any of the young English ecclesiastics in the streets of Rome, his invariable salutation was *Avete flores martyrum* — "Hail flower of the martyrs." The college was plundered and wrecked by the French republican army 1798 and its resources dissipated; it was resuscitated 1818; its president from 1831 to 1846 was Nicholas Wiseman, afterward first archbishop of Westminster, and cardinal.

English Harbor, a harbor on the southern coast of Antigua, one of the Leeward Islands. It is the site of a British naval station, which from its location is one of the important British possessions of the West Indies.

English Language. The English language is a direct development of the Anglo-Saxon, a circumstance which makes it questionable whether the latter speech ought to be distinguished by a separate name. But although a direct development of the Anglo-Saxon, it is not a development which has been allowed to take place regularly and gradually, as the result merely of internal causes. One important external influence was brought to bear on the original form of our language, which had the double effect, first, of producing a much more sudden and complete modification of the grammatical structure than could have taken place if the language had grown up independently of foreign influences; and secondly, of giving a composite character to the vocabulary of the language by the introduction of a large number of foreign words. This external influence was the Norman Conquest, in consequence of which a new language, the Norman-French, came to be spoken in England by those who had made themselves the masters of the country, and who formed, therefore, almost the only class that had leisure and opportunity for literary pursuits. The immediate result of the Norman Conquest (1066) was thus that the language of the Normans came to be the chief literary language of England (except where Latin was used), and that the Anglo-Saxon was reduced to a very subordinate place. When the latter language again comes into notice as a written language, a great change is seen to have been wrought in it. Before the Conquest it was a very highly inflected, or what is called a synthetic language, that is, one in which the substantives, adjectives, verbs, and articles are subject to numerous modifications, each of which expresses a modification of the root-meaning of the word, or shows the relation of the word to the other words in the sentence. During the period when Anglo-Saxon ceased to a great extent to be a written language these inflections dropped off; and when it re-emerges as a written language about the end of the 12th century, it is no longer synthetic, but analytic, that is, prepositions and auxiliaries are now used instead of inflectional prefixes and terminations to express the various modifications of the idea contained in any word, and the relations of the words in a sentence to one another. At this period, however, the language still continued to be essentially homogeneous in respect of its vocabulary: the Norman words that occur are so rare that they need not be taken into account. And it was natural that it should be so, for the Saxon language was still confined to the Saxon inhabitants of the country; and those who wrote in it addressed themselves only to that portion of the community, and accordingly had no occasion to use any word of Norman origin. This state of matters lasted till about the middle of the 13th century, which is the period at which English proper is usually regarded as having begun to be spoken and written. By this time the Normans began to experience the inconvenience of not being acquainted with the language of the people among whom they dwelt, and in learning to speak and write it they very naturally used a large number of Norman words, and these words were adopted by all such writers belonging to the subject race as wished to make themselves understood by Norman as well as by Saxon readers. A very rapid mixing of the two languages thus took place, and a second important change was wrought in the English language. It is no longer homogeneous in its vocabulary, but contains a large admixture of foreign words. The whole of what precedes may be shortly summarized thus: — From 450 to 1066 the language spoken in England was the so-called Anglo-Saxon, a dialect of Low German, very highly inflected. From 1066 to 1250 two languages were spoken in England, Anglo-Saxon and Norman-French, by two different sections of the population occupying different political positions. During this period the grammatical structure of the former language began to be broken up, chiefly owing to its being disused for literary purposes; and toward the end of the period we find a few works written in a language resembling the English of our day in grammar, but differing from it by the homogeneousness of its vocabulary. Finally, about 1250 the two languages begin to mingle, and form one intelligible to the whole population, Normans as well as Saxons. This is what is usually called English proper. English is thus seen to be a composite language, deriving part of its stock of words from a German source, and part from a Latin source, Norman-French being in the main merely a modified form of Latin. The changes that have taken place in the English language subsequently to 1250 are by no means as striking as those which took place in the transitional period between 1066 and 1250. Some few inflections which the English of the 13th and 14th centuries still retained have now been dropped, but the chief change which the language has experienced consists in its gradual growth and expansion in obedience to the requirements of advancing science, more complicated social relations, and increased subtlety of thought. This growth has been going on at all times, but there are some periods which may be pointed out as more remarkable than others for the rapidity with which it proceeded. Such a period was the end of the 16th and the beginning of the 17th century, the period of the Reformation and following the revival of learning, when numerous words of Latin origin were introduced by scholars directly from that language, instead of through the French, the channel through which most of the Latin words previously found in the language had come. Another such period is the present, when the rapid growth of the sciences already existing, and the creation of new sciences, have caused whole groups of words to be introduced, chiefly from the Greek.

It would scarcely be in place here to discuss the various excellencies and defects of the English as compared with other languages, but we may mention the following as among the qualities which the English language is generally allowed to possess. 1. Strength and expressiveness, adapting it admirably for poetical composition. 2. Copiousness. In connection with this may be noted the extraordinary receptivity of the language, that is, its capacity for adopting new words from all sources, and of naturalizing them at once, so that they may be treated without any appearance of strangeness entirely as native English words. 3. Simplicity in form and construction. 4. Great flexibility, or adaptability to all kinds of composition, the grave and gay, the impassioned and calm, forcible and tender, sublime and ludicrous.

In connection with the subject of the English language, we may here further observe, that England and the United States offer the first instance in history of two great, independent, and active nations having a common language, but situated at a great distance from each other, and daily developing new and characteristic features. These relations must, sooner or later, exert a powerful influence upon the common language, for no language is so stable as not to undergo continual changes, if spoken by a people in the full vigor of social and political life. This state of things has already produced some effect on the English language. The most material difference, probably, has been in the pronunciation of the language, which, however, important in our daily conversation, is of secondary importance in relation to the literature and written language of the two countries. It has often been observed by English travelers and others that the pronunciation of the United States is far more uniform than that of England; and so nearly alike everywhere, that the people of any one town or district are perfectly understood in every other part of the country, which is not true of the lower ranks of England. When considered more minutely, however, there has for a long time existed a marked distinction between the pronunciation of the New England and Southern States. The orthography of the English language has undergone no material change in America, it being the general inclination to follow that of the best English writers of the age.

The English language may be divided into five periods:

1. First Period 450-1100 A.D.
2. Second Period 1100-1250 A.D.
3. Third Period 1250-1350 A.D.
4. Fourth Period 1350-1460 A.D.
5. Fifth Period 1460 A.D.—the present day.

In the first period (called also Anglo-Saxon or Old English), the language was inflectional; in the second it began to show a tendency to become analytic, the tendency increasing till in the fourth period inflections had virtually disappeared. Before the Norman Conquest there were two dialects in English, a southern and a northern, the former of which was the literary language. After the Conquest dialects became much more marked, so that we can distinguish three great varieties, the northern, the midland, and the southern, distinguished from each other by various grammatical differences. The midland dialect was that most widely spread, and it ultimately became the standard language, a result principally due to the influence of Chaucer, and in a less degree of Wyclif, Gower, and others. See DIALECT; SCIENCE OF LANGUAGE.

English Literature. The Norman conquest made a great change in the development of an English literature, as in all other departments of English life. Conditions were at first most unfavorable: the English language might be used by any who pleased, but the clergy naturally used Latin, and people of any position, French, or Anglo-Norman, as it is commonly called. For three centuries, therefore, we do not find in English any striking original work, anything to compare in interest with the Skaldic poetry and the Sagas in Iceland, with the French romances and fabliaux, with the German epic and courtly poetry. During these centuries, however, we do find in England what is in its way most interesting, namely, a singularly rich representation of the different phases of mediæval thought. We may conveniently begin with the work connected with the older order of things. The Anglo-Saxon Chronicle was still kept up at Worcester and at Peterborough. Of these the former is preserved only as far as 1079; the latter is a much later work; in 1121 the whole chronicle was rewritten and then carried on to 1154, being something more than a mere set of annals, with a distinct character of its own. After this, beginning indeed before, comes a stately series of Latin chronicles, but in English we find only chronicles in verse. Layamon's 'Brut,' (c. 1200, after the Anglo-Norman of Wace, which itself is a paraphrase of Geoffrey of Monmouth) is most interesting as language, literature, and legend, giving, among other things, the introduction of King Arthur to English readers. Much later are the chronicles of Robert of Gloucester (c. 1300) and Robert of Brunne (1330). Layamon is hardly as much history as romance. Of this latter almost everything is from French, Scandinavian or Celtic sources: there is little native English either in form or substance. 'King Horn' (c. 1250) and 'Havelock the Dane' (c. 1275) probably go back to Scandinavian originals, though they are still regarded by some as English legend material: more purely national are the stories of 'Bevis of Hampton' (c. 1275) and of 'Guy of Warwick' (c. 1300), though the versions preserved are probably from Anglo-Norman originals. Renderings of Continental romances are numberless, beginning about 1250 with the Alexander story and going on with the tale of Troy, the stories of King Arthur, the Round Table, and the Holy Grail, where the material is partly Celtic, giving even somewhat of the legends of Charlemagne, and many minor stories, as 'Floris and Blancheflor,' 'Amis and Amilon,' 'Sir Tristram.' Somewhat later (1300), and less fully, come versions of the fabliau, 'Dame Siriz,' 'Reynard the Fox,' the 'Land of Cokayne,' the 'Lay of the Ash.' About this time appear the great mediæval collections of stories, the 'Seven Sages' and the 'Gesta Romanorum,' which latter, though in Latin, was collected in England. Besides all this epic and narrative material there is a smaller lyric element: oftenest anonymous, like 'Sumer is ycumen in,' (c. 1250), 'Winter wakeneth all my care,' and other love songs, as well as many political songs, among which are the patriotic poems of Lawrence Minot (c. 1325). But generally where it is not narrative, the Middle English poetry is didactic: the so-called Proverbs of Alfred, dating from the twelfth century and preserved in several versions, may have old material and certainly keep something of the old alliterative form, though there is also the Norman element of verse. And as the Anglo-Saxon priestly writers used alliteration in their didactic prose, so now much of the religious literature is put into rhyme, a fashion of the Norman. The 'Poema Morale' (1200) is a sermon in verse, though now and then with a personal element, and there are many more shorter homilies. A common form is the dialogue; the 'Debate of the Body and the Soul' is known in various forms (1200 and after), the dialogue between 'Mary and the Cross,' and others including, in lighter mood from a French source, the 'Owl and the Nightingale' (1220), a poem full of popular wisdom in which the gay and the gloomy views of life are championed respectively by the two birds who refer the dispute to Master Nicholas of Guilford, generally taken as the author. Less original in substance are the versions of Scripture of which the 'Ormulum,' a metrical paraphrase of the Gospels by Orm of Lincolnshire (1220) is most important for linguistic reasons, preserved in an autograph copy (probably) with an individual system of phonetic spelling. Versions of Genesis and Exodus (c. 1225) are also to be mentioned, while much later in the north (1320) 'Cursor Mundi' reviews the whole extent of history from the creation to the day of judgment. Lives of the saints there were also, especially of Saints Katherine, Margaret, and Juliana, and much devotional poetry, some lyric, like the 'Wohung of oure Loverde' (c. 1225), and others, some didactic, like 'Hali Meidenheid' (c. 1250). There are also certain larger religious treatises: the 'Ancien Riwle' (1225), a prose work of considerable merit, giving the conditions of convent rule, and in the early part of the fourteenth century, three books on holy living, the 'Prick of Conscience,' by Richard Rolle of Hampole; the 'Ayenbite of Inwit,' by Dan Michael of Northgate, and 'Handlyng Synne,' by Robert of Brunne, the two latter from the French. Also to be noted is the very characteristic 'Bestiary' (1225), a compilation of the mediæval speculation on natural history. Such are the main elements of Middle English literature before 1350, although the number of particular works is far greater. As is common in mediæval literature the language is dialectic: no one dialect gains entire primacy till much later, although by this time the East Midland has become the most important. The second half of the fourteenth century was a period of great literary activity. England had been long separate from Normandy, and the English language, like the English people, had digested its different elements into an organic combination. Literature now becomes more literary. The old forms were now only to some degree preserved: Trevisa translated the 'Polychronicon' of Higden (c. 1387); Barbour in the north wrote a rhymed chronicle of Bruce (c. 1375). There are numbers of romances from the French. But didactic or allegoric poetry appears in forms which, though not new, have yet a certain original character. There are two great poets: one of name unknown, the author of the 'Pearl,' 'Gawain and the Green Knight,' 'Cleanness,' and 'Patience,' the other William Langland (as is most commonly thought), the author of the 'Vision Concerning Piers the Ploughman.' Fine as is their work, it is outshone by the genius of Chaucer, who gathered up and summarized the spirit of the century and whose influence was carried through the century following by companions or followers of whom the most noteworthy were Gower, Hoccleve, and Lydgate. The epoch was also illuminated by Wiclif's great translation of the Bible (c. 1382). Two more popular forms of literature must be mentioned, as beginning lines of literary development still important. The ballads of Robin Hood probably go back to this period, while many of the Scotch ballads are older. The four cycles of mystery plays, those of Coventry, Chester, Wakefield (Towneley plays) and York, belong to the earlier part of the century. One remarkable book comes in no category, the 'Voiage and Travaile of Sir John Mandeville,' widely spread in England, and, though a translation, a monument of noteworthy prose. The 15th century was a period of bloody civil strife, and in literature a period of great dearth. Little can be mentioned in a summary. Sir Thomas Malory closed the period of the romances of chivalry by the 'Mort Darthur' (c. 1475), a collection to which he gave organic form and unity. The book was first printed (1585) at the press of Caxton, himself a writer and compiler. Some prose treatises are noteworthy, in religion Pecocke's 'Repressour of too much overblaming of the Clergy' (c. 1450); in politics, Fortescue's 'Monarchy,' (c. 1425), while of lighter interest is the treatise on 'Hawking' by Dame Juliana Berners (c. 1425), and the every-day Paston Letters which belong to literature because they are so interesting.

With the 16th century new influences become powerful. The revival of classic learning stimulated English scholars under the leadership of Grocyn, Linacre, Colet, Cheke. The ideas of the reformation stirred up clouds of controversy in which appear the great figures of Tyndale, Latimer, Coverdale. The spirit of nationality was aroused and More ('Utopia,' 1515), and Elyot (Governour, 1531), thought deeply on questions of politics. These men wrote not so much for literary reasons as for some particular purpose: later came the impulse of the Renaissance which brought forth in England a wonderful burst of literature, generally included in the age of Elizabeth. Most important was its manifestation in the drama. To the mystery plays had succeeded miracle plays, and then moral interludes, and imitations and translations from Seneca and Terence. By the latter half of the century appeared the first specimens of modern drama, 'Ralph Roister Doister,' by Nicholas Udall (1550) and 'Gorbuduc,' later called 'Ferrex and Porrex,' by Sackville and Norton (1569). The Theatre was built in 1579, the Curtain not long afterward, and in the last decade of the century the Rose, the Globe, the Fortune and others. The theatre of the day demanded a drama rich in poetry, rhetoric, declamation, and action. The first group of dramatists, Lyly, Peele, Kyd, Greene, and greatest of them, Marlowe, were all of necessity experimentalists. They created the romantic drama, with tragedy, comedy, history, into which Shakespeare poured his inexhaustible stores of imagination, observation, and wisdom. His plays are typical of the Elizabethan drama: there is little in the other dramatists that you cannot find in him. Yet there were others of great power. Ben Jonson is usually accorded second place, and Beaumont and Fletcher, Marston, Middleton, Heywood, Chapman, Massinger, Ford and Shirley, beside others, have each special powers, although a decline occurs and in 1642 the theatres were closed by order of Parliament and a great dramatic tradition came to an end. One later form deserves special mention: the masque was originally a form of private theatrical and always remained distinct from the plays presented at the public theatres. It was produced for some special great occasion and employed all the possibilities of the day in scenery and costume, music and dancing. The words were often written by dramatists of great ability, notably by Ben Jonson. The most famous and beautiful masque was written at the end of the period, the 'Comus' of John Milton. In lyric poetry as well as in dramatic was the age pre-eminent. In the reign of Henry VIII., Wyatt and Surrey had led the way, though under the influence of Italy, in 1557 appeared Tottel's 'Miscellany,' an anthology which gathered up the verse of preceding years, and some years afterward came another, the 'Paradise of Dainty Delights.' Later collections are the 'Bower of Delights,' 1591; 'The Phœnix' Nest,' 1593; 'The Passionate Pilgrim,' 1599; 'England's Helicon,' 1600. Another characteristic production was the sonnet-sequence, of which Sidney's 'Astrophel and Stella' (1591, but written before), is one of the best and earliest examples. Here belong the famous sonnets of Shakespeare, as well as Daniel's 'Delia' (1592), Drayton's 'Idea' (1593), Spenser's 'Amoretti' (1595), among a host of others. One great lyric poet is pre-eminent, John Donne, whose poems, written in his earlier years, had immense influence. This form of the lyric is in the imitations fanciful and finespun, but in Donne himself it is alive and wonderful. Last among the lyrics and as important as anything else are the songs. Music had an important place in English life, and where there was so much singing, there needed to be good songs. There appeared great numbers, some in the plays and others in song-books, of which many still exist. A good many are translations and more are very slight, but Shakespeare's and Jonson's among the dramatists, and Campion's among the song-writers, are worthy a high place in any anthology. In the seventeenth century, while the drama lost power, the lyric sustained itself remarkably, though in the hands of fewer artists. They are generally followers in well-known lines, the paths of Spenser, of Jonson, of Donne, but they often produced work quite equal to their masters. The early poems of Milton, the exquisite 'Hesperides' (1647) of Herrick, the courtly and amatory poetry of Carew, Suckling, Lovelace, the religious poetry, passionate and almost sensuous in Crashaw, earnest and devoted in Herbert, these show no failure in power or in genius. One great name in Elizabethan poetry is still to be mentioned, that of Spenser. The 'Amoretti' are as beautiful as any of the sonnet cycles, the 'Shepherd's Calendar' (1579) was an immense influence for a long time, but his great title to fame is the 'Faerie Queene' (1590–96), a work which in literary form stands a little apart from its time. It is a romantic epic, akin to the Italian poetry of the preceding century, but Spenser's own, in its high idealism, its pictorial quality, and its mastery of poetic expression. It had imitations and followers, but none of great merit. It is well-nigh impossible to bring the prose of this period under any series of heads. Poetry always comes first in literary development: in the 16th century prose was commonly written for some practical purpose. It is true there was some growth of style: many men labored at improving the vocabulary and elaborating the sentence-structure and the resources in figure and ornament. Yet there were hardly any well-established prose-forms: the 'Arcadia' (1580–90) of Sidney, the 'Ecclesiastical Polity' (1592–7) of Hooker, the Essays (1597) of Bacon, are of widely differing kind and provoked little following. Even Lyly's 'Euphues' (1578–79) which was immensely imitated for a decade, produced no permanent form. The pamphlet or the tract is the one characteristic Elizabethan production: its master was Tom Nash, who poured forth numbers of these ephemeral pieces, of wonderful vigor and spirit. Of the same sort of prose the succeeding century showed much. The reign of Elizabeth had been a time for Englishmen to get together and establish their position against the world. Having made themselves a place, they turned to put in order their own house: the 17th century is a period of civil strife and contention. Literature could not avoid the effect of politics: the disturbance of opinion dragged with it into political or religious controversy many who might otherwise have found expression in literature. Even Milton for a dozen years wrote chiefly prose. We cannot, therefore, look for a varied and definite literary development. The greatest work of the century was in prose and the greatest and most influential single monument was the King James version of the Bible (1611). The spirit of the Bible is everywhere to be felt in the great prose of the time, transmuted into varying substance in the eloquence of Jeremy Taylor ('Holy Living,' 1650), the quaint richness of Fuller ('The Holy State,' 1642), the stately roll of Sir Thomas Browne ('Religio Medici,' 1643), the powerful vigor of Milton's prose — written during the Civil War, to answer in his own way the call of the country — and the intimate simplicity of Bunyan. A few other writers have little tincture of the struggle of the time, Overbury's 'Characters' (1614), Burton's 'Anatomy of Melancholy' (1621), Cowley's 'Essays' (1868), Walton's 'Compleat Angler' (1653) works of a widely different nature, but showing the quiet, contemplative side of the century that was so distracted by controversy. The Civil War occurred in the very middle of the century, and makes a definite bar at least with the poetry of the time. Before it was the Elizabethan age; after it the Restoration. The drama and the lyric before and after are different: even the external form of poetry shows a marked change. At the beginning of the century the verse was free and fluent: at the end it had become concise and brilliant. To the blank verse of Shakespeare succeeded the rhymed couplets of Dryden, organic power giving place to elegant skill. In point of time belonging to both, John Milton in reality belongs to neither. More fully than anybody else he is the representative of Puritanism in literature: its zealous rages, its fanaticisms, its blemishes, its love of liberty and of God give life to his prose tracts on church government, on divorce, on freedom of speech, on the acts of the people: its higher dreams and ideals and aspirations, its unattained possibilities of beauty in 'Paradise Lost' (1667), and his later poems.

With the Restoration of Charles II. began a new period in literature, often called the classic, most immediately noticeable in the drama. The influence of France in the direction of strictness of classic art and looseness of moral life, was strong: added to it was a change in stage conditions, which allowed the development of scenic effect. A realistic, if not spectacular, character, was given to the theatre and the Elizabethan plays, with all their poetry, fell out of fashion, save in versions of the day. A new set of dramatists sprang up to fulfill the conditions. Dryden was the chief, equally strong in tragedy and comedy and what he called the heroic drama, after French models. Otway had the greatest tragic genius ('Venice Preserved,' 1682), but could not so well adapt himself to the taste of the age. Congreve, Wycherley, Farquar and many others wrote comedies depicting a brilliant social world, but of such gross immorality that Jeremy Collier (1698) launched an attack on the whole theatre. His words had some effect and the drama became more decent, but as it really seems to have been quite representative of the life of the time (not artificial as Charles Lamb loved to think of it), the succeeding drama lacked vitality, and for a hundred years hardly a play was written which is now remembered. Addison's 'Cato' (1713), Rowe's 'Jane Shore' (1714), Gay's 'Beggar's Opera' (1728), Johnson's 'Irene' (1749), Home's 'Douglas' (1756), are noteworthy for various reasons, but not as constituting a powerful drama. It was in other directions that the 18th century was successful. In 1709 Richard Steele published a small paper every other day which he called the 'Tatler.' It was not precisely a newspaper, but consisted rather of a series of essays on all sorts of subjects, sometimes by Steele, sometimes by Addison, Swift, or a number of others, who lent occasional help to the enterprise. The 'Tatler' was very popular, and was brought to a close only to be continued in the 'Spectator,' in which Addison took the chief part. He took up the idea of Steele and found in it a form of expression exactly suited to his especial powers. His essays were popular in the best sense: they were read with delight by all sorts of people, but they dealt with subjects of intelligent interest. Addison was a student of human nature, an observer of life and character, a genial philosopher and all these elements of his nature were exhibited in the little essays which he wrote for the 'Spectator.' The success called forth followers: Addison and Steele followed their joint productions with separate publications, which were sometimes political as well as literary. Among the many 18th century periodicals should be mentioned the 'World' (1752), by Lord Chesterfield and others; the 'Rambler' (1750), and the 'Idler' (1758), by Samuel Johnson; the 'Bee' (1758), by Goldsmith. The influence of this sort of literature abroad was also very great: it continued even to the beginning of the 19th century, when a number of clever young men of New York, Washington Irving among them, joined in the production of 'Salmagundi' (1807). One distinguishing element in these periodical essays was that of personal character. Some imaginary person was the means by which they were put before the public: the 'Tatler' was edited by Isaac Bickerstaft, the 'Spectator' by a club of the Spectator and others, including the famous Sir Roger de Coverley. This personal element was characteristic of the century, which was extremely sociable and very much interested in human nature. These frequent sketches of character and observations of life and manners were not absolutely new even in England: so-called "Characters" had been not uncommon in the 17th century and were well known in France. This interest in character for itself is paralleled by an interest in life in action observable in the stories of Defoe. Defoe was a man who lived by his pen (one of the first who had not been connected with the theatre or the court), whose great gift so far as literature was concerned was his power of representing life. His famous 'Robinson Crusoe' (1719) attained inordinate popularity, not only for its adventurous incident, but for its power of realistic story-telling. A little more and these things would have been novels. Addison's 'Sir Roger de Coverley' papers are sketches of life and character without a story. 'Robinson Crusoe' and the many other stories of Defoe have too much action, without attention to life and character, in spite of their realism. These elements were combined by Richardson and Fielding: 'Pamela' (1741), 'Clarissa Harlowe' (1748), 'Sir Charles Grandison' (1753), by the former, were immensely read and influenced all Europe; 'Joseph Andrews' (1742), 'Tom Jones' (1749), 'Amelia' (1751), by the latter, are quite as excellent and somewhat more modern in form. Smollett followed with 'Roderick Random' (1748), 'Peregrine Pickle' (1751), and some others, which are a slight variation upon the first of Fielding's. Goldsmith's 'Vicar of Wakefield' (1766), and Miss Burney's 'Evelina' (1778), give us, the one the life of the country, and the other of the town, and we have the English novel of domestic life, a form of literature which for a hundred and fifty years has lost and gained but little in essential character. The essay and the novel were new: such things had been in England before, but never the definite literary understanding necessary to constitute a true literary form. Meanwhile the older forms of literature were not neglected. There had been no such histories in England before Clarendon's 'History of the Great Rebellion' and Burney's 'History of My Own Time.'

These men wrote of what they had seen, later writers learned to take a larger view and handle larger material. Robertson ('Charles V.,' 1769), Hume ('History of England,' 1754-61) and Gibbon ('Decline and Fall of the Roman Empire,' 1776-88), gave example of the combination of scholarly research and literary skill. Oratory also flourished in the exciting Parliamentary struggles which now took the place of court faction. Chatham, Burke, Fox, and many others created a standard and form of eloquence, which yet serves as a model for many speakers and a foundation for more. A special form of oratory becomes important in literature; sermons were vastly read. Barrow, South, Stillingfleet, Tillotson, published their discourses in the last half of the 17th century, and had many successors in the first half of the 18th. The interest in religion was a part of the general intellectual curiosity of the century; philosophy also became a part of literature. Locke's 'Essay on the Human Understanding' (1690) was more widely read than any other book of such a kind. Every one discussed a little philosophy, whether Christian or free-thinker. Berkeley was the former: his 'Principles of Human Knowledge' (1710) has been of importance in the development of metaphysical ideas. Hume was the latter, so much of a skeptic that his 'Essays' (1746) incited Kant, in Germany, to that profound examination of the human reason that has been the foundation of modern philosophy. The 18th century was a century of reason and of prose. Prose was first simple, either graceful as in Addison, nervous in Defoe, or everything in turn in the wonderful prose of Dean Swift, an unapproached master of satire. As the century continued, style became more elaborate, of great dignity and stateliness at its highest points (Gibbon and Burke) and even for ordinary purposes admirably effective as in the best of Johnson. The time was intellectual and loved the things of the intellect; hence its poetry was not such as to satisfy the more emotional periods that came after. It was too obviously didactic or satiric, for one thing. Dryden was the first great master on these directions with the 'Hind and the Panther' (1687), and the 'Religio Laici' (1682). In Pope the classic poetry (as it is called) came to perfection, the 'Essay on Criticism' (1711), and the 'Essay on Man' (1732), the 'Dunciad' (1728) and the 'Rape of the Lock' (1712), have never been equaled in English for their telling brilliancy. The followers of Pope caught something of his manner, but produced nothing great, save Goldsmith, who infused a charm into this as into every other kind of literature. Dr. Johnson wrote two strong poems, but his chief power lay elsewhere. The minor exemplars of the characteristic 18th century poetry are of far less value. Addison as a poet, Garth, Prior in 'Solomon' (1718), Young, the author of 'Night Thoughts' (1742), Blair, 'The Grave' (1743), even Akenside, the author of 'Pleasures of the Imagination' (1744), did not all write the characteristic couplet, but they are all of the classic school and all wrote that intellectual poetry that now seems so strangely unpoetic. In lighter forms of verse there were more successful practitioners, Prior and Gay and Swift, but in didactic and satiric poetry, save in the work of the greatest, the 18th century produced nothing permanent. But during the whole classic century there had existed, in its time had been growing, a feeling for other things than those which the reason could put into brilliant and elegant form. It found expression in various ways, chiefly in love for the mediæval past, before the classic conventions had been, and in a feeling for the present wherever those conventions did not exist, namely, in nature and in the heart of man. The first feeling came to expression in various ways, often imperfect, as when Thomas Wharton wrote 'Runic Odes' (1748), when Gray wrote poems inspired by the Norse, 'The Fatal Sisters,' 'The Descent of Odin' (1761), when Sir Horace Walpole imitated Gothic architecture in his house at Strawberry Hill. In 1760 Macpherson published what purported to be translations of Ossian (also 'Fingal,' 1762; 'Temora,' 1763), and whether they were genuine or not, the fact that they were read shows the interest that was felt in the remote past. In 1767 Chatterton found that he could gain a public for his poetry by pretending that it had been written by a monk of the 15th century. In 1765 Percy published the 'Reliques of Ancient Poetry,' a collection of old ballads, a kind of literature full of the spirit of the past, and absolutely different from the classic poetry of the day. There had been plenty of ballads printed before, even collections of old ballads (Ramsay's 'Tea-Table Miscellany,' 'Evergreen' (1724); and they had inspired a few, but now they became an immense influence. In the other direction, love of nature and sympathy with man. Thomson's 'Seasons' (1726-30) show his fresh and charming view of nature, though his use of blank verse and the Spenserian stanza was more in keeping with earlier times. Gray produced very little poetry, but his best, the famous 'Elegy' (1751) has none of the brilliancy and intellectuality which marked the century, and it is noteworthy that in stanza 15, where he originally wrote the classic names of Cato, Tully, Cæsar, he afterward put the national names of Hampden, Milton, Cromwell. Burns was far too much of a man to be bound or curbed by fashions, unless they had been far more congenial than those of the 18th century. He took inspiration from the ballads and songs of his own country and produced poetry which touched the heart at once. Cowper, though by no means like him, nor apparently of the character of a reformer at all, wrote with a sincere directness that belonged to an earlier or a later time. The turn of the century shows the characteristic works of the Romantic movement: 'Tintern Abbey' (1798) and 'Michael' (1800), by Wordsworth, may represent the poetry inspired by love of nature and sympathy with man. Coleridge's 'Rime of the Ancient Mariner' (1798), and Scott's 'Lay of the Last Minstrel' (1805, preceded by 'Minstrelsy of the Scottish Border,' 1802) stands for the delight in ballads and mediævalism. With these fine poems and others only less so, it is plain that a new form of art has appeared different *in toto* from the classic conventions of the 18th century. The first great excitement of romance was for strange adventure and the glowing life of the Middle Ages. Wordsworth was for the time unread, while the poetry of Scott delighted all. Scott, however, was eclipsed in the popular mind by Byron, who really was personally the very thing that Scott and the public admired. They longed to hear of men of lofty spirit and recklessness and devotion. Byron was such a man; in 'Childe Harold' (1812) he took England out of itself. In the 'Gaiour,' 'Bride of Abydos,' 'Corsair,' 'Lara,' 'Parasina' (1813-15), he presented figures full of the romantic spirit. As the century continued, however, that spirit expressed itself in all sorts of different ways. Wordsworth presents the common delight in nature, Shelley, noble ideas for the regeneration of mankind. Keats, the power of beauty. Succeeding poets go in much the same directions. Tennyson is the most representative poet of the century in presenting to us in forms of great poetic beauty, all the phases of the thought of the time, religious, scientific, patriotic, literary. Browning gives us a vigorous optimistic conception of life and work, presented in a wonderful series of dramatic figures. Morris, Rossetti, Swinburne (sometimes called preraphaelites) may be said to follow Keats in their love of beauty, which they seek not only in mediævalism, but throughout all history sacred and profane. Matthew Arnold's poetry has classic qualities of style and great eiegaic charm of thought, but he rightly saw that his true field lay elsewhere. The drama has been weak for the whole century, although all the greater poets essayed the form. Only Browning and Tennyson had even temporary success on the stage, while the work of the professional play-writers have without exception failed of a place in literature. By 1800 the novel had become a definite form of literature. In the early years of the century Miss Austen, Miss Edgeworth, Miss Ferrier produced pictures of life in England, Ireland and Scotland, respectively, the first of surpassing excellence. A great change was effected by Scott in the Waverley novels (1814-31). It has been pointed out that the lasting power of these novels depends on their full and vital knowledge of Scotch life and character. Scott, at the beginning, had some idea of doing for Scottish life what Miss Austen had done for English. But the real immediate effect of the Waverley novels was to give an enormous impulse to the romance of adventure and scenery and costume, a romance which found its best expression in the historical novel. The Waverley novels are great historical novels, though, of course, some have little history in them, and they gave a conception and an inspiration which was not wasted. In 1825 appeared the first works of importance of G. P. R. James and of Harrison Ainsworth, who for a quarter of a century achieved a very considerable popularity, though they added but little to the possibilities of historical fiction. More powerful than either was Bulwer, whose first work appeared in 1827, and who for forty years produced not only historical novels, but novels of every kind, works of great talent, though the judgment of time refuses them genius. At much the same time two other writers somewhat extended the field of the novel: Marryat, by sea-stories, which remind one of Smollett; Charles Lever, by stories of the army as well as of Irish life. Brilliant historical novels have appeared through the century: Thackeray's 'Henry Esmond' (1852), and 'The Virginians' (1857); Kingsley's 'Westward Ho' (1855), Dickens's 'A Tale of Two Cities' (1859), Charles Reade's 'The Cloister and the Hearth' (1861), George Eliot's 'Romola' (1862), Blackmore's 'Lorna Doone' (1869), Shorthouse's 'John Inglesant (1880), Pater's 'Marius the Epicurean' (1885), constitute a series of remarkable value. But the great successes of fiction in the middle of the century were made in the long-familiar forms. Charles Dickens had many minor characteristics, and so had Thackeray, but their novels, as well as those of George Eliot, are novels of every-day life. In the main these three are realists, striving chiefly to depict the life that they knew and saw about them. So chiefly were those who came after them. The Brontés, George Meredith, Charles Reade, Anthony Trollope, William Black, Thomas Hardy, George Gissing, these are realists also, though in only the last two cases of the consistent type developed by their contemporaries in France. Some of them sought in every-day surroundings the romance of character like the Brontés, some could perceive the rich spirit of comedy like Meredith. But none felt the need more than once or twice of straying from the familiar life of England. Toward the end of the century the craving for romance began again: it had never been entirely quieted, but it did not come to full expression till Stevenson and Kipling. Both sought the romance of life and character and of the soul, but both were masters also of adventure and incident and striking circumstance and flowing background. Anthony Hope, Stanley Weyman, Conan Doyle, Maurice Hewlett, have in general followed, and in some cases surpassed them. A third development of the century has been in the path of criticism, which at first found expression chiefly in the periodical. The magazine has been one of the most characteristic elements of 19th century literature. There were magazines in the 18th century — the 'Monthly Review,' the 'Critical Review,' the 'Gentleman's Magazine' — but the chief periodical was the Addisonian essay. The 'Edinburgh Review' (1802) and the 'Quarterly Review' (1809) were the beginning of a new movement. 'Blackwood's Magazine' (1817), the 'London Magazine' (1820) and 'Fraser's Magazine' (1830), together with many weeklies and dailies, were the beginning of a flood of literature that is now the form most familiar to us. The influence was at first chiefly critical. Jeffrey, the first editor of the 'Edinburgh,' with Gifford of the 'Quarterly,' set the style of a criticism, which though often unfairly slashing and ridiculously high and mighty in tone, had merit often in expressing sincere and definite opinions in literature and politics. A sort of gaiety and even charm was given by Wilson, who wrote under the name of Christopher North, by Sidney Smith, and Lockhart. But the most important developments came in the field of the personal essay. The 'Essays of Elia' (1820) by Charles Lamb, go beyond the Addisonian essay in their unfettered expression of a charming personality. 'The English Opium Eater' (1821) of Thomas De Quincey, is still farther away from the 18th century in form and spirit, and so is the 'Table Talk' (1824) of Hazlitt. All these are sincere personal utterance, and in their sincerity and personality lies their strength. In the main we may call the work of these men critical, for they were all absorbed in letters, and their view of life was essentially a criticism of literature. Something more in the way of established form were the famous Essays (beginning 1825) of Macaulay. The most remarkable works of their time in the power of focusing wide reading and immense knowledge into forms of extreme brilliancy. A striking contrast is offered by Carlyle, who began by essays of the accustomed character, though not ordinary in style, but after some years produced 'Sartor Resartus' (1833), expressive of his own vigorous personality and thinking, more extraordinary in form than any of his later work, but not more original or powerful. Carlyle had by no means the immediate fame of Macaulay, but his influence on the thought of his time has been vastly greater. Both were historians as well as critics, and by their interest in life and sympathy with man they brought in a new and fascinatingly interesting kind of historical writing, which the later influence of Darwinism and of science in general, has done much to deaden. Hallam before them should also be mentioned, and Green after them. John Ruskin began his career as critic with what seemed the impossible task of dethroning false masters of painting, and establishing an ethical foundation for art. About 1850, having succeeded in his earlier task, he began a struggle against a much wider range of evil, which was not so fortunate. Matthew Arnold also understood the range of the critic as extending beyond the field of art: his views on politics and religion were an influence in the history of thought, but naturally will not last as long as his conceptions on literature. Walter Pater took even a wider view of art, being at home with painting, architecture, sculpture, as well as with literature. He represents the so-called "æsthetic" position which developed from preraphaelitism. In philosophy and science the century has been pre-eminent, and many great books have been produced. The last field hardly belongs to literature, although Darwin, Huxley, and Tyndall were masters of style and could make the results of scientific work absorbingly interesting. More might be said of philosophy and theology, though here little has been produced that will last as literature, except perhaps John Stuart Mill's 'Logic' (1843), Cardinal Newman's 'Apologia pro Vita Sua' (1864), and parts of Spencer's 'Synthetic Philosophy' (1860-1900), all of which stand as representative of important movements in the history of thought.

There are many histories of English literature. That of Garnett and Gosse is an excellent general account, richly illustrated by extracts and reproductions of manuscripts and prints. The three volumes on different periods by Saintsbury and Gosse cover the last four centuries in a convenient form. The work of Taine (translated by Van Laun) expresses his views of the development of literature from national life. That of Ten Brink (translated by Keneday) is unfinished, but covers the ground where German scholarship is strongest, namely, Anglo-Saxon and Middle English. Brandl, in Paul's 'Grundriss der germ. Philologie,' gives a very full and convenient summary. Morley's 'English Writers' is a very full account in ten volumes, but has not got beyond Shakespeare. The 'English Men of Letters' series provides lives of the greatest authors. Ward's 'English Poets,' and Craik's 'English Prose,' are valuable, giving a summary of facts, a criticism by a writer of note, and a number of extracts in case of all distinguished poets and prose writers.

EDWARD E. HALE, JR.,
Professor of English, Union College, Schenectady, N. Y.

English Literature, Middle Period. The term Middle English may conveniently be taken to include the period 1100-1500. For more than a century after the Conquest, however, the majority of works produced and read in England were written either in French or Latin. Literature in the vernacular, which had sunk to a low level by the beginning of the eleventh century, did not revive materially until the reign of John. The Anglo-Saxon Chronicle, continued to the year 1154, and a few religious works, chiefly of linguistic interest, almost exhaust production in English during this era of transition. During the thirteenth century English began to compete with the other tongues for supremacy, and by the time of Chaucer its victory was assured, although French and Latin continued to be widely used. At first, the progress of the vernacular was greatly hindered by dialectical differences in various parts of the country. The West-Saxon and Kentish, the Mercian, and the Northumbrian of the earlier period had developed respectively into the Southern, Midland, and Northern, with some changes of boundary. Of these, East Midland was most important, as the dialect of London and Chaucer, and the parent of Modern English. The language as a whole shows very marked differences from Anglo-Saxon, not only in the addition of many foreign words, chiefly French and Scandinavian, but in changes in the vowels and diphthongs, in the disappearance of inflectional endings, and in a freer use of particles and connectives. The dialectical peculiarities gradually became less marked, until at the end of the period there was practically only one literary dialect, with the exception of Scottish.

The influence of Anglo-French and Anglo-Latin upon Middle English was exceedingly important. The Normans took great interest in historical writing after their settlement in England, as the Latin chronicles of such men as Ordericus Vitalis, Henry of Huntingdon, and William of Newburgh attest. About 1136 Geoffrey of Monmouth produced his fictitious 'Historia Regum Britanniæ,' a book condemned by serious historians, but of great significance for mediæval romance. It was later reworked in French rhymed versions by Gaimar and Wace. The Normans were fond of romantic stories, and even retold the deeds of various native English heroes in their own tongue. More serious historical work was done in French verse by such men as Garnier de Pont St. Maxence or Jordan Fantosme. Churchmen like Lanfranc and John of Salisbury wrote on theological matters, and there was early much activity in the new English Universities. Latin writing of a lighter sort is represented by the 'De Nugis Curialium' of Walter Map, or the 'Speculum Stultorum' of Nigellus Wireker. The Normans were a people of practical mind, and most of their literature consisted of utilitarian or devotional prose. Scientific facts, or supposed facts, interested them greatly. They were clever tellers of tales, both of the fabliau type and those pointing a moral. Especially noteworthy is the work of the poetess Marie de France (1175-

1185), who wrote a charming collection of *Lais*, and a book of fables, the 'Ysopet.' The rise of the drama on English soil was due almost wholly to the influence of the French.

Earlier Middle English literature is better studied by types than by authors. Originality, as a general thing, counted for little in mediæval days, and works in the vernacular during the 13th century were based almost without exception upon French and Latin models. The narrative literature is of far greater interest than the religious and didactic writing. The French metrical romances, artistic poems dealing with love and war, and intended for the higher classes, were rapidly made accessible to the English after the middle of the 13th century. The cycle of King Arthur and his knights was the most important and popular. A smaller and less favored division dealt with "the matter of France."—the deeds of Charlemagne and his warriors. A third group is based on native English and Germanic themes—King Horn, Havelock, Bevis of Hampton, Guy of Warwick, etc. Stories of Troy and Thebes form a fourth class. The Troy-story deserves attention because of versions of the Troilus-Cressida theme by Chaucer, Henryson, Lydgate, and Shakspere. Romances of Eastern origin, with a few others not readily classifiable, complete the list. By the time of Chaucer, the metrical romances were showing signs of degeneration, and in the 15th century they died a lingering death. In strong contrast to these are the fabliaux, short witty rhymed tales, intended for the lower classes, usually of a satiric character, and frankly indecent. They were never as popular in England as in France, although stories of this type form the largest genre-division of the 'Canterbury Tales.' Pious tales, generally representing supernatural occurrences in every-day life, and beast stories, like the 'Fox and the Wolf' (13th century), were popular. Noteworthy, too, are the collections of stories, often, as in the case of the 'Gesta Romanorum,' used by preachers as *exempla* upon which to base homilies. Many romantic narratives reappeared in altered form in the ballads. These "stories in song" differed widely from the romances, being short, stanzaic, allusive pieces of unknown authorship, perpetuated among the people by oral tradition, and dealing with a great variety of material. The popular lyric—quite a different thing—is represented by such pieces as 'Sumer is icumen in,' or 'Blow, Northern Wind,' which strike a more truly English note than the art-lyrics of the period. Secular love-poetry was often applied to religious ends, as in the 'Love-Rune' of the Franciscan monk, Thomas de Hales. In the 14th century French lyrics were extensively imitated, as the work of Chaucer and Gower shows. As for metrical chronicles, three deserve especial mention. Most important is the 'Brut' of Layamon (ca. 1205), so called because it traces British history from Brutus. Although dependent upon earlier French and Latin work, it shows imaginative power and patriotic feeling. The same love of England appears in the chronicle of Robert of Gloucester (1298), which may have been written by more than one man, and in the historical work of Robert Mannyng of Brunne in the 14th century.

The devotional and didactic literature is somewhat difficult to classify, since the various types were not always clearly differentiated, and borrowed much from secular writing. A favorite form of conveying wisdom was the proverb poetry. An early collection of this sort was attributed to King Alfred, and another was put into the mouth of a personage called "Hending." A similar purpose was served by the "debates," the most noteworthy of which is the 'Debate of the Body and Soul' (12th century), in which each speaker accuses the other of being responsible for the death of the dead man. The 'Owl and Nightingale' (ca. 1220) is the most important secular debate in English. There was much work on scientific subjects, and this was often made to point a moral, as in the 'Bestiary' of the early 13th century, which appends a "significatio" to each description. A vast number of homilies and devotional treatises were written. The 'Poema Morale,' "a penitential sermon in verse," dates from 1170. The 'Ancren Riwle,' or Rule for Nuns, is an early prose monument of some importance. More celebrated is the 'Ormulum' (ca. 1200), a set of pedestrian metrical homilies valuable to the philologist on account of a peculiar system of spelling. In the 14th century, Dan Michel of Kent, the author of the 'Ayenbite of Inwit,' William of Shoreham, who wrote stiff didactic poems, Robert Mannyng of Brunne, who versified a French manual and gave it the title 'Handlyng Sinne,' and Richard Rolle of Hampole, are all noteworthy. Richard Rolle, the mystic, hermit, and preacher, was more important as a personality than an author, yet his works, of which the 'Prick of Conscience' is the best known, were esteemed in their day. Chief among Bible-paraphrases are an early version of Genesis and Exodus (ca. 1250), in the Midland dialect, and the 'Cursor Mundi,' written in the north. Legends and lives of the saints were much in demand, and huge legend collections were made for homiletic work. The Tales of the Prioress and Second Nun in Chaucer illustrate this genre.

The most prominent figure in Middle English literature is Geoffrey Chaucer (1340-1400). A Londoner by birth, he was brought up in the atmosphere of the court, took part in the French wars, was often employed upon diplomatic missions, and held various public offices. His literary work falls naturally into three periods. The first, extending to about 1372-3, when he first visited Italy, reflects the influence of French poetry. Besides a number of shorter lyrical pieces, most of which are not extant, the period includes a translation of a part of the 'Romance of the Rose,' and 'The Book of the Duchess,' a lament for the death of the wife of his patron John of Gaunt. The second period, which closes about 1385, reveals him imitating Italian models, particularly the works of Boccaccio. Here belong 'Troilus and Cressida,' 'Anelida and Arcite,' 'The Hous of Fame,' 'The Parliament of Foules,' and some stories later utilized in the 'Canterbury Tales.' This period shows a great advance in versatility and poetic power. The so-called English period, in which he attained the summit of his powers, has been held to include the 'Legend of Good Women,' but recent research puts much of it earlier, and makes plain the strong influence of French. The chief work of this period, and his masterpiece, is the 'Canterbury Tales.' The stories were borrowed from various sources; the plan of the whole resembles that of the 'Decameron,' but there is no evidence that Chaucer was acquainted with it. Besides the two prose Tales, Chaucer translated Boethius, and wrote a treatise on the Astrolabe. The chronology of his writings has not yet been exactly determined.

Four important alliterative poems of the latter half of the 14th century, written in the West Midland dialect, may be referred to one author, whose name has not been preserved: 'Sir Gawain and the Grene Knight,' 'The Pearl,' 'Cleanness,' and 'Patience.' The first of these is generally considered the finest of the metrical romances, because of its elevation of tone, descriptive power, and narrative skill. It is written in a highly artificial style of verse. 'The Pearl' describes the appearance of a beautiful maiden in Heaven, seen in a dream. It is probably to be interpreted allegorically, although the poem has often been held to reflect the grief of a real bereavement. The other two poems, which are of minor value, exalt the virtues indicated in their titles. Alliterative verse, without end-rhyme, was employed by William Langland, whose bitter satire contrasts with the genial irony of Chaucer. 'The Vision of Piers the Plowman' attacks the evils of the day by means of allegorical figures seen in a series of dreams. A continuation of the same material appears in the pieces called 'Do Wel,' 'Do Bet,' and 'Do Best.' The allegory is sometimes realistic and sometimes mystic. The 'Vision' appeared in three different versions in the latter part of the 14th century. It has been doubted that this is all the work of one man, and too much weight has been attached to supposed autobiographical evidence in it. 'Richard the Redeless' is generally assigned to Langland.

The fame of John Gower (died 1408) rests, apart from a series of French *ballades*, and minor pieces, upon three works, the 'Speculum Meditantis,' a moral allegory in French verse, the 'Vox Clamantis' in Latin, dealing with the social unrest of his day, and the 'Confessio Amantis' in English, his best-known poem. The 'Confessio' consists of a series of tales, strung on a thread of story. The priest of Venus is sent to "confess" the lover, and gives him instruction by means of tales illustrating the vices and virtues, with special applications to matters of love. Many of these tales are well and simply told, but the artificial and highly finished octosyllabic couplet soon becomes monotonous. The poem is too long (nearly 34000 lines), and is far inferior to the work of Chaucer. An enormously prolific poet, too, was John Lydgate. His long poems, like 'The Troy-Book,' or 'The Falls of Princes,' are tedious versifying; his minor poems and *Fables* show him at his best. As a disciple of Chaucer he stands with Thomas Occleve or Hoccleve, a more interesting personality, but less productive and accomplished than Lydgate. Occleve's chief work is 'The Gouvernail of Princes.'

The prose work of John Wycklif was primarily utilitarian. He was greater as a personality than as a writer, but his translation of the Bible (ca. 1380) did much to fix the form of the language, and his simple and direct sermons appealed strongly to the lower classes. He was assisted in translating the Old Testament by Nicholas of Hereford, and the whole was later revised by John Purvey. An undue importance has sometimes been attached to the fictitious 'Travels' supposed to have been made by a Sir John Mandeville in the 14th century. The book was originally written in French, but the facts of its authorship are not yet fully known. Though purporting to be authentic, it is full of grotesque descriptions of the East, mostly borrowed from mediæval travel-books.

The 15th century was a singularly barren era. England was almost devoid of poetry of distinction; the example of Chaucer inspired little in the south, and the Wars of the Roses had a most unfavorable effect upon literary production in general. Some advance was made in prose writing, however, through the interest taken in historical, legal, controversial, and religious subjects. Reginald Pecock, the great opponent of the doctrines which had been advocated by Wycklif, is remembered for his 'Repressor of Overmuch Blaming of the Clergy.' Sir John Fortescue, the author of 'The Gouvernance of England,' and the chroniclers Capgrave and Fabyan also deserve mention. Perhaps the most distinguished work of the century was Sir Thomas Malory's 'Morte Darthur.' This collection of romantic tales dealing with King Arthur and his knights, told in melodious prose with great skill and charm, was finished about 1470, and printed fifteen years later by Caxton. Of the life of Malory little is known. Although he invented little, he was no mere compiler, but a great literary artist. The introduction of printing and the publications of Caxton mark a new era in English letters. Much of the material which Caxton printed he translated from other languages himself. His activity exerted a strong influence in the development of English prose.

A compensation for the dearth in English proper in the 15th century appears in the emergence of Scottish literature. The first noteworthy work in this dialect, with the exception of certain legends and romances, is the 'Bruce' of John Barbour, whose life falls within almost the same dates as that of Chaucer. The poem partakes of the nature both of a rhymed chronicle and a romance, and though lacking in finish, is full of vigor, and animated by patriotic spirit. It celebrates the deeds of Robert Bruce, with occasional lapses from historical accuracy. Andrew of Wyntoun's 'Original Chronicle'—so called because he began from the very beginning—is an exceedingly monotonous piece of versifying. The exploits of William Wallace were celebrated by Henry the Minstrel, or Blind Harry, as he is often called, in a poem which takes great liberties with history. Blind Harry died about 1492. A pronounced imitator of Chaucer, and not an unworthy one, was King James I. of Scotland, who celebrated his love for Lady Jane Beaufort in 'The King's Quair' (1423). In structure, language, and general literary treatment it is highly artificial, but full of grace and poetic feeling. It derives additional interest from the romantic career and early death of its author. In variety and excellence of work, Robert Henryson, who flourished in the latter part of the 15th century, holds an important place. He wrote the earliest extant English pastoral, 'Robene and Makyne,' and a notable collection of 'Fables.' The influence of Chaucer is seen in 'The Testament of Cressid,' which describes Cressida's unhappy death with great dramatic power. In minor poems he was often felicitous. An elaborate, though tedious and awkward bird-fable is the 'Howlat' or 'Owlet' of Holland. The greatest poet of the period was William Dunbar (1460?-1520?), who led a wandering life in his youth, was later attached to the court of James IV. of Scotland, and entered holy orders. Most of his poems are short, and a large number of them are satirical. More ambitious are 'The Thistle and the Rose,' which commemorates the marriage of the king, and 'The Golden Targe,' an elaborate allegory. 'The Dance of the Seven Deadly Sins,' 'The Flyting with Kennedy,' a brother-poet, 'The Two Married Women and the Widow,' and 'Tidings from the Session' are all representative pieces. 'The Two Friars of Berwick,' a piece of vigorous Chaucerian narrative, is ascribed to him. 'The Lament for the Makers' strikes the elegiac note, but Dunbar was, on the whole, lacking in pathos and tenderness. He was a poet of great variety and originality, using both the "aureate style" then in vogue, and the rude dialect of the people with equal skill. Gawin Douglas, Bishop of Dunkeld (1475-1522) wrote rather stiff allegorical poems, 'The Palace of Honor,' and 'King Heart.' His most important work is his translation of Vergil. Douglas was the most learned of the Scottish poets, and his work was designed to appeal chiefly to the upper classes. Much of the work of Dunbar and Douglas falls outside the formal boundary of this literary period, 1500, yet in the general character of their poetry, and especially in their imitation of mediæval models they are properly to be considered with the earlier men. The same is hardly true of the work of Sir David Lyndsay of the Mount (1490-1545), who completes this group of Scottish poets. The reformatory tone and national appeal in his writings place them in the era following.

In English literature proper a similar distinction is to be made. Alexander Barclay's translation of the 'Narrenschiff' of Sebastian Brandt, which he called 'The Ship of Fools,' and 'The Pastime of Pleasure' of Stephen Hawes, a "belated Chaucerian," both produced in the first decade of the 16th century, belong far more to the age that had passed than does the poetry of Skelton. Although some of Skelton's early work suggests imitation of the older poetry, his most characteristic pieces do not fall within the bounds of Middle English. Neither Hawes nor Barclay were even second-rate poets; their prominence is chiefly due to the fact that they lived in a time when little poetry was written.

The Miracle Plays flourished in England from the early part of this period until the end of the 16th century. The Morality Play, a less important genre, arose in the second quarter of the 15th century, and, with the Interlude, for a time rivalled the popularity of the Miracles. For a discussion of the rise of the drama in the Middle English Period, see MIRACLE PLAYS.

Bibliography.—The most recent and detailed discussion of the earlier Middle English period is by W. H. Schofield, 'English Literature from the Norman Conquest to Chaucer,' which contains bibliography and chronological tables; for individual authors consult the 'Dictionary of National Biography'; for bibliography, G. Koerting, 'Grundriss der gesch. der engl. Litteratur'; for literary history in general, B. ten Brink, 'Gesch. der engl. Litteratur' (English tr. in 3 vols.); A. Brandl, in Paul's 'Grundriss der germ. Philologie'; Jusserand, 'Literary History of the English People' (2 vols.); H. Morley, 'English Writers' (vols. 3-7); Saintsbury, 'A Short History of English Literature'; R. Wuelker, 'Gesch. der engl. Litteratur.' For the French literature of the period, cf. G. Paris, 'La litt. franç. au moyen âge,' 'Mediæval French Literature,' in Temple Primer Series. For the Scottish poets, T. F. Henderson, 'Scottish Vernacular Literature, A History'; D. Irving, 'History of Scottish Poetry,' ed. J. Carlyle.

WILLIAM WITHERLE LAWRENCE,
Instructor in English, Columbia University.

English Modern Political Development. The signing of the Magna Charta in 1215 by King John had sown the seed for future constitutional liberty. This came in the shape of the great Protestation in 1621, in which Parliament delegated unto itself the right to discuss state affairs; the Petition of Rights in 1628, prohibiting taxation without the consent of Parliament; the famous Bill of Rights, passed by the Convention Parliament of 1689; the Toleration Act of 1691, allowing Dissenters the freedom of public worship; and the establishing of triennial parliaments and the freedom of the press. At the close of the 18th century, England was an impoverished, benighted, and backward country. A reduced population of 10,000,000 was oppressed with an enormous debt, which it seemed to be hopeless to attempt to pay. America had been lost through a stupid attempt at subjugation, and Ireland was ripe at any time for revolt. Wealth was so unequally distributed that, while the artificial rise in wheat and land enriched the small class which controlled legislation, the bulk of the population was pauperized. The general level of education was so low that the attempt to introduce machinery into a country destined in large measure to live by means of it, led to riots. The press was shackled, the bench far from free, the civil service the football of patronage, and crime was steadily increasing, through the operation of a criminal code, so barbarously severe as to be worse than useless. Yet out of these unpromising beginnings has emerged the England of our day—the England of a great literary, scientific, commercial, and political people, a dominion on which the sun never sets, the country which divides with us the repute of having the greatest resources and greatest enlightenment of modern times, the home of individual freedom and honest administration.

The most marked trait of the management of their affairs by the English in modern times (and much of the dislike of them abroad has been caused by it) has been its commonplace rationality. The age which dawned upon the world with the American and French Revolutions was to Bentham and to Burke no less than to Paine, the Age of Reason, and reason in English minds has never been the abstraction which flourished under the same name in France and wherever French philosophy gained a footing. Pure democracies, as the pages of Athenian, of French, and of American history show, have a fondness for abstract principles of government, which is apparently connected with another recognized tendency of democracies — to be carried away by phrases. Both in France and America, the rise of democracy 100 years ago was marked by attempts to found the system on some broad theory, such as the rights of man, equality, or the social contract theory. All the great Americans who gave life and form to the movement ending in the complete democratization of our institutions, from Jefferson and Franklin to Lincoln, as well as the French constitution makers from 1789 to 1848, were impelled by the idea that they had discovered a new principle of government, which could solve the perplexities of its problem, bring to an end the oppression of man by man, and change the world from a vale of tears into an abode of happiness. To the more phlegmatic English, the Age of Reason was to be somewhat different and saner. Burke and Bentham and Adam Smith in their different fields were great rationalists; but they did not dream of making the world over. Bentham appealed to the principles of utility, the greatest good to the greatest number, a purely practical standard; the political philosophy of Burke, which first led him to sympathize with the American, and afterward to detest the French Revolution, was based on the simple truth, hitherto almost unrecognized and still only slowly establishing itself in the human mind, that the welfare and decay of states is governed by laws analogous to, and at many points identical with, those which determine the prosperity and failure in life of individuals.

Comte insists that all human knowledge passes through three stages, the religious, the metaphysical, and the positive or rational. There is no field in which the Comtean law seems to work more clearly than that of government. For ages mankind appeals to revelation and divine right; this idea being expelled, we are taught that "equality" or "natural right" is the true substitute. The final stage is reached when it is discovered that the only real appeal is to reason. All the great publicists of the 18th century guessed the secret. Their followers in England and America applied it.

A real Age of Reason can hardly prove an era of violent change. In England, since the Reform Bill of 1832, while institutions have been liberalized, nothing has been destroyed. The terrors of the law have been mitigated; its firmness has not been impaired. The press has been made free without being allowed to become licentious. Liberty of worship has been established, and in Ireland the connection between Church and state has been dissolved, but the Church has not been despoiled. Slavery has been abolished, but the slave owners compensated. The control of the crown and the great landlords over elections has been shaken off, and the House of Commons made strictly representative; but the freedom of the representative to act in accordance with his own convictions has not been tampered with. Trade has been made free, and this with absolute indifference to "reciprocity"; English ports are open to the trade of the whole world, no matter how much any other nation closes its own — the crowning triumph of Liberal ideas as to commerce. The old colonial system in all the large English speaking colonies has been abandoned, and a federal system of nearly independent states established in Canada and Australia. A blow at privilege in the army has been struck by the abolition of the purchase of commissions. The immense national debt left by the wars with France has been greatly reduced; and a nearly consistent policy of peace with foreign nations pursued. The land question in Ireland, the constant seed of trouble for centuries, has been disposed of, and all these things have been accomplished without resorting to violent or extreme measures or destroying any established institutions. These are the reforms dreamed of in the 18th century, some of them first introduced in England.

But the form and theory of the English Constitution are still wonderfully unchanged. It is the fashion to speak of the transformation of English society and government and law and manners which the last 100 years has introduced, as the "democratization" of English institutions; but the word would rather be rationalization. The state, the Church, the aristocracy, and the crown still exist as potent factors in the Constitution; privilege plays a great part in the law, and birth and family count socially for more than they are worth. The House of Commons has been democratized, so far as a wide suffrage can of itself effect this result, and the civil service has been thrown open, and the abuses which Burke said he loved to hear "clamored against," overthrown; but the actual control of the government is still to a great degree in the hands of the wealthy and titled classes.

The most important constitutional change of our day in the democratic direction was, curiously enough, unconsciously accomplished. When Bagehot published his account of the English Constitution in the sixties, few people in England were aware of how supreme the House of Commons had become, or how its supremacy had been obtained. Bagehot showed how the ministry (which actually carries on the government) had ceased to be the agent of the Crown, and grown to be a sort of committee representing the party having for the time being the majority of the Lower House. The Crown could no longer refuse to call Mr. Gladstone or Mr. Disraeli, as the case might be, to form a ministry; and as it was admitted that the House of Lords could no longer refuse to pass a bill persistently demanded by the people's representatives, the first inference seemed to be that the English government had become a parliamentary democracy with but a single chamber; without even the checks and balances of the American Constitution, or its division of powers and judicial control over the legislature. Sir Henry Maine was so much impressed with this idea that he wrote a book to prove that England had become a "pure" democracy. But even here the democratization of institutions was not nearly so complete as it appeared on the surface. Through all the changes of the century, the crown has remained in control of foreign affairs, at the head of the Church and the aristocracy; society and wealth have been its allies and the great equalizing influence of mere numbers which has played such a potent part in British politics, has obtained but a slight control in England.

Of course, it would be absurd to attribute the totality of progress in any country to a single cause. The advances made by science and invention count for much; and every country has had its share in the common progress which made the 19th century mark a turning point in the world's history. But when we reflect that in every country the great advance was preceded by a struggle between the advocates of freedom and the old order, in which the former were triumphant, and through which they obtained control and shaped the policy of government, the inference is inevitable that free institutions have enormously contributed to the advance. Those in any country who deny that its welfare is bound up with the rationalization of human institutions have no evidence to appeal to. The pages of their own past are black with the proof of human happiness, comfort, content, and peace, even in as moderate degree as they have yet been realized not only did not exist, but (as long as the final court of appeal in Church and state was authority and privilege) were regarded generally as a rather silly dream; they have advanced in the last 100 years *pari passu* with those rationalizing changes which in some countries have taken the form of democracy, and in England of deliberate and continuous institutional reform through the growth of popular power.

A generation had grown up which had enjoyed all the benefits of rational, free government, and yet had a comfortable state Church, a satisfactory aristocracy and magistracy, an army and navy officered by gentlemen, an excellent press, a well administered system of justice, a trained and honest civil service, and a full purse. The abuses which the old Liberalism had been called to destroy had been destroyed. Was it worth while to go on, after all this, to introduce democracy for the sake of making things systematic? America and France had both started pure democracies but England had secured the benefits of solid, good government without doing anything of the kind. It was not Imperialism which broke the Liberal party in two under Gladstone, and has kept it divided; it was the aversion for sweeping theoretic changes in the national habits which has always been characteristic of the English people.

The remoter causes which have led to the present reaction against Liberal ideas, the tide of which has been swelling for 25 years, are no doubt numerous and diverse. Following on a régime of reason, it seems in some respects like a reaction against reason itself; as if the new generation had got tired, as an individual might, of being reasonable, and were resolved to try something else. It has its economists, who teach that every country, if not every town, city and village, has its own political economy; its historians, who think that what really improves the human race is violence and war. Its poet sings the praises at once of law, order, discipline, violence, blackguardism, and brutality. The writers who heralded it, like Froude, Carlyle, and Ruskin, deified force or imagination, laughed at reason, and delighted in ridiculing the absurdities of the economists under the guidance of whose teachings English commerce and the English language have spread over the earth. Its publicists assure us that the secret of the permanent grandeur of free nations, is plenty of distant colonies, and a huge army and navy and its priests make a laughing stock of themselves and the religion they profess, by preaching the sword as the true means of spreading the gospel of peace. The reaction teaches that protection and government bounty, that is, taxation, is the true source of wealth, and that privilege is the buttress of common right. It is imperialistic and military — that is, it appeals to the passion for foreign dominion, to greed and pride, while it pretends to be democratic because it appeals to an extended electorate, though its success paralyzes every democratic impulse. But there are many causes tending to prevent even a reaction in England from going to extremes — among others the publicity in the glare of which most public events are now transacted. An instance of this is the publicity being brought to bear in all its phases on one of the most recent developments against the "open door," — Mr. Chamberlain's crusade in 1903 for "protection."

It may be observed that foreign relations — the stronghold of this and every other reaction — have never been rationalized in England, nor completely in any country. The foreign office is the only secret branch of government left; and through it the executive retains, no matter what the nominal constitutional checks, the privilege of plunging any country into war without notice, and of explaining the event in any way it chooses. At the same time, none of the great powers, even of those who have most to gain by it, is ready to diminish the risk of war by agreeing in advance to arbitrate its differences. This makes it almost as easy today as it was 100 years ago for a government to get up a war for one reason and inflame the public into support of it by other and totally different reasons. Experience shows that no government function that is secret can long be honestly and properly administered. This is why the doors not only of courts of justice, but of the legislature and other public bodies, have been thrown open. Perhaps the time will some day come when the same principle will be seen to apply to the transactions of states between themselves. The principle of arbitration would of itself entail publicity as to all international differences.

On the whole, modern political development in England tends to establish, among others, the following conclusions:

(1) That there is no intimate connection between the mere form of a government and national prosperity. In England we find, at the height of its prosperity, monarchy, artistocracy, and democracy existing side by side. In South America we find democratic forms producing very little prosperity.

(2) That the conservative opinion so long maintained that the popularization of institutions necessarily produces disaster, tumult, and anarchy is a mistake, the extraordinary prosperity of England having advanced *pari passu* with the popularization of her institutions.

(3) That one of the secrets of prosperity is the emancipation of trade and industry, so far as possible, from all forms of control. The "open door" of which we now hear so much is only an illustration of this principle.

(4) That public business cannot be managed behind closed doors without becoming the private business of those who carry it on.

(5) That wherever government is popular and representative, success in the management of public affairs is dependent wholly on conscious, determined effort at improvement, ex-

actly as is the case with individual effort at self-improvement in private life.

(6) That the way to secure competency, fitness, and honesty in the public service is to follow the methods pursued in private life.

(7) That the worst way to settle any public question is violence, that is, war. During the period of England's great prosperity, 1850–80, she engaged in no important foreign war except that of the Crimea, which was inconclusive and useless.

The enthusiasts of the 18th century were laughed at for putting these ideas into people's heads. The reactionaries of to-day are trying to disprove them. We have in the contemporary history of England a monumental indication that the task will be impossible. See BOER WAR; CRIMEA; GLADSTONE; PITT.

English Snipe, a name among American sportsmen for the common American snipe (*Gallinago delicata*).

English Sparrow. See HOUSE SPARROW.

Engrafting. See GRAFTING.

Engraving, the execution of works of art on plates intended for printing. Impressions from metal plates are named engravings, prints, or plates; those printed from wood being called indifferently wood engravings and wood-cuts.

Engraving on wood, intended for printing or impressing from, long preceded copperplate engraving. It is to Germany we are indebted for the choicest specimens of early wood engraving; and among these the works of Albert Durer stand pre-eminent for delicate yet spirited execution.

The first English engravers on wood worthy of notice are Edward Kirkall, born in 1695, and John Baptist Jackson, who died in 1754. But the art had no real vitality in England until the brothers Bewick, about the close of the 18th century, founded the English school of wood-engraving, which has since attained a position second to no other.

Copperplate engraving arose in the 15th century. Until then the art of engraving on metal had been confined to decorating sacred vessels, armor, services of plate, etc., with emblematic figures, and other pictorial and ornamental devices.

Although the earliest use of engraved copper plates for printing impressions on paper has been claimed for German artists, it is now generally agreed that the practice was first established by the Florentine goldsmith and engraver, Finiguerra, an impression from one of his works having been recognized as produced in 1440, the date of the earliest German print being 1460. The new art had, however, very soon spread over Italy and Germany, for before the close of the century many eminent engravers had risen in both countries.

A perceptible change in style about the end of the 17th century marks the rise of the modern continental schools of engraving. Since then the artists of France, Italy, and Germany, have rivaled each other in producing many noble specimens of their skill and industry.

Great Britain possesses no early engravers in the simple style worthy to rank with the continental masters; and it was not until the middle of the 17th century that a few English and naturalized foreign artists, by their successful cultivation of the compound process, gave an impulse to the art, which had hitherto languished in complacent mediocrity. The succeeding century produced many native engravers who contributed to raise the British school to high eminence. The most celebrated of these, Sir Robert Strange and William Woolet, may be regarded as the founders in Great Britain of the styles in which they respectively excelled.

In proceeding to describe the methods and the instruments employed in the different styles, we give precedence to line-engraving, not only on account of its demanding greater manipulative skill, and that in it the highest triumphs of the art have been achieved, but also because a description of the tools and many of the processes will include those used in most of the other branches.

Line-engraving.— As implied by the term this is executed entirely in lines. The tools are few and simple. They consist of the graver or «burin,» the point, the scraper, and the burnisher; an oil-stone or hone, dividers, a parallel square, a magnifying lens, and a blind, or shade of tissue paper, to make the light fall equally on the plate. For leveling important erasures there are used callipers, a small steel anvil, a small pointed hammer, and punches.

On commencing a plate, the first procedure of the engraver is to make a careful outline of his subject upon thin paper, with a black-lead pencil. The next step is to lay the «ground» on the plate; and an essential preliminary is to thoroughly cleanse its surface. Copper is effectually cleaned by a mixture of fine whiting and turpentine spread over the heated plate, and when the turpentine evaporates, wiping off the whiting with clean rag. The most efficient means of cleaning a steel plate is a strong lye, or solution of the common black ashes of the shops, and turpentine. With this mixture the plate is repeatedly washed, and each time rinsed with cold water; finally, it is rubbed dry with a scrupulously clean cotton rag. The hand-vise is now attached to one corner of the plate, a small thick fold of paper protecting the face at that part; then the plate is laid face upward on a moderately hot iron; or, better still, a tin box filled with water, kept boiling by a charcoal stove, or spirit-lamp beneath. By this latter contrivance all risk of burning the ground, and thus making it unfit for etching, is avoided. When the plate is hot enough, the ball of etching ground is rubbed over the surface, the heat causing it to melt and ooze through its wrapper of silk. The ground is then spread by light and rapid strokes with the rounded face of the dauber, continued until every part is thoroughly covered with an equal thin coating. The ground must now be smoked while the plate is hot, by holding it face downward, and passing the flame of two or three wax tapers loosely tied together, rapidly to and fro and across its surface, till it becomes a clear shining black: but care must be taken not to burn it, by permitting the flame to rest an instant on one place. The plate being cooled the paper on which the outline is drawn is damped, placed carefully face downward on the plate, and secured in its position by small bits of bordering wax; another piece of paper, also damped, is next laid over it, and the whole passed through the roller-press used for printing plates. When the paper is lifted off, the pencil outline is found transferred in reverse to the shining black surface in clear silvery lines.

Etching.— To protect the outline and ground during this process, supports made of paper, wood, or leather, about one eighth of an inch thick, are fixed on the margin; resting on these the parallel square is laid across the plate for the two-fold purpose of supporting the hand and of guiding the point. In a landscape, outlining and etching in the parts go on simultaneously; but in an historical piece the outline must first be secured by dotting it in carefully with the point, and then all parts of the subject it is desirable to etch are proceeded with.

When the etching is completed the supports are taken off, and the bridge — a thin board, having cross pieces about one inch thick under each end — is laid across the plate to support the hand. The margins are then painted over with varnish of brunswick black thinned with turpentine, the entire surface of the ground carefully examined, and all breaks or scratches penciled over with the varnish which resists acid equally with the ground. When this hardens, a wall of bordering wax about an inch high is placed round the subject, and pressed firmly down on the plate to retain the acid which is now applied. It must be borne in mind that the spaces between the lines, however narrow, and all parts not touched with the point, are protected from the action of the acid by the ground. Nitrous acid mixed with three or four parts water and a little sal ammoniac is used to corrode copper. When poured on, small bubbles of fixed air rise out of and collect upon the lines; these must be continually brushed off with a soft feather, otherwise foul or irregular biting ensues. A quarter of an hour generally suffices to corrode the lightest parts to a sufficient depth and breadth. The acid is then poured off, the surface of the plate washed with clean, cold water, and gently dried with blotting paper, or by the wind of a pair of bellows. The light parts being protected by varnish, acid is again poured on, and the process is repeated till all the successive degrees of dept. are obtained.

The biting-in being accomplished, a proof is taken preparatory to the next step toward completion. Finally, the burnisher is brought into play alternately with the graver and point, to give the last finish to all parts.

An almost incredible amount of laborious and carefully minute graving is required in a highly finished historical plate to bring out the proper effects of form, texture, relief, and to impart to it the unity, breadth, and mellowness of effect essential to a highly finished engraving; but many proofs and retouchings are necessary ere a satisfactory result is obtained.

Painters' or Amateur Etching.— This art is a favorite pursuit with amateurs and little practice in the use of the graver and dry point suffices for finishing this description of work.

Aquatinta.— This method, as first practised and still followed, has been already described. See AQUATINTA.

Mezzotinto.— This process differs fundamentally from all other styles of engraving on copper or steel, inasmuch as in it the lights and gradations are scraped and burnished out of a prepared dark ground, whereas in other methods the shading is corroded or cut into a blank surface.

The Mixed Style.— This is based on mezzotinto, which, still forming the great mass of shading, is in this method combined with line and stipple in such proportions as the taste of the artist suggests. All the tools employed in other styles are required for this; the roulette being largely used in subordinate parts.

Engraving on Wood.— See WOOD-ENGRAVING.

Mechanical and Photographic Process.— Engraving in recent times has suffered much from the rivalry of photographic and mechanical substitutes. The most important of these is known as photogravure or heliogravure. The beauty of the work produced by means of this process in the reproduction of paintings, of drawings in monochrome made for the purpose, and of photographs direct from nature, has raised it to a position of great importance. A photo-mechanical process which is much used in the reproduction of the plates of the older engravers and etchers, and in the production of intaglio etched plate-reproductions from pen drawings has been carried to great perfection, some of the work produced being almost equal to the finest original etchings. A positive photograph is taken of the drawing or engraving to be reproduced (that is, the lines are black, the whites clear glass); this is placed over a copper plate coated with a bituminous varnish, and exposed to the light. Where the lines of the photograph have protected the varnish from the light it remains soluble, but where the light has affected it through the glass it becomes insoluble. The varnish may then be dissolved from the lines and the copper exposed exactly as if the etching point had been used to make the drawing on an etching ground. The plate is then bitten in the usual manner, and finally touched up and improved with the graver. See PHOTO-ENGRAVING.

Engrossing, an act which, on ancient statute books, when the natural laws of trade were little understood, and political economy not even guessed at, was set down as a crime. It consisted in something similar to what nowadays is known as "cornering the market" by buying up the crops or the herds wholesale (Fr. *en gros*) before they were fit for use, in order to retail them at a great profit when they matured and were available for consumption. The offense was not only a statutory offense in England, but a crime in common law, and from the time of Edward VI. to that of Queen Anne laws were repeatedly passed for its repression. Even in the last century a prosecution for engrossing was witnessed in an English law court. In acts 7 and 8 Victoria, ch. 24, the offenses known as forestalling, engrossing, and regrating, or retailing at a profit, were abolished. In recent years there has been a good deal of litigation in the United States, and much discussion all over the civilized world with regard to the legality of corporations formed for the express purpose of monopolizing the trade in certain necessities or luxuries of life. See COMBINATIONS; MONOPOLY, RESTRAINT OF TRADE; TRUSTS.

The term is also used to denote the careful transcription of a deed, statute, or other legal document, in large hand; and is often applied, in the United States, to the final and certified copy of a statute, which is ready to be signed by the President, or the governor of a State.

Enharmon'ic (from Gr. ἐναρμονικός, in accord) in Greek music, a mode little known about, but distinguished by the use of small intervals or quarter tones, such as the tetrachord of which the first two steps were quarter steps and the third a major third. In modern music used as a general term to denote a difference in degree but not in pitch, though specifically there is a slight variation of pitch, which the same note takes according to its adjustment to a fundamental *tonic*. Thus C♯and D♭ are practically the same note on keyed instruments, yet strictly speaking, the former should be produced by 15-16 of the whole string sounded, the latter by 9-10. An enharmonic change of key, that is shifting from one scale to another, as in transposing C♯to D♭, often enables a composer to write more easily by avoiding recurrent accidentals.

Enhuber, ĕn'hoo-bĕr, **Karl von,** German painter: b. Hof, Bavaria, 16 Dec. 1811; d. Munich 6 July 1867. He studied at Munich, at first being known as an animal painter and later applying himself to romantic and humorous themes. He was made an honorary member of the Munich Academy 1858, and wears the order of St. Michael. Among his works are: 'The Dying Gunner'; 'Poachers'; 'Smoking Boy'; 'Interrupted Game of Cards'; 'Grandfather's Delight'; 'Wood Carver in His Shop'; and 'Stage Coach at the Tavern.'

Enkhuizen, ĕnk'hoi-zĕn (Lat. *Enchusa*), Holland, a town on a projection in the Zuyder Zee, 29 miles northeast of Amsterdam. It was once a place of great importance and had an extensive commerce, and a population of 40,000. Pop. 7,050.

Enna, ĕn'a, or **Henna.** See CASTROGIOVANNI.

En'neking, John Joseph, American painter: b. Minister, Ohio, 4 Oct. 1841. He studied at Munich and Paris, and was a pupil of Bonnat and of Daubigny. He paints chiefly landscapes and figure paintings. He received honorable mention at the Paris Exposition of 1900, and among his works are: 'Moonlight on the Giudecca, Venice' (1876); 'Freshly Picked'; 'Drove of Cattle on a November Day' (1878); 'The Obersee'; 'Farmyard Scene in France'; 'November Twilight' (1881); 'Summer Twilight' (1883); 'Indian Summer' (1885); 'The Coming Storm'; and 'Springtime.'

Ennemoser, Joseph, yō'sĕf ĕn'ĕ-mō-zĕr, Austrian medico-philosophic writer: b. Tyrol 15 Nov. 1787: d. Egern 19 Sept. 1854. He fought in the rising of the Tyrolese against the French 1809. After the Peace of Paris he went to Berlin, where he finished his studies and, 1816, took his degree in medicine. In 1819 he became professor of medicine at the new University of Bonn. In 1841 he went to Munich, where he obtained great reputation by the application of magnetism as a curative power, and published several works on that subject.

Ennery, Adolphe Philippe De, ä-dōlf fē-lēp dĕn-nĕ-rē, French dramatist: b. Paris 17 June 1811; d. there 26 Jan. 1899. He began life as a clerk, but later turned to the drama; studied scenic effects, the quick change from the tragic to the comic, and the contrast between the serious and ludicrous characters. He subsequently became the master of modern melodrama, producing alone and in collaboration some 200 plays. During the 50 years of his active life he accumulated a fortune of $1,200,000. His most successful plays include: 'Taking of Peking'; 'Mary Jane' (1845); 'Two Orphans' (1873); 'Martyrdom'; 'The Grace of God'; 'Grandmother.'

Ennes, Antonio, än-tō'nē-ō ĕn'nās, Portuguese dramatist: b. Lisbon 1848. He was for some years prominent in journalism, and afterward held high government offices. His first play, 'The Lazarists,' had extraordinary success in Portugal and Brazil, and long held the stage. It was followed by the comedy 'Eugenia Milton' (1874), and the dramas 'The Troubadours'; 'The Mountebank'; 'The Emigration'; 'A Divorce.' The last was translated into Italian and French.

En'nis, Ireland, town, in county Clare, on the Fergus, 19 miles northwest of Limerick. It contains a Roman Catholic college and Ennis College, founded by Erasmus Smith. O'Connell's monument and the ruins of a 13th century Franciscan abbey are among its attractions. A considerable trade in grain, flour, and agricultural produce is carried on, and large fairs and markets are held. Pop. 5,460.

Enniscorthy, ĕn-is-kôr'thĭ, Ireland, town, in the county of Wexford, situated on the river Slaney, 77 miles south of Dublin. There is an old castle erected by one of the early Norman conquerors, and in the neighborhood is Vinegar Hill, the scene of a skirmish in 1798 when the town was stormed by the rebels. The river Slaney is navigable, and there is a considerable trade in provisions. Pop. 5,648.

Enniskil'len, Ireland, a borough and market town of county Fermanagh; 37 miles northeast of Sligo; on an island in the river Erne, which connects the upper and lower sections of Lough Erne. Suburbs are on the adjoining mainland. In its town hall are kept the flags of the battle of the Boyne. The battle of 1689, between the forces of James II. and William III., in which William's forces were victorious, took place here. The noted regiment called Enniskillen Dragoons, or 6th Dragoons, were first formed from the defenders of the town at this battle. The manufacture of cutlery, straw hats, shirts and collars, and the tanning of leather are carried on here, and the trade is considerable. Pop. 5,570.

En'nius, Quintus, Latin poet: b. Rudiæ, near Brundusium, 239 B.C.; d. 169 B.C. When he was 38, Cato the Censor brought him to Rome, where he soon gained the friendship of the most distinguished men, and instructed the young men of rank in Greek. With an extensive knowledge of the Greek language and literature he united a thorough acquaintance with the Oscan and Latin tongues, and exerted great influence on the last. He wrote an epic poem in hexameters, 'The Annals'; tragedies and comedies; satires, epigrams, precepts, etc., but nothing now remains but fragments given as quotations in other ancient authors, many of them mere citations by grammarians and other insignificant extracts. A few larger fragments have been preserved, which give a favorable impression of his genius. His success in his own day was great. His poems were for a long period read aloud to admiring multitudes, and they were often quoted and referred to by the great writers of antiquity. See Sellar, 'Roman Poets of the Republic.'

Enns, ĕns, river in Austria, has its rise in the Alps of Salzburg, flows north-northeast, and then takes a northwesterly course into the Danube. Length about 160 miles. It divides Austria into Upper Austria and Lower Austria.

E'noch, Hebrew patriarch. He became the father of Methuselah at the age of 65 years; and we are told that he "walked with God," and at the age of 365 years "God took him." The words quoted are generally understood to mean that Enoch did not die a natural death, but was removed as Elijah was. The book of Hebrews (xi. 5) confirms this view. Enoch is the name of three other persons in the Bible, one of them being the eldest son of Cain (Gen. iv. 17).

Enoch, Book of, an ancient apocalyptic work in the Ethiopic language, of an assumedly prophetical character, of considerable importance on various accounts, and particularly because of its quotation by St. Jude in the 14th and 15th verses of his epistle. It is referred to by many of the early fathers, and Tertullian believed it to be canonic. Latterly it became discredited, and finally was lost to the Western Church, being known in Europe only by the references of these and other early writers. Bruce, the celebrated traveler, in 1773, discovered two Ethiopic manuscripts of it in Abyssinia, where it was still extant, and brought them home with him. Other manuscripts were subsequently found, and it has since been repeatedly translated and criticised in Europe, the Ethiopic text having also been published. The best translation (with commentary) is that of Prof. Charles: 'The Book of Enoch' (1893). According to him 'The Book of Enoch' as translated into Ethiopic belongs to the last two centuries B.C. All the writers of the New Testament were familiar with it, and were more or less influenced by it in thought or diction. The Ethiopic version was translated from the Greek, but the original was in Hebrew or Aramaic. It consists of revelations supposed to have been made to Enoch and Noah. These refer to the state of future blessedness, to judgments upon the wicked, and to the coming of the Messiah. They are full of elaborate imagery founded on the Book of Daniel and other portions of the Old Testament, upon which the dogmatical teaching of the Book of Enoch is also founded. Prof. Charles regards it as having been based on five separate treatises, which were fused together and modified in various ways, the final editor having made use of a lost apocalypse, called the Book of Noah. See 'Encyclopædia Biblica,' Vol. I. (1899).

Enoch Arden, a narrative poem by Alfred Tennyson (1865). Its theme is the return of a shipwrecked mariner to his home after a lapse of several years, only to find that his wife has married in his absence, believing him dead.

Enomo'to, Buio, Japanese statesman: b. Tokyo. He was educated in Europe, and returning to Japan in 1867, became the first president of a republic which he established in the island of Yego, but was ousted by the Japanese army 1869. After imprisonment for two years, he was appointed vice-admiral in the Japanese navy 1874. He served as minister plenipotentiary to Russia and became a member of the council of state and minister of education 1888, minister of foreign affairs 1891, and minister of agriculture and commerce 1892, which office he held for four years.

Enos, ā'nōs, Turkey, town on the north coast of the Ægean, 70 miles south by west of Adrianople. Pop. 7,000.

Enriquez Gomez, Antonio, än-tō'nē-ō ĕn-rē'kĕth gō'mĕth (properly ENRIQUEZ DE PAZ), Spanish poet; son of a converted baptized Portuguese Jew: b. Segovia early in the 17th century. He entered the army in his 20th year, and rose to the rank of captain; but in 1636 fled to Amsterdam, and, having there professed the Jewish faith, was in 1660 burned in effigy at a Seville auto-da-fé. The date of his death is not known. For his 22 comedies, of which some passed as Calderon's, and his poems, consult Ticknor, 'History of Spanish Literature.'

Enschede, ĕns'нā-dĕ, Holland, town in the province of Overyssel, 30 miles east-northeast of Zutphen. Rebuilt since its destruction by fire in 1862, it has large yarn- and cotton-mills. Pop. 16,178.

Ensenada, ĕn-sā-nä'dä (Spanish, a creek, cove, or bay), Argentina. (1) Seaport in the province of Buenos Ayres, the port of La Plata. (2) Seaport of Mexico, in the northern part of Lower California, on the Pacific coast, at the head of the Bay of Todos los Santos.

Ensign, the flag or colors of a regiment, in England, consisting of a field of white, blue or red, with the union in the upper corner, near the staff. Of naval ensigns the white flag is confined to the royal navy, the red to the merchant service, the blue to the naval reserves. In the American navy the ensign is the national flag, and it is also flown by the merchant service. In England, up to 1871, the lowest grade of commissioned officers in a regiment of infantry, by the senior of whom the regimental ensigns or colors were carried. The name is now abolished, the title of 2d lieutenant being substituted for it. Also the title of the lowest grade of commissioned officers in the United States navy.

Ensilage, ĕn'sĭ-lāj. See SILAGE.

En'statite, a native silicate, chiefly of magnesium, but also containing more or less iron and aluminum. The mineral commonly occurs in massive or fibrous forms, but distinct crystals, prismatic in habit, and belonging to the orthorhombic system, are also occasionally found. Its color varies from white to green. Its hardness is 5.5, and its specific gravity about 3.2. Enstatite is a common constituent of peridotites, crystalline schists, and meteorites, and is also associated with certain serpentines. It belongs in the pyroxene group, is insoluble in hydrochloric acid, and before the blow-pipe it fuses only along its thin edges. The name (Greek, "adversary") refers to these refractory qualities.

Entab'lature, in architecture, the horizontal, continuous work which rests upon a row of columns, and belongs especially to classical architecture. It consists of three principal divisions, the epistyle or architrave immediately above the abacus of the column, next the frieze, and then the cornice. In large buildings projections similar to and known also as entablatures are often carried round the whole edifice, or along one front of it.

En'tada, a genus of leguminous plants containing about a dozen species of climbing tropical shrubs, remarkable for the great size of their pods. *E. scandens* has pods which measure from six to eight feet in length. The seeds have a hard, woody, and beautifully polished shell, and are often made into snuff-boxes, scent-bottles, etc.

Entail′, the settlement of an estate so that it shall pass according to a certain rule of descent. In England after the Norman Conquest estates were frequently granted to a man and the heirs of his body, but in time the law courts interpreted such grants as conferring a fee simple conditional, so that when the condition, namely the begetting of an heir, was fulfilled, the estate became a fee simple absolute and could be alienated by the grantee. The statute ‹De Donis Conditionalibus,› passed in 1285, declared that this interpretation was contrary to the intention of the grantors, and enacted that in all future grants of this nature the grantee should have no power to alienate the estate, and that on the failure of issue the land should revert to the grantor. The effect of this statute was to prevent the free conveyance of land, but gradually the lawyers created a series of proceedings, known as fines and recoveries, by means of which a tenant in possession could bar the entail and convert his estate-tail into a fee simple, that is, into his absolute property. (See FEE, ESTATE.) These remedies created by the courts were abolished by the Fines and Recoveries Act, passed in 1833, and a direct means of barring entails was introduced. This statute enacts that every actual tenant-in-tail shall have full power to dispose of, for an estate in fee simple absolute, or for any less estate, the lands entailed, but a tenant-in-tail in remainder, expectant on an estate of freehold, cannot bar the entail, though he may bar his own issue, without the consent of the «protector of the settlement,» who is usually the tenant for life.

Entasis, ĕn′tā-sĭs, in architecture, the delicate outward curve of a column, found in perfection in the Doric column, by which an arc is described whose highest point is about midway between capital and base. This swelling of the column is intended to counteract the optical error by which a rigidly straight perpendicular line has a tendency to appear concave. The entasis is also calculated to suggest life and motion in the column under the superimposed weight of the entablature.

Entelechy, ĕn-tĕl′ĕ-kĭ, a Greek word meaning «the bringing to completion»), in the peripatetic philosophy of Aristotle is the transition or connecting action between what he calls **δύναμις**, potentiality, and **ἔργον**, actuality; that which, among the schoolmen, is conceived as intervening between the *posse,* and the *esse,* for example, between the infinite possibilities of omnipotence in the Supreme Being, and their manifestation in creation and active providence.

Entel′lus Monkey, or **Hoonoomaun,** an anthropoid ape or monkey included in the family *Simiadæ.* Its general name is *Semnopithecus, pithecus* standing for ape, and the rest of the word signifying sacred, or holy. This name has reference to the superstitious veneration in which the animal is held by the people in the land of its nativity. The specific name *entellus* contains the idea of command, and may refer to its head-dress, suggesting a reason for the worship it receives. In structure the animal conforms to the features which mainly distinguish the Old World monkeys from those of the New World, among which characters are: (1) the downward direction of the nostrils; (2) the presence of an opposable thumb; and (3) a non-prehensile tail. The body measures 22 inches, the tail 38 inches, and the weight is about 20 pounds. The color of the body is light yellow, the outside surface of the limbs chocolate, the hands and feet black. The hair radiating from a point on the forehead forms a crown for the head and a visor to protect the eyes. The range of this species is restricted to the southwest provinces of the river Ganges in India. Although the hoonoomaun is supposed to embody the spirit of a deceased human ancestor, its habits are mischievous and destructive, and it commits great havoc where it is protected.

Entente Cordiale, ŏṅ-tŏṅt kôr-dĭ-ăl, in politics, a term used in international politics, signifying a certain cordiality, based either upon sentiment or community of interest between nations and rulers. It is a relation closely bordering upon an alliance.

Enteralgia, ĕn-tē-răl′jĭ-ạ. See ENTERITIS.

Enter′ic Fever. See TYPHOID FEVER.

Enteritis, an inflammation of the small intestine, the most important symptom of which is diarrhœa. Different varieties of enteritis are described as catarrhal enteritis, the acute enterocolitis of children, or cholera infantum, croupous enteritis, and enteritis due to tuberculosis, carcinoma, and other malignant diseases. In primary enteritis the symptoms may be acute or chronic, the most important single symptom being diarrhœa. The stools are thin and watery, and particles of undigested food may be found in them. There is usually colicky pain with gas, and occasional vomiting. Loss of appetite, thirst, and dry tongue are usually present, but fever is not common. The general causes of catarrhal enteritis are improper food, particularly in children, unripe fruit, toxic substances, changes in the weather, and nervous influences bringing about changes in the character of the secretions and in the muscular activities of the walls of the intestines. Infectious diseases may also be the cause of acute enteritis. Rest in bed, following a mild laxative such as calomel or castor oil, together with milk diet, will usually be sufficient treatment for the simple cases.

Acute enteritis of infants, known as cholera infantum (q.v.), is a much more serious disease. This is a form of dysentery, in which not only the small intestine but the large intestine also is involved, and the most active cause of this disease is a specific micro-organism called the bacillus of Shiga. Treatment of acute enteritis of infants requires trained medical advice. The most important feature, however, in infants is to cut down the feeding, giving practically nothing but water for at least 24 to 36 hours. See CHOLERA INFANTUM; COLITIS; DYSENTERY; INTESTINES, DISEASES OF.

Enteroclysis, a form of intestinal hydrotherapy of much importance. It consists in lavage of the intestines. The ordinary hot-water enema is the simplest form of enteroclysis, but true enteroclysis consists in continuous irrigation with large quantities of solution, either with a single or a double tube. The effect of the introduction of large amounts of hot salt solution (a dram of common table-salt to a pint of water, at a temperature of from 110° to 118° F.) is very marked. There is much increase in the tension of the pulse, and pronounced stimulation of the heart-action, both of prime importance in the treatment of hemorrhage, shock, asphyxiation from drowning or from coal-gas poisoning, and of many forms of drug and industrial poisoning. Enteroclysis has also a marked effect in augmenting the secretion of the kidney, and proves of immense importance in the treatment of chronic uræmic poisoning, such as is seen in Bright's disease, and also in the treatment of diabetic coma. It is likewise of importance in bladder troubles, in colitis, in peritonitis, septic endocarditis, and in ulcerative conditions of the large intestine, such as are found in dysentery and in cholera. Enteroclysis is also an excellent mode of treating collapse in chronic alcoholism.

En'terprise, The, an American 12-gun schooner with a brilliant naval career; one of the steadily "lucky" vessels. Built 1799 to deal with the French privateers in the West Indies, she had an extraordinary cruise in 1800: in a six-months' run she took 8 privateers, some of them much heavier than herself, and aggregating 47 guns, besides recapturing 4 American merchantmen. Sent to the Mediterranean against the Barbary pirates, she captured a 14-gun Tripolitan after a fierce engagement, and later was at the bombardment of Tripoli. But her finest battle was with the English brig Boxer, Capt. Blythe, on 5 Sept. 1813, off the Maine coast, toward Monhegan Island. She had then 16 guns, and was under Lieut. William Burrows; the Boxer had 14. The crews were about 100 each. The fight began at 3.20 P.M., and was ended at 4 by the Boxer striking, literally cut to pieces in hull, masts, rigging, and spars, several of her guns dismounted, boats and quarters shattered; while the Enterprise was almost uninjured, with but one shot in the hull and one in the mainmast. Both commanders were killed. American loss, 2 killed, 10 wounded; British, 4 killed, 17 wounded.

En'toderm (also called entoblast or hypoblast), the innermost layer of cells in the developing embryo. In man it subsequently develops into the epithelium that lines the digestive canal and its appendages, the pancreas, liver, lungs, etc. See EMBRYOLOGY.

Entomological Societies. Half a century ago a single entomological society was all that had been organized in the United States, but at the present time there are probably upward of a score of organizations devoted to this science. The first entomological society of which we have record was formed in 1842, and was The Entomological Society of Pennsylvania, which has long been out of existence. The American Entomological Society of Philadelphia was founded in 1860 under the name of The Entomological Society of Philadelphia, and published 'Proceedings' until 1868, when the society name was changed and the publications became known as 'Transactions.' This, as well as some of the other societies that will be mentioned, is supported by a permanent endowment fund, owns very extensive and valuable collections and a library, which are deposited with the Academy of Natural Sciences of Philadelphia, of which institution its members are associate members of the entomological section. Under the combined auspices of these organizations there is now published 'Entomological News,' which completed its 13th volume in 1902. The Entomological Society of Ontario publishes the 'Canadian Entomologist' which has reached its 35th volume and annual reports. It began publication in 1868, though the society had a previous existence under the name of The Entomological Society of Canada. It is supported by an annual government grant of $1,000 and the sale of its publications. The Brooklyn Entomological Society was organized in 1872, and in 1888, while retaining a corporate existence, became merged in the Brooklyn Institute, forming the department of entomology of that institution. It published 7 volumes of a 'Bulletin' and 6 volumes of 'Entomologica Americana,' but has temporarily discontinued publication. The Cambridge Entomological Club was founded at Cambridge, Mass., in 1874, and publishes 'Psyche,' a quarterly originally devoted largely to bibliographical and biological entomology. The same year The Entomological Club of the American Association for the Advancement of Science was formed. In 1884 The Entomological Society of Washington was organized, publishing 'Proceedings.' The Association of Economic Entomologists, as has previously been mentioned, was established in 1889. Its 'Proceedings' are published in the general series of bulletins of the Division of Entomology of the United States Department of Agriculture. In the year 1881 The New York Entomological Club began the publication of 'Papilio,' but at the end of its 4th volume its members joined the Brooklyn Entomological Society. In 1892, however, another society was organized in New York as The New York Entomological Society. It was incorporated in 1899, and issues a quarterly 'Journal.'

In addition to these, the principal publishing entomological associations of the United States and Canada, there are several entomological sections of larger scientific societies in Canada and in the United States. There are also local clubs or societies in various sections, for example, in Newark, N. J.; at Williamsburg, N. Y.; at Chicago, Pittsburg, and in San Francisco, the home of the California Entomological Society.

There are many foreign societies, nearly all of the largest cities of Europe supporting one or more, usually holding titles significant of an entire nation, for example, there are entomological societies of Belgium, France, Switzerland, Russia, Italy, and Germany, and others representing the cities of London, Berlin, Vienna, and Stockholm. See also AMERICAN ENTOMOLOGICAL SOCIETY.

Entomology, the science which deals with insects. See INSECTS.

Entomology, Economic. Attacks by insects upon useful plants doubtless began with the first cultivation of plants. But it was not until the end of the 18th century that any means for mitigating their ravages were employed beyond hand methods and other purely mechanical measures. A few crude efforts were made among the ancient farmers and fruit-raisers on the shores of the Mediterranean toward the suppression of insect-pests, and Pliny even advised the use of white hellebore, one of the modern insecticides; but it was at about the middle of the 19th century that insecticides

(q.v.) or insect poisons began to be generally adopted, and the migration of the Colorado potato beetle from its native home in the Rocky Mountain region to the potato fields of the East was the indirect means of the employment of arsenical preparations as a means of destroying insects; so that this insect, while an apparent curse, has proved, indirectly, of the greatest value to the agricultural community at large. Prior to the use of Paris green, which appears to have first been applied to this potato pest in Michigan in 1867, knocking the beetles from the infested plants into a pan of water, was the only method of treatment, and was used for many other insects as well. The discovery of the value of this poison as a remedy for the codling moth was made in 1878, by Prof. A. J. Cook, who used Paris green as a remedy for canker-worms, and found that the trees treated with it were free from codling moth. To Prof. Cook also is probably due the first use of kerosene mixed with soap, although the kerosene emulsion, which is now a standard remedy for all sucking insects, was the joint product of Messrs. Barnard, Hubbard, and Riley, and first used in 1877. White arsenic was employed as an insecticide as early as 1871, and London purple was put to practical use in the destruction of the cotton-worm in 1878. London purple has since been displaced by various other insecticides, as it has proved inferior to Paris green, which, in turn, has been replaced by arsenate of lead, because the latter, while poisoning the insects, does not scald or otherwise injure the plants. In the same manner that the discovery of Paris green as a remedy for the Colorado potato beetle was made through the migrations of this insect, the ravages of the cottony cushion scale (*Icerya purchasi*) of the orange orchards of California led to experiments conducted by Mr. D. W. Coquillett, of the United States Department of Agriculture, in 1886, to the finding of hydrocyanic-acid gas as the best medium for extirpation of scale insects (q.v.), and to its general use in fumigation for all insects which can be treated with it. In 1895 Messrs. A. F. Woods and P. H. Dorsett, also of the Department of Agriculture, began experiments which led to the adoption of a perfected system of fumigation with the same gas of plants grown under glass and injured by scale and other insects.

Our best remedies for insects, then, arsenical mixtures and kerosene emulsion and other preparations, and hydrocyanic-acid gas, are the product of American research. The bisulphid of carbon as an insecticide, however, though the discovery of a foreigner, has doubtless received greater attention in our country than elsewhere. It was first employed by M. Doyere, as early as 1856, as a remedy for weevils in stored grain, which is still its principal use; but its cost when first employed was so excessive as to preclude its general employment on a large scale. Subsequently a high grade of this chemical, known as "fuma-bisulphid," was made for sale at 10 cents a pound. It supplements the use of hydrocyanic-acid gas in that the former is used for the fumigation of plants above ground, while the latter destroys insects affecting the root-system. Both gases are used for the treatment of indoor insects in granaries and mills, and in dwellings and ware-houses. Although these are the main insecticides there are others, nearly all of which owe their discovery and perfection to economic workers in America. They include pyrethrum, better known as Buhach, Persian, and Dalmatian insect-powders, the extensive use of which has resulted in the establishment of a considerable industry in the growing of the principal plants which produce these powders (*Pyrethrum cinerariæfolium* and *Pyrethrum roseum*); and whale-oil and fish-oil soaps, originally used against the hop-plant louse in 1886, and later against scale-insects. In more recent years what is now termed the "lime, sulphur, and salt wash" has been found a very valuable remedy against scale-insects.

During the early years of work in spraying for various insects the principal dependence was placed in American insecticide machinery, but after the invention of different forms of nozzles by M. Vermorel, of France, various other nozzles, pumps, and other machinery were invented in America and have gone into general use.

Prevention of Insect Injuries by Farming Methods.— It would be difficult to detail step by step the wonderful progress that has been made in means of subduing insects by simple farming methods which, as a rule, necessitate little or no extra labor or monetary outlay. Some of our principal pests, with which we cannot cope successfully by means of insecticides or by mechanical methods, may be controlled by the judicious use of ordinary methods of tillage. The seed, nursery, or other stock for planting should be selected with a special view to securing immunity from attack by the insect most feared or most prevalent in the region where the crop is to be planted. By planting different immune varieties of wheat the ravages of the Hessian fly are reduced to a minimum. Certain forms of trees may be selected for planting for shade in some regions without danger of injury, because the insects which elsewhere do greatest damage to them are not present. The selection of a suitable location on the farm for a crop should be made with the same end in view. Where injury is feared by an insect which does not travel freely, immunity can be secured by planting in that part of the farm where the insect is known not to exist. The prompt destruction of crop remnants, and the pulling up and burning over of weeds and other rubbish, is a preventive applicable to all crops. Another measure is the use of "trap crops." Thus part of an old crop may be left to attract insects which usually remain in the field after the crop is made; similar or more attractive plants may be grown for the protection of the main crop; or of early varieties of the same plants, as lures for the insects until the main crop can obtain a good start. Trap crops are of considerable value in the treatment of several of the worst enemies of cucumbers, melons, squashes, and similar vines. The stimulation of a plant by means of fertilizers, and the maintenance of healthy, vigorous growth by cultivation, the suppression of diseases, and the prevention of injury by insect pests other than those which it is specially designed to circumvent, are helpful aids. Crop rotation, or the planting of alternate crops which are not injured by those insects which ravage the staples assists in the warfare; as also do fall and spring plowing, which, in proper combination, result in the destruction of nearly all forms of the many insects which pass one or more stages in the earth in hibernation. The use of water by irrigation or submersion, if practised at the right time, will result in the temporary extirpation of nearly all insects in the fields thus treated, particularly in cranberry bogs. The reclamation by drainage of land subject to more or less complete submersion, such as swampy tracts, river bottoms, and the like, and the destruction of the weeds and other plants and the insect life which remain by burning over, are of great value in suppressing many pests. If, to the methods above outlined, we add the strict observance of timely harvesting of crops with a view to the prevention of further attack and the destruction of insects which might reproduce the following year; the utilization of natural enemies, such as parasitic and predaceous insects, poultry, and live stock, to destroy the insects in the field after the crop is off; the systematic inspection of the farm for the first appearance of insect attack, and, finally, the co-operation of neighboring farmers, there is comparatively little use for insecticides save in the case of insects such as grasshoppers and the caterpillars of moths and butterflies, which are strong fliers and cannot be successfully controlled by mechanical methods.

Economic Entomologists.— Dr. T. W. Harris is credited with having been the first economic entomologist of this country, but in reality the honor is due to W. D. Peck, who began writing on injurious insects late in the 18th century (1795–1819). His writings, however, are few, in comparison to those of Harris, whose labors began in 1831 and whose greatest work appeared in 1841, his classic treatise on 'Insects Injurious to Vegetation.' In the year 1853 the New York State legislature appropriated $1,000 for the study of economic entomology, and Dr. Asa Fitch was appointed to perform the work specified. Fitch's work continued until 1871 or 1872, when his 14th and last report was published. Afterward different States, Illinois in 1866–7, and Missouri about a year later, appointed State entomologists, the latter State obtaining the services of Dr. C. V. Riley, who wrote a series of nine reports which, for originality, scientific accuracy, and practical value, have received recognition the world over.

When Dr. Riley assumed the duties of entomologist of the United States Department of Agriculture, economic entomology received a new impetus, his work and that of his assistants marking a new era in practical entomological work. Upon his death in 1894, he was succeeded by Dr. L. O. Howard, under whose direction the Division of Entomology continues to issue reports, bulletins, and circulars of the highest practical and scientific value. See AGRICULTURE, DEPARTMENT OF.

Prior to 1888 Massachusetts, New York, Illinois, and Missouri, were the only States which maintained officially appointed economic entomologists. During that year the State Agricultural Experiment Stations (q.v.) were organized under the Hatch Act, and several official entomologists were appointed in connection with them. In 1889 was formed an Association of Economic Entomologists which held annual meetings in various cities subsequently and had in 1903 a total membership of 167. A list of the addresses of the presidents at each meeting is appended. Together they form a history of the progress of applied entomology in America.

Entomos'traca, one of the two great subclasses of crustacea (the other is Malacostraca) including minute forms, the "water-fleas," having a horny shell of many pieces, a well-developed cephalo-thorax, mandibles, and three pairs of maxillæ, five pairs of thoracic feet, but no abdominal feet, and no gills, breathing instead by specialized organs. They have a great variety of shapes and of means of locomotion. The young is a nauplius and develops by numerous molts. The group includes many thousands of species divided into four orders,— *Phyllopoda, Ostracoda, Copepoda,* and *Cirripedia* (barnacles). They abound in stagnant fresh waters, and also in the sea, and furnish an immense quantity of subsistence for fishes that are used for human food. They exist and increase in innumerable

millions. The descendants of a single cyclops may in one year number over 4,000,000,000. At one time they render the surface of the sea-water phosphorescent by their vast luminous congregations. At another time the Atlantic Ocean is colored red over a space of hundreds of square miles by the assemblage of these minute creatures, attracting multitudes of fishes, even of whales, which feed upon them. On the other hand, some forms are equally injurious as parasites. These belong chiefly to the copepod group, *Siphonostomata,* having mouths fitted for suction. Some are commensal, entering the gill-sac or the digestive cavity and feeding upon the food, not upon the tissue of the host. Some attach themselves long enough to suck the blood of their victim and then pass on; while others enter the body as permanent residents and embed themselves in the tissue. Thus they are the pests of starfish, jellyfish, worms, ascidians, fishes, and whales. See BARNACLE; COPEPODA; CRUSTACEA; FISH-LICE; OSTRACODA; PHYLLOPODA.

Entozo'a, formerly employed as the name of a subdivision of radiate animals, has passed out of use as a term of systematic classification, because it fails to indicate or signify any ideas of structure, and only hints at the habitat and occupation of great number of living creatures. Following the strict meaning of the word, entozoa, denoting "animals within" other animals, not only brings together many genera that belong with the different subdivisions of the same general division, but also imports those which are included under classes morphologically distinct. Even this use of the term is liable to confusion, as it excludes many kinds of parasites which attach themselves to other animals, living upon their juices and tissue, without entering the cavities of the body. Of such are the whole troupe of mites which embed themselves within the skins of their hosts. (See EPIZOA.) The common bot-fly, *Gastrophilus equi,* is taken in at hatching time with the food of the horse, and, passing the larval stage of nine months in the stomach of the host, is discharged, to enter upon the adult stage, unless meantime the horse dies as the result of the great number of the guests. The degraded barnacle, *Peltogaster paguri,* attaches itself permanently to the exposed abdomen of the hermit-crab, deriving its sustenance from the host, but feeding upon rather than within the body of its victim.

The present use of the term entozoa is artificial, and tends to restrict its application (following Cuvier in this respect, though for convenience only) to that section of the class *Vermes,* known as platyhelminths or anneloids, a group of lower grade than the true worms, or annelids. All parasitic animals are degraded in structure because the field and manner of their life makes no demand upon higher and more specialized organs. In the class *Platyhelminth,* embracing the following described forms, are the planarians which are not parasitic, and the flukes and tapeworms, which are both parasitic and injurious. The difference between the former and the two latter illustrates one of the most interesting facts in biology. The planarians, leading a free and non-sessile life, are provided with sense-organs and organs of locomotion and defense which equip them for the exigencies of an active, competitive life; the parasites, on the contrary, are destitute of any such outfit or of any effective tools, save hooks or suckers for holding their anchorage, and the simplest instruments for boring into and for eating their hosts. In the free stage of life they abound in fresh water or salt, and in moist conditions. Of the sub-class *Trematoda* are the flukes, very large in numbers, which pass through most interesting changes in development, their habitat and organs varying with each successive stage. The larva, after leaving the egg, swims freely, enters the body of its host, changes form, and becomes the parent of a number of the second generation; these may remain until they mature, or in some species they may, during the progress of their metamorphoses, infest three different hosts. During these transitions the larva enjoys a commensal existence, feeding on the food swallowed by the host; but having reached the adult stage it lives by destroying the tissue in which it is moored. *Distomum hepaticum* or liver-fluke, which is found in fresh water, is a case in point. Its life moves in a circle. As an adult it inhabits the liver of mammals. The eggs there produced are discharged through the intestines into the outer moisture, where they hatch. The larva takes to the water and swims until it attacks a particular snail, *Lymæus trunculatus,* into which it enters; assumes the form of a sac or cyst, which soon produces a tadpole; the snail crawls out among the grass, and leaves this cercaria, which shakes off its tail and becomes encysted on a spear of grass. Finally, a sheep eats the grass, the cyst is dissolved, and the adult worm, three quarters of an inch long, buries itself in the sheep's liver. It is found in the liver of many ruminants and of other animals, including man. Many trematods abound in the sea, infesting cuttlefish and cephalopods. *Cestoda* is the subclass of tapeworms, which infest and work destruction in nearly all vertebrate animals. The form is elongate and flat, like a ribbon or tape, and the tapeworm is divided into sections — proglottids — forming a chain. Their manner of life has resulted in almost complete organic degeneration, as they have neither organs of locomotion nor a digestive canal, merely absorbing the juices of the host through the pores of their skin. There are two types: *Ligula,* having only a partially divided body; and *Tænia,* completely jointed, and each joint containing eggs for reproduction. The head is small, about the size of a pin, and is crowned with a ring of about 25 hooks, by which the worm anchors in the walls of its host's intestine. See TAPEWORM.

In the case of *Tænia solium* the larva must be twice swallowed, each time by a separate host. A pig takes in the egg mixed with its food. A cyst or cysticercus is formed and enters the tissue, producing "measly pork," which may be eaten by human beings, transferring the cysticercus to an attachment in the alimentary canal of the new host. In *Tænia echinococcus* the reverse process holds. The larval stage is passed within a human or other animal, while the adult appears in the dog or some other domestic animal. This parasite sadly afflicts the Icelanders, and appears to result from their uncleanly habits and from the large number of their dogs, these latter communicating the pests to plants gathered for food. Other species of *Tænia* are parasitic in dogs and sheep, promoting in the latter the disease commonly called «staggers.» The largest specimens of the cestod group belong to the family *Bothriocephalidæ*, which hold their mooring by two suckers on the head. The length of these worms sometimes reaches 30 feet.

The filiform, or threadworms, belong to the division *Nematoda*. *Filaria sanguinis-hominis* is referred to as the cause of elephantiasis, a disease common in Oriental tropical climes. The disease is said to be spread by the mediation of mosquitoes, which suck in the larvæ with the blood of the patient whom they bite. Then, when depositing their own eggs in the water, they die, setting free the threadworm embryos, the progeny of which are transferred to the human system through drinking the water. The nematoid trichina is the most dangerous of human parasites, finding its way into the body through the eating of pork, the larvæ having been developed in swine. After the meat has been swallowed the cyst containing the larva is dissolved in the digestive process; the larva is released, becomes mature, reproduces in multitudes of young, which make their way into the muscular tissue, where again they mature and may remain for years. Thorough cooking kills the larvæ in the pork. (See TRICHINA SPIRALIS.) Allied to trichinæ is *Trichocephalus dispar*, which is sometimes found in the human colon. Some genera of *Strongyllidæ* attack the human body, but other genera are the despair of poultry-raisers. *Syngamus trachealis* enters the respiratory passages of fowls, and produces the «gapes.» The afflicted bird, by coughing, expels the eggs of the parasite, which mingle with food and are eaten by other fowls, and the disease becomes epizootic. On the first discovery of the infection the afflicted subject should be isolated. *Ascares* is the nematoid known as the pinworm, and is a human entozoon of universal distribution. The eggs, being light, are easily distributed. In the human system they develop to the adult form. Happily this pest, and all others of the entozoan kind, rapidly diminish as public and domestic cleanliness, sewerage, and sanitary plumbing increase. The class *Anthrocephali* or spine-headed worms, enter pigs, fishes, and other animals as intestinal guests, and are said sometimes to afflict man. The proboscis is armed with barbs, like those of the tapeworm, by which the guest fastens itself in the tissues. The larval stage is supposed to be passed in the body of some aquatic animal. See also PARASITES.

Entre-Douro-E-Minho, ĕn'trĕ dō'roo ē mĕn'yoo, a province of Portugal, more generally known by the shorter appellation of Minho. Pop. (1900) 1,173,106.

Entre Rios, ĕn'trā rē'ōs, Argentine republic, a province bounded on the north by Corrientes, on the east by the republic of Uruguay, on the south and west by the provinces of Buenos Ayres and Santa Fé. As its name indicates, its territory lies «between the rivers»— Rio Paraná and Rio Uruguay. Area 45,000 square miles. Agriculture and immigration have been encouraged by the provincial government, which sells land to settlers in portions of 82½ acres, to be paid for in three years, at prices ranging from $600 to $2,000, according to location. In 1880 there were 32 agricultural colonies; in 1885 there were 54; 122 in 1891, and so on. The cultivated area in 1887 was 248,411 acres; in 1891 it had increased to 855,000 acres. This increase is noticeable especially in the area devoted to wheat, the quality of that product being uncommonly good. Other products are: Maize, lucerne, barley, flax, grapes, tobacco, fruit, and (on a very large scale) cattle, sheep, and horses. Its capital, the city of Paraná (population 20,000), was the capital of the republic from 1852 to 1861; it has a national college, a normal school, and several elementary schools, and is an important port for the traffic on the Paraná River. Population of the province more than 300,000.

Entrecasteaux, Joseph Antoine Bruni d', zhō zĕf äṅ twän brü nē dōṅtr-käs-tō, French navigator: b. Aix 1739; d. at sea near the island of Waigeoo 20 July 1793. He entered the naval service in 1754, gradually rose to the position of commandant of the French fleet in the East Indies (1786), and in 1787 became governor of Mauritius and the Isle of Bourbon. In 1791 he was sent by the French government in search of La Pérouse, who had not been heard from since February 1788. He failed in detecting any trace of him, but ascertained with great exactness the outlines of the east coast of New Caledonia, west and southwest coast of New Holland, Tasmania, and various other coasts. The D'Entrecasteaux Archipelago was named in his honor.

Entresol, ŏṅ tr-sŏl or ĕn'tėr-sŏl (Fr. «between the floors»), a low story between two of greater height, generally the ground and first stories. It is called also the Mezzanine.

Entro'pion, or **Entropium,** inversion or turning in of the edge of the eyelids, in consequence of which the lashes rub on the eyeball, causing annoyance and pain.

En'tropy, in thermodynamics, a certain mathematical expression whose value does not change when the substance under discussion undergoes a reversible compression or expansion, while not receiving any heat from external sources, nor giving any up to them. In general, the change of entropy that a body experiences when it passes from one state to another by a reversible process, is found by dividing the heat that the body absorbs during every infinitesimal part of the process of transformation by the absolute temperature of the body at the corresponding instant, and integrating the results. The term entropy does not appear to admit of any simpler explanation than has here been given; and, in fact, while the conception of entropy (which we owe to Clausius) is a valuable and almost indispensable aid in advanced thermodynamics, it has always proved a stumbling-block to the beginner. The entropy of a body, unlike its temperature, cannot be obtained by direct observation, but must always be inferred by the process given above, or by some graphical method equivalent to it. The transformation that a body undergoes when its entropy does not change at all is called an «adiabatic» or «isentropic» change. See THERMODYNAMICS.

Entry, Right of, the right of taking possession of lands or property by entering or setting foot on the same. This may be done either by the claimant personally, or through his agent or attorney.

Entry, Writ of, a formal declaration made by one exercising the right of entry in recovering property of which he has been disseized that he claims full possession of the said property. The common law action of Writ of Entry has some time been obsolete.

Ent'wistle, James, American naval officer: b. Paterson, N. J., 1837. He entered the engineering service United States navy 1861, became commander in 1888, and in 1899 was made captain and rear-admiral and was placed upon the retired list. He first served on the Aroostook under Farragut in the Western Gulf squadron, and on 21 other vessels, was inspector of machinery at the Bath (Maine) Iron Works 1890–5, while the ram Katahdin and the gun-boats Machias and Castine were in process of contruction, and assistant to the general inspector at Mare Island Navy Yard in 1895. He joined the Asiatic squadron at Yokohama during that year, being appointed fleet engineer 1897 and assigned to the Olympia. He took part in the battle of Manila Bay, 1 May 1898, being advanced in numbers for meritorious services upon that occasion.

Envelope, a paper case, sealable by means of an adhesive flap, and used for enclosing letters or other matter. Envelopes were not in general use in any country prior to 1840, when, after the passage of the penny postage bill, they became common in England. Until about 1845 nearly all letters in this country were folded so that an unwritten portion came on the outside, and the address was placed there. By that time envelopes were well known, and by 1850 all letters were enclosed in them. The first maker of envelopes in New York was an Englishman named Dangerfield, who began about 1846; and by 1850 Alderton and several others were in the field. Only 2,000 or 3,000 could be made in a day, as machinery had not yet been employed. The blanks were cut out by chisels and pasted and folded by hand. Machines were invented in England in 1845 by Warren de la Rue and Edwin Hill, but these were never employed in America. The machinery employed for this purpose in the United States was invented here, but not until just before the outbreak of the Civil War. Many improvements have been made, and the speed is now so great that on some of the machines the output will reach 55,000 a day. It is supposed that the consumption of envelopes in this country is from 8,000,000 to 10,000,000 a day, or not far from 3,000,000,000 a year, of which 600,000,000 are stamped envelopes. The latter are all supplied by the Morgan Envelope Company, of Springfield, Mass., and the Plimpton Manufacturing Company, of Hartford, Conn. There are about 30 large firms engaged in the business, besides a number of smaller manufacturers. The principal towns thus employed are New York, Philadelphia, Hartford, Rockville, Holyoke, Worcester, and Springfield.

Envir'onment, a modern scientific term applied to the modifying influences of an organism or surroundings. Neither plant nor animal can be understood as a rounded-off unity; the whole life or function is made up of action and reaction between the organism and its environment. Streams of matter and energy from without preserve the relative constancy of the organism, as of a special wave-crest in the sea; while changes in the streams have their corresponding changes within the organism. The plant or animal has obviously a strong unity of its own, but even that is in part due to ancestral welding under the hammers of the environment. It may seem, too, to vary of itself like a fountain in the air, but throughout all its rises and falls there blows the wind of the environment.

The influence of outside conditions has been recognized by most naturalists from the time of Hippocrates, and is taken for granted in our everyday speech and action. There is considerable difference of opinion, however, as to the importance and degree of this influence. Thus Buffon, Treviranus, and Geoffroy St. Hilaire regarded the surroundings as directly hammering changes on the organism; while to Erasmus, Darwin and Lamarck internal changes arose as indirect functional results of new environment. Charles Darwin allowed a measure of truth in both these positions, but emphasized the independent action of the organism itself in the direction of natural selection. These three positions are still held, some emphasizing one, others another, the majority combining the three. See DARWINIAN THEORY; EVOLUTION.

Envoy, a person deputed by a sovereign or government to negotiate a treaty, or transact other business, with a foreign ruler or government. We usually apply the word to a public minister sent on a special occasion or for one particular purpose; hence an envoy is distinguished from an ambassador. Envoy extraordinary and minister plenipotentiary is a permanent resident abroad, in some unimportant country officially representing his government, but of inferior rank to an ambassador.

Enzina, Juan de la. See ENCINA, JUAN DEL.

En'zyme (Gr. "leavened"), any of the unorganized ferments, such as diastase, cytase, trypsin, etc., which induce fermentive changes in organic substances. It was formerly thought that these "unorganized" ferments might be essentially different in their action from the so-called "organized" ferments, such as the yeasts, molds, and bacteria; but it is now known that the fermentive action of the "organized" class is due chiefly, and perhaps wholly, to the enzymes that they secrete. The chemistry of the enzymes is very imperfectly understood. According to some authorities they act merely by catalysis, being capable of effecting the fermentive change of indefinite quantities of the substances upon which they act, without being themselves used up, nor exhausted in any way. According to other authorities, they are gradually destroyed by their own activity, so that a definite mass of any given enzyme can produce only a definite (though surprisingly large) amount of fermentive transformation. See FERMENTATION.

Chemical ferments, elaborated in the cells of plants and animals, and capable of bringing about a peculiar series of biochemical reactions, which are produced without the intervention of physical factors or mineral substances. Under some conditions they have the properties of facilitating chemical interchanges between certain bodies without entering into the composition of the different products that result.

These enzymes, or ferments, zymases, or diastases, as they are frequently called, play an important role in the digestive processes, as well as being of vital importance in the general life-history of nearly all plants. A knowledge of enzymes dates back to very remote periods. In the beginning of the 16th century observations on the phenomena of digestion called attention to this class of bodies; but it remained for Dubrunfaut and Pasteur to place the science of fermentation on a stable basis. Enzymes are for the most part soluble in water, being thrown out of solution by a large number of chemical substances, such as alcohol, tannic acid, etc. They usually lose their activity at a temperature above 100° F. Most of them decompose hydrogen peroxide, and they act largely in proportion to their quantity. With reference to their chemical composition, it would appear that they belong to the proteid class. There is usually a large proportion of inorganic salts, particularly calcium phosphate, in their composition. A few, however, do not contain nitrogen. Although closely related to proteids, they do not give proteid color-reactions. As to their formation, it is considered by some that they are oxidation products of albuminoid substances, or zymogens. The transition of the zymogen into the ferment is termed zymogenesis. Destruction of enzymes is termed zymolysis. As to the manner of action of this interesting class of bodies, a vast variety of phenomena may be observed. They may bring about molecular changes either by hydration or by oxidation. They appear to occupy the position of intermediaries, as it were. Many thories are put forward in attempting to explain the action of enzymes; but as they present many analogies to living protoplasm, explanation of the phenomena of their activities is almost as difficult as to explain the phenomena of life. Attempts have been made to classify the various enzymes, but any classification must be of a transitory character, since knowledge concerning this group of bodies is increasing daily. The classification of the soluble ferments suggested by Effront is shown below.

The enzymes have many applications in the arts. Consult: Greene, 'Soluble Ferments'; Effront, 'Enzymes and Their Applications,' John Wiley, N. Y., 1902.

Eocene (ē'ō-sēn) **Epoch** (Gr. «dawn»), a term applied in geology to one of the divisions of the Tertiary, as originally suggested by Lyell; a geological period. See EOCENE SERIES; TERTIARY.

Eocene Series, a subdivision of geological time. Lyell in 1833 first used the term Eocene (dawn of the recent) for the earliest of his

CLASSIFICATION OF SOLUBLE FERMENTS.

Names of the Enzymes.	Substances on which the Enzymes Act.	Products of the reaction.
	A. SOLUBLE HYDRATING FERMENTS.	
	1. Soluble Ferments of Carbohydrates.	
Invertin or sucrase	Cane-sugar	Invert-sugar
Amylase	Starch and dextrin	Maltose
Glucase or maltase	Dextrin and maltose	Dextrose
Lactase	Lactose	Dextrose and galactose
Trehalose	Trehalose	Glucose
Inulase	Inulin	Fructose, levulose
Cytase	Cellulose	Sugars
Pectase	Pectin	Pectates and sugars
Caroubinase	Caroubin	Caroubinose
	2. Soluble Ferments of Glycosides.	
Emulsin	Amygdalin and other glycosides	Glucose, oil of bitter almonds, and hydrocyanic acid.
Myrosin	Potassium myronate	Glucose and allyl isosulphocyanate
Betulase	Gaultherin	Oil of wintergreen Glucose
Rhamnase	Xanthorhamnin	Rhamnatine, isodulcite
	3. Fatty Ferments of Fatty Substances.	
Steapsin } Lipase }	Fatty substances	Glycerin and fatty acids
	4. Soluble Ferments of Proteins.	
Rennet	Caseinogen	Casein
Plasmase	(Casein, Hammarsten)	(Para casein)
Casease	Fibrinogen	Fibrin
Pepsin	Casein	
Trypsin	Albuminoid substances	Proteoses, peptones
Papain	Albuminoid substances	Proteoses, peptones, amides
	5. Ferments of Urea.	
Urease	Urea	Ammonium carbonate
	B. SOLUBLE OXIDIZING FERMENTS.	
Laccase	Uruschic acid Tannin, anilin, etc.	Oxyuruschic acid Products of oxidation
Oxidin	Coloring matters of cereals	Products of oxidation
Malase	Coloring matters of fruits	Products of oxidation
Olease	Olive oil	Products of oxidation
Tyrosinase	Tyrosin	Products of oxidation
Oenoxidase	Coloring matter of wine	Products of oxidation
	C. FERMENTS CAUSING MOLECULAR DECOMPOSITION.	
Zymase or alcoholic diastase	Various sugars	Alcohol and carbonic acid

three subdivisions of the Tertiary. The term found favor quickly since early Tertiary life differed greatly from late cretaceous. Toward the close of cretaceous time, the sea receded from a large part of North America and by the end of Eocene time the continent had nearly its present form. Though the climate continued warm, Greenland and Alaska having a temperate climate, yet the elevation of the land must have affected the direction of prevailing winds and modified rainfall. Of cretaceous animals the reptiles suffered most, the ichthyosaurs, dinosaurs, and plesiosaurs passing away as well as many peculiar mollusks. Eocene fishes were mostly of modern character (teleosts), birds were more numerous and highly developed than in the Cretaceous Age; while mammals developed wonderfully. True carnivorous mammals (cynodictis) appeared, as also the ancestors of the horse (*Hyracotherium*), rhinoceros (*Heptodon*), tapir (*Systemodon*), pig (*Eohyns*), and the ruminants (*Trigonolestes*), besides bats, primitive camels (*Leptotragulus*), and monkeys (*Anaptomorphus*). A study of organic types indicates that Asia, North America, and Europe were connected in Eocene time and, by the Antarctic continent, South America, and Australia, while South America was separated from North America and Africa and southern Asia from Europe and northern Asia.

The Eocene formations in the United States are classified geographically as the Atlantic border, Gulf border, interior and Pacific border provinces. The Eocene rocks of the Atlantic border are nearly all loose sands and clays of marine origin and contain in New Jersey beds of greensand once of some economic importance as a source of phosphate of lime for agricultural use. The rocks of the gulf border were partly laid down in fresh or brackish water and partly in salt water. They comprise shales, sandstones, and limestones. In Florida are valuable deposits of phosphate rock, and in Texas are extensive beds of lignite, of workable size, but poor quality. The series is divided into the (1) Midway, (2) Lignitic, (3) Lower Clairborne, (4) Clairborne, (5) Jackson, and (6) Vicksburg stages. The interior province formations, mostly clays and sands, were laid down in brackish or fresh water lakes which stretched, though not contemporaneously, from Mexico to Alaska. The largest of these lakes covered eastern Utah, and western Colorado, and must have been 450 miles long and 250 miles wide. In Utah are lignite deposits of some importance. The lake deposits are divided into the (1) Puerco, (2) Wasatch, (3) Bridges, and (4) Uintah stages. In the Pacific border province the Lower Eocene stages are wanting and the epoch is represented by a single series, the Tejon, shales and sandstones with workable deposits of lignite in California and Oregon. See CENOZOIC ERA; GEOLOGY; TERTIARY SYSTEM.

Eohippus, ē-ō-hip'ŭs, a genus of fossil horses of the Eocene Epoch, with four complete toes in the fore foot and three in the hind foot, and with slender bony rudiments (splint-bones) representing the missing innermost digit in the fore foot and the outermost digit of the hind foot. The teeth are short-crowned, the premolars of simpler pattern than the true molars, and the molar cusps are incompletely converted into crests. The animal was as large as the domestic cat, and probably a direct ancestor of the horse. Its remains are found only in the Lower Eocene of North America. See HORSE, FOSSIL.

E'olus («the varied one»), in Greek mythology, god of the winds.

Eon de Beaumont, ā-ôn dė bō-mōn, **Charles Geneviève Louis Auguste André Timothée d'** (called till 1777, CHEVALIER D'EON), French writer, military officer, diplomatist, and publicist: b. Tonnerre 5 Oct. 1728; d. London 21 May 1810. His brilliant qualities enabled him to act a conspicuous part in the world, but he gained a greater notoriety by the mystery long kept up in regard to his sex. In 1755 he was sent as envoy on a difficult mission to the Russian court. Here he gained the favor of the Empress Elizabeth, and for about five years was the medium of a secret correspondence between her and the king of France. In 1762 he went to London as secretary of legation and lived for years in London as a kind of informal representative of his sovereign. In 1777 he returned to France, but Louis XVI., for what reason is not known, imposed on him the obligation of assuming female attire, and he now styled himself La Chevalière d'Eon. Even before this, however, doubts as to his real sex had arisen. After the French Revolution broke out, he offered his services to the National Assembly in 1792, was rejected, and went back to England. He now attempted to support himself by giving lessons in fencing (still dressed as a woman), but was not very successful, and depended for subsistence mainly on his friends. He was rather a voluminous writer, and his works appeared in 1775 under the title 'Loisirs du Chevalier D'Eon.'

Eos, ē'ŏs. See AURORA.

Eosinophiles, ē-ō-sĭn'ō-fīls, one of the types of leucocytes or white blood-cells found in the circulating blood and characterized by its specific reactions to acid stains, such as eosine, whence its name — «a lover of eosine.» Eosinophiles are present in the proportion of one half to two per cent of the white blood-cells. Their increase above two per cent is termed eosinophilia, and it has an important relationship to some forms of parasitism.

Eosinophil'ia, a condition in which there is an excess of eosinophile white blood-cells in the circulating blood. The exact causes of eosinophilia are not thoroughly understood. But it seems to be an almost constant accompaniment of certain diseases, notably of infection by intestinal parasites. So it is in trichiniasis, in anchylostomiasis, and in infection by the ordinary tapeworm. Consult: Ewing, 'Pathology of Blood' (1902).

Eōthen, ē-ō'thĕn, or **Traces of Travel Brought Home from the East,** a noted work by Alexander William Kinglake, published in 1844. Eōthen — a title meaning «From the Dawn» — is a lively and acute narrative of travel in the East, at a time when that region was comparatively new ground to English tourists. The author, starting from Constantinople, visits the Troad, Cyprus, the Holy Land, Cairo, the Pyramids, and the Sphinx; thence by the way of Suez he proceeds to Gaza and returns by the way of Nablous and Damascus. He apologizes for his frankness of style, and gives his impressions with refreshing directness, modified as little as possible by conventional opinion.

Eötvös, ĕt'vėsh, **Joseph**, Hungarian statesman and author: b. Ofen 3 Sept. 1813; d. Pesth 3 Feb. 1871. He completed his studies in philosophy and law at the University of Pesth in 1831, and before leaving the university, produced three dramas — 'Kritikusok,' 'Házasulók,' and 'Boszú' — the last a tragedy, all of which were well received. He published an important work on the reform of prisons (1838); became a friend of Kossuth, and distinguished himself as a journalist and in the diet. A collection of his political writings was published in Leipsic in 1846. He continued to give his leisure to literature, and published a succession of novels — 'The Carthusian' (1841); 'The Village Notary' (A'falu' jegyzöje, which has been translated into English), 1844–6; 'Hungary in 1514' (1847–8) — giving vivid pictures of Hungarian life in modern and more remote epochs. After the revolution of 1848 he became minister of public instruction under Batthyani, but soon retired to Munich, and remained in voluntary exile for three years, during which he published several works, among which was 'The Influence of the Ideas of the 19th Century on the State of Society' (1851). About the middle of 1851 he again returned to Hungary, where he was made vice-president of the Hungarian Academy in 1855, and president in 1866. In 1867 he again became minister of public instruction.

Eötvös, Roland, Hungarian scientist and statesman: b. 27 July 1848. He is a son of Joseph Eötvös (q.v.). He studied at Konigsberg and Heidelberg, receiving an appointment as lecturer at Budapest 1871 and as professor of experimental physics there 1875, being made a member of the Hungarian Academy of Sciences 1873, and becoming its president in 1893. Much of his attention has been given to the problems of gravitation and capillary attraction. He was made a life member of the Hungarian House of Magnates and was minister of public worship and education 1894–5.

Eozoic (ē-ō-zō'ĭk) **Era** (dawn of life), the Geologic Period during which life first appeared on the earth. The eozoic rocks, though often showing traces of organic origin, have in general been greatly metamorphosed and contain few, if any, fossils. Stratigraphically they are separated from the Archæan (or Azoic) rocks below and the Cambrian (or earliest Palæozoic) rocks above by unconformities, but the exact boundaries of the Eozoic are disputed by geologists. See ALGONKIAN SYSTEM; GEOLOGY; HURONIAN SERIES; KEWEENAWAN SERIES.

Eozoön, ē-ō-zō'ŏn. Sir J. W. Dawson, in 1864, described certain curious aggregates of calcite and serpentine in the Laurentian limestone of the lower St. Lawrence Valley as the remains of a foraminiferan which he called Eozoön Canadense. The so-called fossil was thought to represent the earliest known form of life on the globe. The evidence of organic origin is, however, not conclusive. Similar forms have been found in Bavaria. Moebius, who investigated Eozoön thoroughly, concluded that the serpentine in the calcite had infiltrated along a very regular system of fine fissure, and most geologists now believe that Eozoön is of inorganic origin.

Epacridaceæ, ĕp-a-krĭ-dā'se-ē, a small order of heath-like shrubs or small trees, usually reckoned as the Australian sub-order of *Ericaceæ*, from which they are chiefly distinguished by the epipetalous stamens destitute of the peculiar specializations of anther dehiscence or appendages. The flowers are red, white, or purple, generally in leafy spikes. Many species are cultivated in greenhouses along with the heaths proper. Among the most attractive of these is *E. grandiflora*, which has blossoms nearly an inch in length, of a brilliant reddish purple at the base and pure white at the apex. A few species produce edible berries resembling the American huckleberry, and which are known as Australian cranberries.

E'pacts (Gr. «additions»), in ecclesiastical chronology, a set of 19 numbers used for fixing the date of Easter and other Church festivals, by indicating the age of the moon at the beginning of each civil year in the lunar cycle (q.v.). At the reformation of the calendar in 1582 it was found that the Golden Numbers could no longer by themselves serve the purpose of adjusting the double reckoning by lunations and by the tropical or true year; and thus, instead of adopting the more rational computation, the Roman Church devised the artificial and involved method of epacts. The main point to determine is the age of the moon (in entire days) at the beginning of each civil year, or the number of days between the end of the ecclesiastical year in December and the first January succeeding. Thus, subtracting 354 days (12 lunations) from 365, we should have 11 days for the first annual epact, then 22 for the year following, then 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, and 29; the series of 19 numbers being obtained in succession by adding 11, and when the sum exceeds 30, subtracting that number. This illustration, however, is simpler than any actual case, by reason of the leap-years, which require 12 to be added for the following epact, and of the fact that no lunation is exactly 30 days long. When the lunar cycle of 19 years is completed, the epacts recur again in the same order. In the Anglican reckoning, as distinguished from the Roman, it is noteworthy that the Gregorian epact for any year is the same as the Julian epact for the year preceding, owing to the coincidence that 11, the number of days lost on the Julian account before the English parliament adopted the reformed calendar (q.v.), is also the number of days between the lunar and the solar years. The epact determines by subtraction the date of the first new moon in January; then by adding 29 and 30 alternately the successive new moons throughout the year are assigned to their respective dates. Consult Delambre, 'Astronomie Moderne,' Vol. I. 4–32.

Epaminondas, ē-păm''ĭn-ŏn'dăs, Theban hero: b. about 418 B.C.; d. Mantineia, Arcadia, Greece, 362 B.C. He was distinguished for the friendship subsisting between him and Pelopidas. He was sent to Sparta 371 B.C. to represent Thebes in negotiating a peace with the Athenian envoys. As the Spartans refused to recognize Thebes as the representative of Bœotia, the Thebans were excluded from the peace. Cleombrotus was sent by the Spartans to invade Bœotia, but was defeated at Leuctra (371 B.C.), chiefly through the tactics of Epaminondas. Two years after Epaminondas and Pelopidas were made Bœotarchs. They detached several nations from the alliance of Lacedæmon, and delivered the Messenians, whose capital they rebuilt. Epaminondas then marched with his army to Sparta; but this city was so bravely and skilfully defended by Agesilaus that the Theban hero retreated. An accusation was brought against him on his arrival in Thebes, because he and Pelopidas had kept the Bœotarchate beyond the legal time; the accusation was literally true, but the infringement of the law was justified by his services, and after having pleaded his own cause, he was acquitted. In 368 he compelled Sicyon and Pellene to relinquish the Lacedæmonian alliance, and in the same year served in a Theban army sent into Thessaly to rescue Pelopidas, who was kept a prisoner at Pheræ. In the following year he commanded an expedition with the same object which was successful. In 362 he was compelled to make head against a formidable coalition of states, including Athens and Sparta. His tactics were never more brilliant and successful than in this campaign, but in the battle of Mantineia he was killed at the moment of victory.

Ep'aphus, the son of Jupiter and Io, who caused Phaëton's destruction by denying his divine descent.

Ep'arch (ἔπαρχος *eparchos*), an ecclesiastical term formerly in use as equivalent to archbishop or metropolitan. In the national Russian Church bishops are all called eparchs as well as bishops, as in English they are currently styled «ordinaries» (Lat. *ordinarii*) and «diocesans» (Lat. *diœcesani*). The sees or territorial jurisdictions of bishops in the Russian Church are eparchies.

Epaulement, ĕ-pâl'mĕnt, in fortification, a term originally employed to denote a mound of earth, raised to protect a body of troops at the extremity of their line; or a screen or rampart erected, as a sort of shoulder, to defend the flank of a battery from enfilading fire, which would dismount its guns. In modern artillery, the word is applied to the whole mass of earth, stone, or fascines raised to protect a battery both in front and at the flanks. It is also used of the breastwork set up to shelter reserve artillery.

Epaulet, ĕp'â-lĕt, an ornamental badge, consisting of a fringe hanging over the shoulder, worn in the English army up to 1855, and still worn in the English navy by all ranks above lieutenant. Epaulets were not partially discarded by the United States army until 1872, when none but general officers continued to wear them. In the United States navy the epaulet is worn by all officers above the rank of ensign. The French private soldiers wear epaulets of worsted.

Epée, Charles Michel, shärl mē-shĕl ā-pā, **Abbé de l',** French instructor of the deaf and dumb: b. Versailles, France, 25 Nov. 1712; d. Paris 23 Dec. 1789. Taking orders, he became a preacher and canon at Troyes, but later lived in retirement in Paris. In 1765 he first began to occupy himself with the education of two deaf and dumb sisters; and, as he asserted, without any previous knowledge of Pereira's efforts in the cause, invented a language of signs, by which persons thus afflicted might be enabled to hold intercourse with their fellow-creatures. He determined to devote his life to the subject. At his own expense he founded an institution for the deaf and dumb, which was first publicly examined in 1771, and from 1778 received an annual subsidy. It was not, however, converted into a public institution till two years after his death.

Epeira, ĕ-pī'ra, a genus of spiders, typical of the family *Epeiridæ*, comprising some of the largest and best-known spiders, those building orb-webs. They occur in all parts of the world, and are usually handsomely marked. See ORB-WEAVER, and SPIDER.

Epenceph'alon, one of the names to signify one of the primary stages in the development of the embryo brain. See BRAIN.

Eperies, ā-pār'yĕs (Slovak *Pressova*), Hungary, an old town on the Tarcza, 150 miles northeast of Budapest. It is the seat of a Greek Catholic bishop, and has a college, with 500 students. It manufactures earthen-ware, linens, and woolens, and has some trade in corn and Tokay wine; in the vicinity are the Sovar salt-works. Pop. 10,439.

Epernay, ā-pĕr-nā, France, in the department of Marne, in the midst of a rich vine-growing district; 19 miles northwest of Chalons. The earthen-ware called terre de Champagne is made in Epernay. Pop. 20,512.

Ephah, ē'fa, a dry measure of capacity among the ancient Hebrews, corresponding with the liquid measure bath. The ephah contained about 36 litres French, equal to 9½ gallons of the United States, or 8 gallons British. There were, however, two measures called ephah, of which the above estimate applies to the larger, and this contained one third more than the other.

Ephedra, ĕf'ĕ-dra, a genus of shrubs used for decorative purposes in landscape gardening. In general appearance they resemble the horse-tails. The flowers are small and inconspicuous. The species occur in all parts of the world, but are not hardy, and need protection from frosts. They flourish best in dry or rocky soils, and are easily propagated. Their fruit is said to be mucilaginous, eatable, sub-acid, and slightly pungent. The branches and flowers of the Asiatic species were formerly sold as styptics.

Ephem'era, -fem'e-rä, the typical genus of the insect family *Ephemeridæ* (q.v.).

Ephemeridæ, ĕf-ē-mĕr'ĭ-dē, a family of neuropterous insects characterized by the slenderness of their bodies: the delicacy of their wings, which are erect and unequal, the anterior being much the larger; the rudimentary condition of the mouth; and the termination of the 10-jointed abdomen in 3-jointed filiform appendages. The adult May-flies, or day-flies, as they are called, emerge from the chrysalis on the banks of the running streams in which the eggs are hatched, and, appearing usually toward sunset, are no less remarkable for their great activity than for their enormous numbers, and the brief period of their existence. The eggs, which are shed in a mass, drop into the water. The larvæ have elongated depressed bodies; setose antennæ, and long caudal filaments; and lamellar or tufted gills, symmetrically disposed on either side of the abdomen. They remain in the water for a year or two before undergoing further change, lying beneath stones, and leading a predaceous life, for which their strong jaws fit them. The rudiments of wings mark the commencement of the nymph stage, at the close of which they crawl out of the water, and cast the nymph integument. Their sexual immaturity prior to the second molt has led to their being named, at this stage, subimagos or pseudimagos. The larvæ, which are very similar throughout the family, are largely used as bait. There are many species in various parts of the world, divided into various genera. *Ephemera* and *Cœnis* have three caudal filaments; *Palingenia* and *Cloë* only two, but the larvæ have three. The posterior wings are absent in *Cloë* and *Cœnis*.

Ephem'eris, an astronomical almanac. The plural Ephemerides is applied to tables showing the places where the planets and heavenly bodies are found at noon of every day. It is from these tables that eclipses, conjunctions, etc., of the planets are determined. See ALMANAC (*Nautical*).

Ephe'sians, the Epistle to the, one of the books of the New Testament. It seems to have been sent by St. Paul to the people of Ephesus about 62 A.D., while he was a prisoner in Rome (Eph. iii. 1, iv. 1). He sent it to its destination by the hand of Tychicus (Eph. vi. 21). The Church at Ephesus had been founded by Paul himself, or at least he had raised it from the feebleness in point of numbers and knowledge in which it had been when he commenced his missionary work in that city. For two years he preached Christ, not merely to the permanent residents in Ephesus, but to the multitudes who resorted thither as pilgrims to visit the celebrated temple of Diana, then one of the wonders of the world (Acts xix. 10). When driven from the city, owing to a riot raised by one whose craft would have been in danger had idolatry fallen, he retained a deep interest in his converts; and, despatching Tychicus to inquire after their welfare (Eph. vi. 21), gave him the canonical 'Epistle to the Ephesians,' for the Church just named, with another to the Church at Colossa (Col. iv. 7). It is evident from the 'Epistle to the Ephesians' that the converts at Ephesus were mainly Gentiles (Eph. ii. 11, iii. 1), and prominent in the didactic part of the letter is the doctrine that Christ had broken down the middle wall of the partition which severs Jew and Gentile, putting both on the same level of privilege within his Church (Eph. ii. 11–22, iii. 1–6). The Epistle concludes with a series of practical exhortations.

Ephesus, ĕf'ĕ-sŭs, Asia Minor, a Greek city of Lydia; one of the 12 Ionian cities; near the mouth of the river Caystrus, now called Kutshuk Mendre. Ephesus is now represented by the village of Ayasoluk, about 36 miles from Smyrna, on the railroad to Aïdin. After belonging to the Ionians, it fell successively under the dominion of the Lydian and Persian kings. Its importance as a commercial city dates chiefly from the time of Alexander the Great. The apostle Paul lived for two years at Ephesus and established a Christian Church there, to which he addressed one of his epistles. Timothy succeeded St. Paul, and St. John is said to have had charge of the Church after Timothy, and to have died at Ephesus. It was long famous for its temple of Artemis (Diana), called Artemision, reckoned one of the seven wonders of the world. The temple was of the Ionic order, and was adorned with many pillars, each 60 feet high, and with numerous statues and paintings by the most celebrated Grecian masters. It had been destroyed seven or eight times before Pliny wrote, particularly by the notorious Herostratus, 356 B.C. The temple, however, was rebuilt by the Ephesians with more magnificence than ever, whose women contributed their trinkets to the general fund raised for this purpose. There were also many other temples here, a theatre, a stadium or race-course, gymnasia, odeum, etc. The site of the temple had become lost when it was discovered by Mr. Wood in 1867–9. In his excavations he found that the building measured about 343 feet by 164, and stood on a raised platform measuring 418 feet by 239. Important excavations have since been carried out here, and the theatre, important buildings connected with the gymnasium, and a splendid semicircular marble portico round the east side of the harbor have thus been disclosed. The Great Mosque or Church of St. John, the cave of the Seven Sleepers, and other interesting objects are to be seen here. Consult: Wood, 'Discoveries in Ancient Ephesus.'

Ephesus, Council of, the third general council of the Roman Catholic Church, held at Ephesus 431, principally to oppose the heresy of Nestorius, patriarch of Constantinople. It was convoked by the Emperor Theodosius II. at the instance of Pope Celestine I. and many Catholic bishops. Cyril, bishop of Alexandria, presided on behalf of Pope Celestine I. The number of bishops in the Council was about 200. Nestorius, adopting the teaching of Theodorus of Mopsuetia, denied the Church's doctrine of the incarnation, and held that instead of the Word being made man, he (the Word) simply had his special abode in the man Jesus Christ; and that hence Mary the Virgin was not θεοτοκος, God-bearing, mother of God, but only χρσστοτοκος, mother of the Christ. The Council declared that Mary is θεοτοκος, *Deipara*, and that Jesus Christ is God and man. (See COMMUNIO IDIOMATUM.) Another Council was held at Ephesus — the "robber synod," as it is called — in 449 convoked by the same emperor to deal with questions of faith connected with the teachings of Theodorus and Nestorius. The presiding bishop, Dioscurus of Alexandria, backed by a rabble of monks, soldiers, and servants overawed the 135 bishops, compelling them to sign blank papers on which he wrote what decrees he pleased.

Eph'od, a species of vestment woven of gold, blue, purple, scarlet, and fine twined linen, worn by the Jewish high-priest. It consisted of two main pieces, one covering the back, the other the breast and upper part of the body, fastened together on the shoulders by shoulder straps. On each shoulder was an onyx stone set in gold, on which were engraved the names of six tribes according to their order. A girdle or band, of one piece with the ephod, fastened it to the body. Just above the girdle, in the middle of the ephod, and joined to it by little gold chains, rested the square breastplate with the Urim and Thummim. The ephod was originally intended to be worn by the high-priest exclusively, but a similar vestment made of linen was worn in later times by priests of lower rank.

Ephors, ĕf'ôrs, or **Ephori,** magistrates common to many ancient Greek communities. The most celebrated were the Ephori of Sparta. They were five in number, and were elected by the people annually, their authority being designed as a counterpoise to that of the king and council. They superintended the morals and domestic economy of the community; scrutinized the conduct of all officials, and even summoned the kings before their tribunal. The judicial authority and executive power eventually fell almost entirely into their hands; they became autocratic; opposed the extension of popular privileges; and arousing the antagonism of the kings and people, were suppressed temporarily by Agis IV., and by Cleomenes III., the latter murdering the Ephors 225 B.C.

Ephorus, Greek historian, flourishing in the 4th century B.C., from about 400 to 330 B.C.; was born at Cyme, in Aeblis, Asia Minor. His master, Isocrates, after training him in rhetoric, persuaded him to abandon oratory for history, and it was upon his suggestion that he prepared his universal history. This work 'Ἱστορίαι', in 30 volumes, was the first history ever written in Greece and was remarkable for its wealth of material and also for the fact that each book, containing a compact portion of the history with an introduction, was complete in itself. The history deals with the Greeks (outside of the mythical age) from the return of the Heracleidæ to the siege of Perinthus (340 B.C.), covering a period of over 700 years. His style of writing was loose and feeble, well meriting the remark of Isocrates, that he needed the spur, as Theopompus the bit. The history was used and praised, however, by Polybius, Diodorus, and Strabo. The main portions of the manuscripts have perished, only a few fragments remaining, which were published in Muller's 'Fragments Historicorum Græcorum,' Vol. I., pp. 234–277 (Paris 1868).

Ephraem Syrus, ē'fra-ĕm sī'rŭs, **Ephrem,** or **Ephram** (the Syrian), Syrian theologian: b. Nisibis, Mesopotamia; d. Edessa 378. He lived in Nisibis till 363, but thereafter in Edessa till he died, except intervals which he spent in prayer and meditation in the desert. He held humble rank in the hierarchy, that of deacon, but as a preacher attained high celebrity. He refused to be ordained a priest because he thought himself unworthy. His writings were very numerous, and many are extant. He used a poetic form in his homilies and harangues; and St. Jerome tells us that his homilies (translated into Greek, for he wrote in Syriac) were wont to be read in many of the churches of Greece immediately after the Scripture lesson. He was a valiant defender of Catholic orthodoxy against the heretics of his time — Bardesanes, the Gnostic, the Arians, and the Sabellians, the Manichæans and the Novatians. Some of his lyrics are remarkable for their simplicity and genuine poetic spirit. Even his homilies are of a poetic cast and form; and in the translation of some of them they are styled «rhythms.»

Ephraim, the younger son of Joseph, and the founder of one of the 12 tribes of Israel. The tribe occupied one of the finest and most fruitful territories of Palestine; in the very centre of the land, and included the most of what was afterward called Samaria. It was bounded on the east by the River Jordan, on the west by the Mediterranean Sea and the tribe of Dan, on the south by the tribe of Benjamin, and on the north by that of Manasseh. The Ephraimites, when they left Egypt, numbered 40,500, and, being numerous and influential, often appear as the representatives of the 10 tribes, both in historical and prophetical passages of the scriptures. For a long time the ark and the tabernacle were situated at Shiloh. The tribe was the most warlike of all the Israelites as attested by their protests against Gideon (Judges viii. 1) and against Jephthah (Judges xii. 1–7) because they did not ask their aid in war. Joshua, who conquered the Holy Land, and Samuel, the prophet, were members of the tribe. Upon the death of Saul, the Ephraimites, in conjunction with all the other tribes except Judah, took part in the revolt of Saul's son Eshbaal (Ishbosheth), and recognized him as legitimate king in opposition to David (2 Sam. ii. 8–9), but upon his murder, submitted to the hegemony of Judah under David. Later, about 975 B.C., after the death of Solomon, the tribe revolted under Jeroboam against Rehoboam, the son of Solomon (1 Kings xii. 1–20), and with all the tribes except Judah, Simeon, part of Benjamin, and the Levites, merged into the northern kingdom of which they constituted the most important part. The separate kingdom still adhered to the name of Israel and made Shechem its capital. In 722 B.C. the kingdom was destroyed by the Assyrians.

Eph'rata, Pa., township and borough in Lancaster County; on the Reading & C. R.R.; about 50 miles northwest of Philadelphia. It is an agricultural and mining region with forests nearby. Ephrata was founded by Johann Conrad Beissel (q.v.) and his followers in 1735. The community established by Beissel was called «Order of the Solitary,» and it resembled somewhat the Seventh-Day Adventists. Ephrata contains several very ancient and singular buildings, particularly the brother and sister house. These houses are large four-story structures, each contains a chapel, and is divided into small apartments, so that six dormitories, barely large enough to contain a cot, a closet, and hour glass, surround a common room, in which each mess have their meals. The dress of the brethren and sisters is that of the Franciscans, or White Friars. They are remarkable for their rigid adherence to the precepts and ordinances of the New Testament; they insist upon the washing of the feet before administering the sacrament; and are very observant of the Sabbath. They are peaceful and temperate and are distinguished for their music, which is composed and arranged by themselves. Prior to the Revolution they seemed to flourish, but now only a few of the order remain in Ephrata. Pop. 2,400. Consult: Kuhns, 'German and Swiss Settlements of Colonial Pennsylvania'; Sachse, 'The German Sectarians of Pennsylvania,' 2 volumes.

Ep'iblast, one of the layers in the developing embryo from which the structures making up the skin and its appendages are developed; also called ectoderm. See EMBRYOLOGY.

Epic, from the Greek ἔπος, speech, ἐπικός a discourse, a poem of the narrative kind. This is all that the word properly signifies, although it is generally understood to be a poem of an elevated character, describing the exploits of heroes, as distinguished from the lyric representing emotion, and the dramatic representing action, these three classes comprising the different styles of poetical composition. As action is the object of the drama, so narration is that of the epic. But as the event related is something already past, the epic is less stirring, hence its more quiet tone, the pauses which may be allowed in the interest of the description, and the introduction of passages of philosophical reflections. Unity, however, governs the whole structure of the poem. The epic in a general sense is applied to all poems of a narrative character which illustrate the history of important mythological, religious, and national events, a distinction being made between epics of growth, which consist of collections of ballads or poems composed by different authors at different times, and dealing with a connected series of events, and art epics, in which the events are grouped around some great structural thought by a single poet. To the first class belong the Sanskrit 'Ramayana' and 'Mahábhárata,' the Finnish 'Kalevala,' the German 'Nibelungenlied,' and the mediæval French 'Chanson de Ron' or 'Roland.' In the second class are the 'Odyssey,' the 'Æneid,' 'Paradise lost,' and 'Gerusalemme Liberata.' Such epics as the 'Iliad' and the Persian 'Shah Nameh' again belong to both classes. The term heroic epic or heroic poem is applied to such works as Homer's 'Iliad' and 'Odyssey,' Virgil's 'Æneid,' Spenser's 'Faerie Queene,' Ercilla's 'Araucana,' Aristo's 'Orlando Furioso,' and others, which describe the achievements of the gods and heroes of antiquity, or of the knights of mediæval chivalry. Poems again like Milton's 'Paradise Lost,' Tasso's 'Gerusalemme Liberata,' Dante's 'Divina Commedia,' and Klopstock's 'Messiade,' are sacred epics. Lucan's 'Pharsalia,' Camoen's 'Lusiad,' and Voltaire's 'Henriade' are historical epics. Goethe's 'Herman and Dorothea' may be described as a domestic epic. Such poems as Scott's 'Marmion,' Longfellow's 'Evangeline' and 'Hiawatha,' are genuine miniature epics, while Tennyson's 'Idylls of the King,' from its artistic consecutiveness of motive, belongs also to the family. Of the mock-epic order are such poems as Pope's 'Rape of the Lock,' Butler's 'Hudibras,' and Boileau's comic epic 'Lutrin.' Epics also may utilize prose as a vehicle of thought and while less regular in form than the pure epic, may nevertheless be quite distinct from the common novel, or ordinary fiction; the best examples of prose epics are to be found in the Franch language, as such are: Fénelon's 'Télémaque,' Marmontel's 'Incas,' and St. Pierre's 'Paul et Virginie.' Consult Lang, 'Homer and the Epic' (1893).

Epicardium. See HEART.

Epichar'mus, Greek philosopher and comic poet: b. Cos about 540 B.C.; d. 450 B.C. He lived at Syracuse, and there wrote his celebrated comedies, now lost. Their number is reckoned at 52, and the titles of 40 of them have been preserved. Before commencing his career as a comic poet, which he did somewhat late in life, he lived at Megara, engaged in the study of philosophy, both physical and metaphysical. The fragments of his poems which are preserved abound with philosophical maxims, and with speculative discourses. His genius was highly esteemed among the ancients by such judges as Plato and Cicero. The Sicilian comedy of Epicharmus, prior to the Attic, grew out of the mimes, which were peculiar to this island, making a sort of popular poetry. He arranged the separate unconnected scenes, exhibited in the mimes, into continued plots, as in tragedy. His comedies were long regarded as models in this species of composition, and were as much distinguished by their knowledge of human nature as by their wit and lively dialogue. The Sicilian comedy, in opposition to the Attic-Ionic, is also designated as the Doric comedy.

Epicte'tus, Stoic philosopher: b. Hierapolis, Phrygia, about 60 A.D. He lived at Rome, where he was the slave of Epaphroditus, a brutal freedman of Nero, whose abuse and mal-treatment he bore with fortitude. Epictetus himself did not leave any written account of his doctrines, which appear to have been of the most elevated kind. In his discourses he aimed to impress his hearers with the love of practical goodness. The foundation of philosophy he held to be the perception of one's own weakness and inability to do what is needful. His doctrines approach more nearly to Christianity than those of any of the earlier Stoics, and although there is no trace in what is recorded of them of his having been directly acquainted with Christianity, it is at least probable that the ideas diffused by Christian teachers may have indirectly influenced them. The excellence of his system was universally acknowledged. Banished from Rome by Domitian, Epictetus settled in Epirus, and although he possessed the favor of Hadrian, there is no evidence that he returned to Rome. His pupil Arrian, the historian of Alexander the Great, collected his maxims with affectionate care, in the work entitled, 'Enchiridion' ('Handbook') and in eight books of 'Commentaries,' four of which are lost. These reveal the simple and noble earnestness of the philosopher's character, as well as that real heartfelt love of good and hatred of evil which is often assumed to be an exclusively Christian feeling.

Epicureanism. Epicureanism as a philosophical doctrine has its rise in the teachings of its founder Epicurus, who was born in Samos in the year 342 or 341 B.C. He was the son of Neocles and Chærestrata. His father's name being the same as that of the great statesman Themistocles, suggested to the poet Menander a verse in which he contrasts the son of Neocles, who freed his country from slavery, with him who freed it from foolishness. In his early life, Epicurus taught in several schools in Asia Minor and in the year 306 came to Athens, where he founded a school of his own. By the subtle charm of his personality he attracted to himself a group of admiring friends and followers who were not only devoted to the teacher but were also fired with enthusiastic zeal for his teaching. They were his companions and friends rather than his pupils. Their meeting place was the famous garden of the master which has become so closely associated with the very name of the school. After the death of Epicurus in 270 his followers carried on his work and maintained the teachings and traditions of their leader with unabated earnestness and loyalty. Among the successors of Epicurus, the most conspicuous perhaps are Hermarchus, Dionysius, Apollodorus, Zeno, and Phædrus. But no one of his followers achieved marked distinction until we come to the time of T. Lucretius Carus, the interpreter and chief apostle of Epicureanism. Though a Roman, he had caught that Greek spirit which had been so brilliantly illustrated in the garden of Athens.

Epicureanism as a distinct school flourished with varying fortunes until a period as late as the 4th century A.D. With the decay and disappearance of the school, its influences however did not cease, but lived on, and will live; for Epicureanism represents an attitude of mind which will ever appeal most strongly to certain natures, and in a way to all natures. It is not in a strict sense of the phrase, a system of philosophy. It is rather a theory of life. It is essentially practical in its purposes, methods and results. So far, however, as Epicureanism may be called a system of philosophy, it falls into three parts — a system of canonics, of nature and of morality. By canonics is meant a system which exhibits certain canons or tests of truth. With Epicurus the supreme test of truth was to be found in the sensations. It is the same thought as that which is contained in the old adage — seeing is believing. He held that only the actual facts of a sensory experience can furnish a scientific basis upon which to construct a body of knowledge. The notions are to be regarded merely as generalized sensations, and all opinions are inferences which at the last analysis must rest upon simple sensations. The sensation as such, therefore, is the court of last appeal. Concerning his philosophy of nature, Epicurus taught that there were only natural causes. Any belief in supernaturalism he regarded as a superstition which only a weak intellect could possibly entertain. As regards the constitution of matter, he followed Democritus in the essential features of his atomic theory of the universe. He did not follow, however, with complete rigor the logic of his materialistic conceptions, for he allowed that there must be a distinction between the irrational, or more sensory part of the soul on the one hand, and on the other, the rational part which he regarded as the superior and controlling power of man's nature. Moreover, while denying the existence of the gods, as gods of providence sustaining the forces of nature, and ruling the destinies of man, he nevertheless believed in their existence as beings apart and wholly separate from mundane affairs. From the standpoint of his ethical system, the gods were of very necessity beings supremely happy, and such they could not be were they supposed to be in any way cognizant of the darker side of nature and the manifold ills of human life. According to Epicurus the great end to be attained through the study of nature was to disabuse the mind of any lurking superstition concerning the possibility of the supernatural.

It is, however, the ethical system of Epicurus which is the heart of his teaching, and it is this system that the term Epicureanism usually suggests to one's mind. With Epicurus man's chief end is the attainment of pleasure,— not in the sense, however, that life is a heedless pursuit of pleasure here, there, and everywhere. The end is pleasure, not pleasures. The supreme pleasure, the constant source of all other pleasures is the tranquil and happy mind. In placing the true source of pleasure within, Epicurus here differs from the earlier Cyrenaic who regarded man's happiness as consisting in the full round of delights, the sum total of all his actual enjoyments. Epicurus taught that mere bodily pleasures were not an end in themselves, but only as they minister to peace of mind. Violent excesses disturb, extreme asceticism torments the inner spirit of man. Therefore be not too indulgent, nor too rigorous with self. Study to attain the maximum of enjoyment with the minimum of distress. Let a wise prudence transmute both the good and the evil of life into a tranquillity of soul. In this conception of conduct, virtue is never an end in itself. It is always a means to an end. The end is happiness and so far as a life of virtue contributes to well being, so far only is it to be commended.

We find in Epicureanism and in Stoicism alike, the common endeavor to free man from the dominion of circumstance, and to establish an inner world of mind wholly independent of the outer world of chance events, of untoward influences, of hostile forces and fleeting delights. The Stoic, however, urged the repression of all desire; the Epicurean, on the other hand, urged its wise regulation. As Epicurus himself puts it, "It is not an unbroken succession of drinking feasts and of revelry, not the pleasures of sexual love, nor the enjoyment of the fish and other delicacies of a splendid table, which produce a pleasant life, it is sober reasoning, searching out the reasons for every choice and avoidance, and banishing those beliefs through which greatest tumults take possession of the soul. Of all this, the beginning and the greatest good is prudence. Wherefore prudence is a more precious thing even than philosophy: from it grow all the other virtues,— for, it teaches that we cannot lead a life of pleasure which is not also a life of prudence, honor and justice, nor lead a life of prudence, honor and justice which is not also a life of pleasure. For the virtues have grown into one with a pleasant life, and a pleasant life is inseparable from them." JOHN GRIER HIBBEN,

Professor of Philosophy, Princeton University.

Epicurus, ĕp-ĭ-kū'rŭs, Greek philosopher: b. Samos, 342 B.C.; d. Athens 270 B.C. He went to Athens 323 B.C., where he is said to have enjoyed the instructions of Xenocrates, then at the head of the Academy, but this he himself does not admit. Epicurus generally denied his obligations to other philosophers. Although some parts of his system are evidently borrowed from his predecessors, he claimed to be self-instructed, and treated his teachers with hostility and contempt. His stay at Athens, however, was brief; and on leaving it he went to Colophon, where his father was engaged in teaching, and began himself to give lessons in grammar. It was here, according to some accounts, that his attention was first turned to philosophy. He himself says he began his philosophical studies at the age of 14, but they may have subsequently taken a more distinct development. The inability of the grammarians to explain a passage about Chaos and the accidental possession of a copy of the works of Democritus are variously assigned as the cause of this new or more decided direction of his mind. From Colophon he went to

Mytilene and Lampsacus, where he engaged in teaching philosophy. He returned to Athens in 306, and purchased a garden in a favorable situation, where he established a philosophical school. Here he spent the remainder of his life. His mode of life appears to have been simple and temperate. He abstained, as a principle, from politics, and took no part in public affairs. During the latter part of his life he was afflicted with severe physical suffering which was borne with heroic courage.

Epicurus was a very voluminous writer. His works, however, are represented as full of repetitions and quotations. In ancient times his philosophy appears to have been more popular in Greece than in Rome, although his disciples were numerous in both. This is easily comprehended, as it was in fact a system engendered by the decline of public virtue in Greece, while the severest stoical philosophy was better adapted to the still active public spirit of Rome. Little is left of his numerous writings. Some fragments of a 'Treatise on Nature' were found at Herculaneum, and published by Orelli (1818). All other fragments have been published by Usener in his 'Epicurea' (1887). The chief account of his philosophy is contained in the great poem of Lucretius, 'De Rerum Natura,' one of the masterpieces of Roman literature.

Ep'icycle, in ancient astronomy, a small circle supposed to move round the circumference of a larger, a hypothetical mode of representing the apparent motion of the planets, which were supposed to have such a motion round the circumference of a large circle, called the deferent, having the earth in its centre. In modern times, the epicycle is used in order to express in a few words the numerical value of periodical functions of an unknown law. Thus if the fluctuations of the thermometer for a day be observed, the size and initial position of several circles may be calculated, such that if the centre of the 2d move uniformly round the 1st once in 24 hours, the 3d round the 2d once in 12 hours, the 4th round the 3d once in 8 hours, etc., the height of the centre of the 4th or 5th circle will be the same as that of the mercury. See ASTRONOMY.

Epicy'cloid, in geometry, is a curve generated by a point in one circle, which rolls on the circumference of another circle, either on the concavity or the convexity, and it thus differs from the common cycloid, which is generated by a point in a circle that rolls along a right line. The latter has sometimes been assimilated with the former, by considering the right line as the circumference of a circle whose diameter is infinite. The invention of epicycloids is ascribed to M. Roemer, the Danish astronomer. See GEOMETRY.

Epicy'cloidal Wheel, a wheel or ring fixed to a framework, toothed on its inner side, and having in gear with it another toothed wheel of half the diameter of the first, fitted so as to revolve about the centre of the latter. It is used for converting circular into alternate motion, or alternate into circular.

Epidaurus, ĕp ĭ dâ'rŭs, one of the most important towns and commercial seaports of ancient Greece, situated in Argolis, in the Peloponnesus, particularly celebrated for its magnificent temple of Æsculapius, which stood on an eminence not far from the town. An inscription over the entrance declared it to be open only to pure souls. Crowds of invalids resorted to the place in hopes of obtaining a cure from the beneficent divinity, in whose honor festivals were celebrated yearly. It received its name from Epidaurus, a son of Argus and Evadne. It is now called Pidavro, or Edidairo, and is the place where in 1821 the first Greek Congress assembled. The modern town contains about 100 inhabitants. Consult: Diehl, 'Excursions in Greece' (1893).

Epidemiology, ĕp-ĭ-dē-mĭ-ŏl'ō-jĭ, the study of epidemics or the science that treats of those diseases that are known to attack a number of persons at the same time or in close succession. The essential feature is that epidemic diseases belong to a group of infective or microparasitic maladies which have the common property of spreading from time to time in a community. It is well known that many diseases of an epidemic character have their favorite haunts. In such places they are always present, and there they are said to be endemic. It is only when they appear in large numbers of people in their favorite habitats that they assume epidemic proportions. Thus there is little distinction between the two classes of disease, since the same disease may be at one time both endemic and epidemic. When an epidemic disease, for instance, influenza, spreads the entire world over, the word pandemic is applied. The essential feature in an epidemic disease is that it must have a definite contagium. The contagia may be either of bacterial or protozoan character. Thus cholera, dysentery, the plague are caused, as is known, by bacteria which, being carried in the ordinary paths of commerce, or by bodies of a moving population, are spread about the world. Occasionally epidemic disease is due to an animal parasite. This is presumed to be the case in yellow fever, and is known to be true of malaria. In malaria, as is now positively demonstrated, the agent that is all-important in the spreading of the disease is one genus of mosquito, *Anopheles*. The parasite lives normally in the human body, and is conveyed by means of the blood into the mosquito, where it undergoes a special cycle of development, until it is inoculated into another human being, who develops the disease.

Further, it may be said that the essential features for the development of epidemic conditions are: (1) A virus; (2) a susceptible population; (3) free intercommunication between the sick and the susceptible. In the group in which the animal parasites belong there must be: (1) A virus; (2) a breeding-place outside of man; (3) a means of transport from place to place, either naturally or artificially; (4) a vehicle for the diffusion of the disease, such as the mosquito, for instance, or a contaminated water-supply, or a person suffering from the disease who travels from place to place, and (5) a susceptible population. It is well known that variation in the susceptibility of populations is a very important element in the consideration of epidemics. Thus measles, whooping-cough, diphtheria, and similar affections ravaged Hawaiian (formerly Sandwich) Islands with a fierceness and mortality unknown to modern times. Seasonal movements, sectional fluctuations, time fluctuations, and oscillations are interesting features in the study of epidemics. By some writers the word epidemic is very loosely used to indicate certain waves of mental excitation which have caused and still cause mental storms throughout a community, as the dancing mania and similar occurrences. These cannot be spoken of as epidemics in the true sense unless one wishes to use the broad term of "emotional contagion." Some of the most interesting epidemics of modern years have been the influenza epidemic of 1890, which traveled round the world in from three to four years, and the plague epidemic that was raging from 1895 to 1902, slowly traveling over the habitable globe. There have been no severe extensive epidemics in the United States, save the epidemic of influenza, for a great many years, and in civilized countries at the present time the chances for the spreading of more severe epidemics are greatly lessened by the application of the laws of modern hygiene as well as by procedures arising from the newly acquired knowledge concerning immunity. The time does not seem far distant when immunity to many forms of infectious disease may be conferred by proper serum therapy. Consult: Hirsch, 'The Geographical Distribution of Disease' (1893); Weichselbaum, 'Epidemiologie' (1900); and 'Epidemiology' in 'Encyclopedia Medica' (1900).

Epiden'drum, a large genus of tropical American orchids, most of the species of which are epiphytic, growing on trees. There are upward of 600 species in South America alone. The stems are pseudo-bulbs, the leaves are strap-shaped and leathery, and the flowers are single or in spikes, panicles, or racemes. The flowers of some species are very handsome, and a large number of the species are in cultivation. Two of the finest cultivated species are the Mexican plants *E. nemorale* and *E. vitellinum*, the former with rose-colored and the latter with orange-colored flowers. The plants are much used in hybridization, as they are hardy and rigorous, and are valuable for crossing with the less hardy species of other genera, the result being in many cases long-stemmed flowers of fine appearance.

Epider'mis. See SKIN.

Epidid'ymis. See TESTICLE.

Epididymi'tis, inflammation of the epididymis, resulting in pain, redness, heat, and swelling of the testicle, with general constitutional malaise. Treatment consists in rest in bed and soothing applications.

Ep'idote, a common mineral, usually yellowish-green in color, and crystallizing in prismatic forms belonging to the monoclinic system. It is a silicate of calcium, iron, and aluminum, with the general formula $HCa_2(Al, Fe)_3Si_3O_{13}$, the ratio of the aluminum to the iron varying, in different specimens, from 6:1 to 3:2. Its hardness is from 6 to 7, and its specific gravity is about 3.4. Epidote occurs throughout the world. Fine crystals are found in France; the Tyrol: Haddam, Conn.; Calumet, Colorado; and Alaska. The epidote group contains, in addition to epidote proper, the minerals piedmontite and allanite, which resemble it in general nature but contain manganese and cerium respectively; and also the calcium epidote, zoisite, which crystallizes in the orthorhombic system.

Epigæa, ĕp-ĭ-jē'a. See ARBUTUS, TRAILING.

Epigas'trium, the upper fore part of the abdomen, reaching from the pit of the stomach to an imaginary line above the umbilicus (navel) supposed to be drawn from the one extremity of the last false rib, on one side, to the corresponding point on the other.

Epigene, ĕp'ĭ-jĕn, a term applied to those geological agents of change which affect chiefly the superficial portions of the earth's crust, as the atmosphere, water, plants, and animals.

Epigenesis, ĕp-ĭ-jĕn'ĕ-sĭs, in biology, the development of the animal from the simple protoplasm of the egg. This term therefore expresses the theory and process of embryology as now understood, and is opposed to the prevailing theory, previous to the researches of Harvey, and especially of Wolff and Von Baer, which was then known as the *emboitment* theory, an account of which is given under PREFORMATION. See also EMBRYOLOGY.

In physiology the supposed production in organized beings of or additional formations by means of new vital influences, as opposed to the idea that new parts are simply the result of developments or changes in pre-existing structures.

Epiglot'tis, the cartilage at the root of the tongue forming a valve which partly closes the aperture of the larynx during the process of swallowing. When respiration takes place the epiglottis is vertical but falls back and covers the larynx on the approach of food. Any portion of food, however minute, entering the sensitive larynx, causes distress and is automatically ejected by a spasm of coughing.

Epigoni, a name given in Greek legend to the sons of the seven Greek chiefs who conducted the expedition against Thebes in the war between Eteocles and Polynices. The name literally means descendents, successors, or heirs, and the second expedition in command of the sons to avenge the first disastrous defeat was thus called the "war of the epigoni." The name is also applied to students who attempt to develop the ideas of the great masters of a previous period.

Epigram. The Greek noun from which the word epigram comes was originally used to denote a prose inscription on a temple, tomb, statue, votive-offering to a god, or the like. Conciseness and brevity were, therefore, essential qualities. To give pleasure to the ear and help the memory, the Greeks next chose some poetic form for them, preferably the elegiac distich. Their use for practical purposes eventually suggested their composition as a form of literature, with subject-matter sometimes wholly imaginary. These poems now often embraced several distichs, and appeared in other metres, but continued to be ordinarily of a simple, expository or descriptive nature. In the Alexandrine period, however, when poets affected almost exclusively short but highly elaborate poems, epigram lost much in simplicity while attaining its highest popularity among the Greeks. Its composition had become the pastime, and even the serious ambition of authors of first rank, and its recitation and improvisation one of the favorite entertainments at symposia and other social gatherings. Collections of epigraphical epigrams were made. Meleager of Gadara followed these early in the first century B.C. with his "Garland" of literary epigrams, the prototype of our Greek Anthology or "Bouquet of Flowers." This numbers about 4,500 poems by over 300 writers in two collections, the Palatine Anthology of Constantinus Cephalas (early 10th A.D.), and that which Planudes made four centuries later, supplying important additions. These collections with countless poetical inscriptions found in modern times constitute for us Greek epigrammatic literature. The Greek Anthology not only throws valuable light on human life from the time of the Persian wars to the age of the Byzantine collectors, but through widespread translation and imitation has deeply affected modern languages and thought. For the names of the prominent writers and a characterization of their work see the special article "Anthology." As a literary genre imported from the Greeks, epigram enters Latin literature with Ennius, but as an inscriptional poem much earlier. Latin is peculiarly adapted to a lapidary, epigrammatic style, and certain racial characteristics, in particular their devotion to the practical, made the Romans naturalize this species of poetry at once. At first they modeled after the Greeks, and we have a few specimens of the erotic epigram as the Alexandrines wrote it. By Cicero's time most of the literary men of importance were writing epigram, and its value as a political weapon was fully appreciated. Catullus is, however, the only writer from whom we have any considerable collection. Although we find in him lyric qualities as fine as in the poems of the Anthology, it is still clear that the national aptitude for satire has already turned epigram strongly in that direction. It is the Latin satiric epigram and not the more lyrical Greek that becomes the model for modern writers. In the Augustan Age, Domitius Marsus and Pedo Albinovanus were, according to Martial, the greatest epigrammatists, but we have not enough of their work to judge it. Martial himself brought this branch of poetry to its acme. None of the eminent poets who followed in his steps, Petronius, Apuleius, Ausonius, and Claudian, have equalled him in epigram. In the sixth century Luxorius maintains the tradition, but at a low level. About this time the Salmasian collection was made which forms the nucleus of the modern compilations which we call the Latin Anthology. In the time of Charlemagne epigram enjoyed a veritable renaissance, taking the inscriptional form to describe the material glories of Christianity as well as to sing the praises of the dignitaries of the church. Then the humanists, to whom Latin was almost a second mother tongue, revived this form once more. But the Latin scholars who have written epigrams are too numerous to name here. One, John Owen of Oxford, should not perhaps be passed by, since he devoted himself wholly to this field and with marked success. In English literature the composition of epigram has long been out of fashion, but for centuries it was popular with literary men. Notable achievements in this line are to be found in the works of Herrick, Johnson, Dryden, Swift, Prior, Addison, Johnson, Goldsmith, Congreve, Hood, Hook, Byron, and Burns. Pope's poems might be reckoned a conglomeration of epigrams. Some of the best in our language are by Landor, who cutting loose from the Latin type, at times becomes a Greek in spirit. Epigram has enjoyed wide favor in other modern tongues. In Italy, it long played an important part in politics, as both the Pasquino and Marforio in Rome would testify, could they speak, but it has gradually given way to the madrigal and sonnet. In France from the time of Clément Marot, who introduced it from the Latin, the satiric sort has enjoyed a wonderful popularity. Boileau, J. B. Rousseau, Piron, Lebrun, and Chénier have shown its possibilities in many lines. The poetic Priamel of the 14th century may be said to begin epigrammatic literature in Germany, where indeed it has always inclined more to the moral and didactic than in the Latin countries. Among her more eminent epigrammatists are Opitz, Friedrich von Logau who is the best of all, Wernicke, Kästner, Klopstock, Lessing, Herder, Schiller, and Goethe, who brought out their "Xenien" together in 1797, Haug, and in more recent times Bodenstedt, Vischer, and Fulda. We pass from the history to the theory of epigram. Since it is unlimited in its choice of subject, the form and not the contents must determine whether a poem is an epigram or not. Lessing has shown much acumen in tracing the essential elements of the epigram in its modern conception to the primitive type, the inscription. Just as a monument arouses in a spectator a curiosity about the author and purpose of its construction, which the inscription then satisfies, so the first part of a literary epigram, whether dealing with some material object, or not, is intended to excite an interest which the close of the poem must duly satisfy. The suspense may be increased by making the prefatory portion of some length. The more remotely separated and apparently contradictory the ideas that are brought together, and the briefer and more unexpected the commentary or explanation at the end, the more successful we deem the poem. This point or conclusion becomes in the satiric epigram a sting. Hence the frequent comparison of an epigram to a bee or wasp. While the above applies to most epigrams as written to-day, no definition is quite satisfactory with reference to much that the ancients included under the term.

Walton Brooks McDaniel,
Assistant Professor of Classical Philology, University of Pennsylvania.

Ep'ilepsy, a disease of the nervous system, c..racterized for the most part by a sudden brief disturbance of the brain functions, and usually attended with a loss or a diminution of consciousness, with some degree of convulsive muscular action. In the vast majority of cases the temporary loss of consciousness permits of the loss of muscular control, and the patient falls; hence the old name, the "falling-evil," or "falling-sickness." Epilepsy is a disease which was recognized in its pure type by the most ancient observers. Hippocrates described it, and evidences are found in the earliest Indian writings of Charaka that the disease was then known. The present belief is that the primary disturbance of function which induces the epileptic attack takes place in the cortex of the brain, usually involving the motor centres; but this is not essential, since it may spread from other centres to the motor region, or the disturbance may be confined entirely to other portions of the brain, resulting in anomalous epileptic seizures.

A single convulsion does not constitute an epileptic attack, nor do a few convulsions. Convulsions of reflex origin are extremely common in childhood and infancy, and get well on the removal of an irritant, such as impacted fæces or a tight prepuce, or muscular defects in the eye-apparatus. These are not epilepsies. One of the distinguishing features of epilepsy is the tendency to a recurrence of the attacks. Gowers says: "As a disease, it consists in the repetition of attacks which depend upon the fact that every functional state of the brain, normal or abnormal, leaves behind it a condition in which the same functional state occurs with greater readiness. The effect is the greater the more often the functional attack has occurred. The tendency to the recurrence of attacks of epilepsy of every form is increased by each one. Every fit, slight or severe, is in some degree the effect of those that have preceded it, the cause of those that follow it. This residual disposition of repetition of the same activity is the physical basis of memory, of muscular training, of all cerebral education, and it is the basis of the morbid education of the brain which underlies epilepsy. The recognition of this is essential for an adequate comprehension of the causation of epilepsy and also its successful treatment." Further, as Gowers observes, "If we can perceive the conditions that underlie normal action in the nerve-centres, the phenomena of epilepsy will become in some degree less mysterious. In health, energy is liberated in instant response to a definite stimulus. Such capacity for instant activity involves a delicate equipoise of the processes for the liberation of nerve-force and for its restraint or control. The balance must depend upon the processes of nutrition in the nerve-structures, for the liberation of energy depends upon the occurrence of chemical processes under the influence of life — processes which must be ever on the verge of disturbance. But the conditions of nutrition must involve constant tranquil molecular changes, and, as a consequence, some degree of equally tranquil functional activity. The store of latent energy must be maintained by nutritional processes, which involve a constant overflow of energy, as from a vessel filled to the brim and delicately poised, into which water is gently flowing, but the equilibrium of which is easily disturbed, with a resulting energetic discharge."

The symptoms of epilepsy in all its forms are too numerous to be treated outside of medical works. Suffice it to say, in general, that the kinds of epileptic attacks are, for purposes of convenience, divided into two classes — the severe form, to which the term *grand mal* has been applied, and in which there is loss of consciousness often prolonged, with severe muscular spasms; and the slight attacks or *petit mal*, in which there may be slight temporary loss of consciousness with slight muscular spasm, or only slight muscular spasm without loss of consciousness, or slight disturbance in the conscious field without recognizable muscular movements. There are minor attacks, often called "faints," "turns," "queer feelings," etc., but they should not be mistaken for closely similar phenomena attendant on menstruation, indigestion, weak heart and circulation, etc.

In a typical *grand mal* attack, eschewing all refinements, the patient may have some sort of a warning of the oncoming storm. This is called the *aura*, and is usually present in from 30 to 40 per cent of all cases. This aura may be motor, sensorial, or intellectual. Thus the patient may feel a wave of hot air passing over the body; may have a sensation of griping at the throat; there may be a feeling of great buoyancy or exaltation. There may be abnormalities in taste, smell, sight, or some flashes of light, dark objects; partial blindness, roaring in the ears, noises in the head, bad taste in the mouth, indescribable sensations in the pit of the stomach — all these are types of the initial warning. Suddenly after this warning, or almost simultaneously with it the patient falls to the ground. Consecutively on this sudden fall severe tonic spasms of the muscles take place. Occasionally these spasms follow a definite order. Thus the fingers may be clutched, the arm raised backward and forward, one side of the body convulsed, this condition extending to the legs, the chest, the abdomen; and in *each succeeding attack the same order be followed*. When this occurs the disease is termed "Jacksonian" epilepsy, and this is one of the forms of the affection in which a localization of the cause can sometimes be made out. More usually, however, the attack is generalized. There are rigid, violent muscular contractions, which fix the limbs in irregular positions. It has been aptly described as a "clotted mass of movements." The head and eyes may be turned to one side, the features are distorted, the face becomes flushed and then pale and livid from fixation of the chest and the loss of movements of respiration. The eyes may be opened or closed, the pupils more or less dilated as the patient becomes more and more livid. After this tonic intense contraction has lasted for a few seconds, the backward clonic movements of the reaction occur, and the most violent energetic movements of the muscles of the entire body may take place. The jerking movements gradually become less, or terminate in one violent distortion, and the patient lies senseless and prostrate and usually sleeps for some time. During the attack the urine, fæces, or semen may be passed.

As for the minor attacks (*petit mal*), they exhibit an endless procession of variations. In some there may be but a slight loss of consciousness; the patient, sitting down or leaning against a table or chair, suddenly stops in the middle of his play or conversation; a shade passes over the face, and in a moment he is himself again. Occasionally the patient feels sleepy, lies down for a second, and then gets up perfectly well. Occasionally there is a slight convulsion, an involuntary contraction and extension of some of the muscles without loss of consciousness, and the patient resumes his regular course of work or play. Occasionally the patient suffers from what is known as psychical attacks, during which there is an entire modification in the personality; and during the attack various automatic movements may be performed and a patient be entirely unaware of what he is doing. These automatic movements may persist for some time, a few seconds, minutes, an hour, a day, a week, in certain cases as long as a month, although these longer intervals are extremely rare and perhaps are something different. During such automatic condition the patient may wander from home frequent resorts, the character of which is unknown to him in his waking state, and may even commit homicide or suicide. The patients usually show great irritability and restlessness during these automatic states. These states are extremely common following *grand mal.* There are patients with epilepsy who show no other signs of the epileptic attack than this automatic condition.

Etiology.— The causes of the disease are predisposing and exciting: those that exist in the family history, and those that occur during the life of the individual. A great many cases of epilepsy are due to accidents during childbirth, especially when the labor has been prolonged and difficult: sometimes when it has been precipitate; both resulting in hemorrhage into the meninges of the brain or into the brain substance proper. Perhaps 70 per cent of the cases of infantile epilepsy are due to this cause. A neuropathic tendency is almost a *sine qua non* for the development of idiopathic epilepsy. Almost 40 per cent of these cases are found to exist in families that show this neurotic, run-down character. Alcoholism in the parents is of immense importance. Syphilis and tuberculosis are also important features acting as predisposing causes. Females suffer more from epilepsy than males, the proportion being about 52 to 48 per cent. Gower's analysis of 3,000 cases, bearing on the question at what age this disease commences, shows that 27 per cent commenced below the age of 10; 46 per cent between the age of 10 and 20; 15 per cent between 20 and 30; 10 per cent between 30 and 40; 1 per cent between 50 and 60; and ½ per cent between 60 and 80.

The course of the disease will naturally vary very widely. Actual mortality from epilepsy is very difficult to determine. The danger to life during an attack is not great, and although the patients may seem to be in an alarming condition, it is extremely rare for death to occur during a fit. Gowers has summed up the prognosis in idiopathic epilepsy as follows: "The prognosis is slightly more favorable if the patient is of the female sex, and distinctly more favorable if the disease begins over 20 than if it commences between 10 and 20. It is better the shorter the duration of the disease, and when the disease is inherited than when no heredity can be traced. It is better the greater the interval between the severe fits, and is least so in the cases in which attacks occur almost daily. It is better if the attacks occur in the sleeping or the waking state only than if they occur in both. It is better if there is no considerable mental change, and if the attacks are all of the severe variety, than if there are minor seizures, and better if the attacks are preceded by an aura than if they occur without warning. It must be recognized, however, that a really good prognosis can seldom be given unless all attacks are averted by bromide in moderate doses, such as 50 or 60 grains a day. Larger doses may diminish the fits but seldom effect a cure, and this is true also of the substitute for bromide. Successful results are sometimes obtained, but they are few. The prognosis in cases which "cannot bear" bromide is generally unfavorable so far as the prospect of a cure is concerned. But in all cases the ultimate result largely depends on the ability to secure persistence with effective treatment for a sufficient time, two or three years. Less does not secure the stability that allows the controlling agent to be discontinued with impunity. It is the case whatever the agent is. Premature cessation of treatment is certain to involve recurrence, and the fresh start is harder than the first. There is no short road to a cure, and the prognosis must be largely influenced by the presence of the necessary patience and wisdom.

Occasionally patients, while in the epileptic condition, suffer mortal accidents; a few die of asphyxia. Some, especially those with mild epilepsy, get well of themselves; but those with severe epilepsy usually continue to have their attacks at varying intervals, from several a day to one a day, one a month, one a year, throughout their lifetime, and die of intercurrent troubles. The end, however, that can be looked for in a great many cases of epilepsy is the condition known as *status epilepticus.* It may be regarded as the terminal stage in epilepsy. It consists of repeated and continued epileptic attacks, associated with high fever and usually ending in death. Patients in the condition of *status* may have as many as 300 or 400 convulsive attacks a day.

The prognosis of the disease, or the outcome, is a subject that cannot be decided on general grounds. It is always a question of the individual; but epilepsy in general should be considered as a very grave disorder with a poor prognosis, although careful treatment by a specialist may result in great alleviation if not permanent cure. There is probably no disease of the nervous system that requires more highly specialized knowledge to treat than epilepsy.

The diagnosis is extremely difficult, and epilepsy is confounded with a number of other conditions that have no relationship whatever to it. The lack of ability to make a correct diagnosis, with the extreme mendacity of the charlatan, is the basis of the many quack remedies on the market for the treatment of epilepsy. In the United States there are no less than 1,000 sure cures manufactured by various proprietors of quack medicines, most of which are solutions of bromides. Suffice it to say that most of these are worthless, and the cures brought about, as evidenced in many of the circulars, have been cures of other diseases than epilepsy.

The treatment of epilepsy is always a special problem. There is no such thing as the treatment of the disease; it is always the treatment of the patient. No general rules can be laid down in an article of this kind apart from the general observance of hygienic laws. An outdoor life, with a mild, healthy occupation, plain, digestible food, the absence of alcohol, tobacco, and other stimulants, a free intestinal canal, and surroundings in consonance with the mental capacity of the patient, are very desirable features. Medicinal treatment lies solely in the province of the family physician or the specialist. During an attack the patient should have a pillow thrust under the head, the clothes about the neck loosened, and he should be placed in a position that will not permit of self-harm. Otherwise the epileptic fit is best left untreated. For the treatment of the epileptic poor, modern philanthropy has devised epileptic colonies (q.v.).

Medico-Legal Relations.— Very frequently epileptics are a menace to society. In the automatic conditions which they exhibit, as already described, they frequently commit crime, and it becomes a matter of much importance to determine their responsibility at the time of the perpetration of such anti-social acts. Special consideration should be given to the heredity of the patient, to the previous course of the disease, and to the conditions surrounding the patient at the time of the act. It is at the present time a very popular plea for murderers to allege that they were epileptic at the time of the commitment of certain acts. This is a plea that is entitled to careful weight on the part of an intelligent jury, although there is little doubt but that at the present time it is greatly abused. Consult: Gowers, 'Epilepsy and Other Chronic Convulsive Diseases' (2d ed. 1901); Féré, 'L'Epilepsie' (1899); Binswanger, 'Die Epilepsie' (1900); Voisin, 'L'Epilepsie' (1899); Letchworth, 'Care and Treatment of Epileptics' (1900); Starr, 'Text-book of Nervous Diseases' (1903).

Smith Ely Jelliffe, M.D.,
Editor Journal of Nervous and Mental Disease.

Epileptic Colonies. The treatment and care of epileptics in special institutions may be said to be one of the developments of applied philanthropy of distinctly recent origin. By the founding of epileptic colonies is meant the setting apart of distinct tracts of ground for buildings and for the exclusive care and training of epileptics. The position of the epileptic in society is altogether anomalous. As Letchworth well says: "As a child he is an object of solicitude to his parents and guardians. The streets to him are full of dangers, and if sent to school he is apt to have seizures on the way or in the class-room. His attacks shock his classmates and create confusion. He cannot attend church or public entertainments, nor participate in social gatherings with those of his own age and station. In consequence of his infirmity the epileptic grows up in idleness and ignorance, bereft of companionship outside of the family, and friendless. He silently broods over his isolated and helpless condition." The recognition of these truths has caused philanthropists to found such colonies. In continental countries more has been done for epileptics than elsewhere, but in the last 10 years the movement for taking care of this unfortunate class of society has grown to large proportions and, as expressed by Peterson in his presidential address to the National Association for the Treatment and Care of Epileptics 1902, "there is hardly a community in the civilized world that is not now thoroughly aroused to the necessity for the treatment of this class of defectives."

This awakening took place about 1887, and has continued to the present time. The first distinct attempt to provide for epileptics was inaugurated by a Lutheran pastor, Friedrich von Bodelschwingh, who founded at Bielefeld, in Westphalia, Germany, the Bethel Colony, which, from small beginnings, has grown up to a village inhabited solely by epileptics. Here everything has been provided to meet their special needs, to make up for their deprivations in the outside world. They are supplied with schools to improve their minds, industrial teachers to make them more or less self-supporting, and physicians to study and treat their cases. Outdoor occupations are provided, special diet is arranged for, recreations, amusements, religious instruction, in fact all of the devices that go to make up a home, have been provided under this man's guidance, so that in 1903 at least 4,000 people, not less than half of whom are epileptics, are being taken care of in Bethel.

The success of the Bielefeld Colony prompted movements elsewhere. Other colonies were founded in Germany and other European countries. Ohio established the first institution for epileptics in the United States, although this was built on the hospital rather than the colony plan. New York has Craig Colony at Sonyea, one of the most elaborate and beautiful institutions of this class, closely modeled on the Bielefeld plan, and now (1903) with a population of nearly 1,000. Massachusetts has a colony at Palmer; Pennsylvania a colony farm at Oakburn; and there is a New Jersey State village for epileptics at Skillman. A colony for epileptics was begun in 1902 at Abilene, Texas, and there are movements on foot for similar establishments in Connecticut, Indiana, Illinois, Kansas, North Carolina, Missouri, Minnesota, and California. In England the first colony founded was at Chalfont in 1893 and another at Warford in 1900. There is also a colony, the Waghull Home, near Liverpool; another at Godalming; a large colony at Chelford, and finally a fifth institution in England is nearing completion (1903) for the city of London, not far from Croydon. Other colonies have been founded in Brazil, Belgium, Switzerland, Sweden, Russia, Italy, Turkey, India, Japan and Australia.

The Craig Colony, of Sonyea, N. Y., being one of the most modern and ideal, is selected as a type of this institution. Consult: Letchworth, 'Care and Treatment of Epileptics' (1900).

Epileptic Insanity, a mental complex accompanying epilepsy. It is characterized by a certain degree of mental deterioration, as shown in the impairment of intellect and memory, by impulsiveness, mental irritability, loss of moral sense, and partial or complete loss of productiveness. It is also accompanied by periodic disturbances, transitory attacks of anger, dream-states, or automatic phenomena. Many cases of epilepsy do not develop into epileptic insanity, but the mental deterioration may appear at almost any period following the onset of the epilepsy. In practically all cases of epileptic insanity there is pronounced weakness, mentally, morally, and emotionally. One's sense of one's surroundings is usually preserved, and consciousnes may be clear save during the dream-states or automatic periods. Comprehension is usually not markedly impaired, but the field of attention is diminished and easily diverted. Hallucinations are infrequent, illusions are common during an attack or following a grand mal seizure, and delusions are transitory, being found usually only in the dream-states. Morbid and sudden impulses are quite frequent, sometimes approaching distinct nerve-storms, during which suicidal and homicidal attacks may occur. The conduct otherwise is usually orderly, and the ordinary rules of propriety are observed. There is greatly diminished capacity for work in practically all epileptics. The subject of epileptic insanity is one deserving wide recognition as there are unquestionably a number of phenomena termed "psychical" epilepsy that need recognition by specialists. In some of these attacks the patients are confused. They move in a mechanical or automatic manner. They wander aimlessly about, recognizing no one, although sometimes answering incoherently when addressed. Occasionally they exhibit symptoms of excitement, at other times depression, and not infrequently they may set fire to their beds or furniture, commit theft, assaults, homicides, expose their persons, and otherwise conduct themselves in an irrelevant and insane manner. Treatment is always unsatisfactory. The patient should be kept in a sanatorium or asylum. See EPILEPSY.

Epilo'bium, the willow-herbs, a genus of plants belonging to the evening primrose family (*Onagraceæ*). The species are herbs or under-shrubs with pink or purple, rarely yellow, flowers, single in the axils of the leaves, or having terminal leafy spikes. The seeds are tipped with a pencil of silky hairs, and are contained in a long four-celled capsule. There are about 65 species scattered over the arctic and temperate regions of the world, 40 of them being found in the western and northwestern portions of North America. *E. hirsutum*, or codlins-and-creams, a great hairy willow-herb, is a common and conspicuous plant of waste places in New England and northern New York. Its flowers are pink and rather large, and the whole plant is very downy. Some species are cultivated, but are more common in England cottage gardens than in America.

Ep'ilogue (from the Greek *epi*, upon, and *logos*, word, speech), the closing address to the audience at the end of a play. The epilogue is the opposite of the prologue, or opening address. Many of Shakespeare's plays have an epilogue as well as prologue, in which the poet sometimes craves the indulgence of the spectators for the faults of his piece and the performance, and sometimes intimates in what light his work is to be considered. The epilogue is sometimes a necessary appendage, to tell us something of a composition, which cannot be gathered from the composition itself.

Epimenides, ĕp-ĭ-mĕn'ĭ-dēz, Cretan philosopher and poet: b. Crete, in the 7th century B.C. By some he is reckoned among the seven wise men, instead of Periander. When the Athenians were visited with war and pestilence, and the oracle declared that they had drawn on themselves the divine anger by the profanation of the temple, in which the followers of Cylon had been put to death, and must expiate their offense, they sent for Epimenides, who was renowned for his wisdom and piety, from Crete, to purify the temple. On his departure he refused to accept any presents, and only asked the friendship of the Athenians on behalf of Cnossus, his home. There is a story of his having, when a boy, slept in a cavern for 57 years. On awakening, he found, to his astonishment, everything changed in his native town. This story is the ground-work of Goethe's poem, the 'Waking of Epimenides,' for the anniversary of the battle of Leipsic. According to some accounts he is said to have lived for upward of 150, according to others for nearly 300, years. He is supposed to be the prophet referred to by St. Paul in Titus i. 12.

Epimetheus, ĕp-ĭ-mē'thūs, in Greek mythology, a son of Iapetus and Clymene, and the brother of Prometheus. Against the latter's advice he married Pandora, who opened the box in which the foresight of Prometheus had hid all the ills by which mortals were liable to be afflicted. All kinds of diseases and torments issued out of the box, and hope alone remained behind. According to other accounts it was Epimetheus himself who opened the box. (See PANDORA.) It is to be remarked that, in the Greek tradition, curiosity and disobedience are made the origin of evil, as in the Mosaic account of the fall.

Epinal, ā-pē-näl, France, town, capital of the department of the Vosges, in a narrow valley on the Moselle, 190 miles east-southeast of Paris. It has a communal college, a public library of 20,000 volumes, a museum, a theatre, and hospital. The manufactures consist of articles in iron and brass, leather, oil, and chemicals; freestone and marble are quarried in the vicinity. Pop. 28,523.

Epinay, ā-pē-nā, **Madame de la Live d'** (LOUISE FLORENCE PÉTRONILLE TARDIEU D'ESCLAVELLES), French writer: b. Valenciennes 11 March 1725; d. Paris 17 April 1783. She was the daughter of M. Tardieu Desclavelles, and married her cousin D'Epinay. But his extravagance soon compelled her to separate from him. During the earlier part of her life she formed an acquaintance with Rousseau, who, quick and susceptible in all his feelings, devoted himself to the fascinating and accomplished woman with an ardor, the depth and strength of which he describes himself in his 'Confessions.' She was not insensible to the homage of her "bear," as she used to call him, on account of his eccentricities, and did all that was in her power to place him in a situation corresponding to his wishes. She gave him a cottage (the Hermitage, since so famous) in her park of Chevrette, in the vale of Montmorency. Here the author of the 'Nouvelle Héloise' passed many days, rendered happy by his romantic attachment to Madame d'Epinay; until he became jealous of Baron Grimm, whom he had himself introduced to her; and in consequence of this feeling, which he took no pains to conceal, a coolness, and finally an aversion, took place between him and the lady, which is but too plainly expressed in his 'Confessions.' A defense of the later conduct of Madame d'Epinay toward Rousseau may be found in Grimm's 'Correspondence,' where an account is also given of some works written by her, of which the most celebrated is 'Les Conversations d'Emilie.' In this the authoress, in a rather cold but neat style, sets forth the principles of moral instruction for children, with equal elegance and depth of thought. It obtained, in 1783, the prize offered by Monthion (the chancellor to the Count d'Artois) for useful works of this kind, in preference to the 'Adèle et Théodore' of Madame de Genlis. She also wrote 'Lettres à mon fils,' and 'Mes moments heureux.' An abridgment of her memoirs, and correspondence, showing her relations with Duclos, Rousseau, Grimm, Holbach, Lambert, etc., appeared in 1818. They give a true picture of the refined but corrupt manners which prevailed among the higher classes in France during the government of Louis XV.

Epior'nis, an extinct ratite bird of Madagascar (*Æpyornis maximus*), interesting not only for itself, but because its remains appear to have formed the basis for the Arabic tale of the gigantic roc. It was much like an ostrich in size and structure, except for the massiveness of its limbs and the extraordinary size of its eggs. These have been found in considerable numbers in muck-swamps, or sometimes floating in the river-mouths, often in perfect condition, and are the largest and strongest eggs known, measuring about 13 inches by 9½. These dimensions are twice those of an ostrich's egg, and an egg of the epiornis would hold the contents of six ostrichs' eggs, yet the epiornis was little if any larger. First made known to science about 1850, so many remains have since been found that about 12 species have been indicated, and a second genus (*Mullerornis*), which has been joined with *Æpyornis* into the family *Æpyornithidæ*. Tradition and the evidences of some bones indicate that these birds were exterminated since human occupation of Madagascar began. See MOA.

Epiphanius, ĕp-ĭ-fā'nĭ-ŭs, **Saint**, Greek father of the Church: b. of Jewish parents near Eleutheropolis, Palestine, about 315; d. at sea near Cyprus 403. In his youth he went to Egypt where at first he came under the influence of teachers of Gnosticism; but afterward he embraced monasticism, and returning to his own country there became head of a community of monks. In Palestine he made the acquaintance of the two western churchmen, Jerome and his associate, Rufinus; the friendship of the three men was cordial and intimate till Rufinus' defense of the teachings of Origen angered Epiphanius, whose special mission seemed to be to obliterate every line written by Origen. He was made bishop of Constantia (the older name Salamis), in Cyprus 367, and held that see till his death. On one occasion, 394, he visited Jerusalem to denounce Origenism. He must have been more than 80 years old, perhaps near 90, when he went to Constantinople to charge the patriarch of that see, Saint John Chrysostom, with the sin of favoring the Origenists, but a few words from Chrysostom opened his eyes. Of his numerous writings few remain; among them: 'Panarion, a history of Heresies'; 'Commentary on the Book of Canticles,' and some others. Consult: Tillemont, 'La Vie de S. Epiphane, avec l'Analyse des Ouvrages de ce Saint, et son Apologie.'

Epiphany, ē-pĭf'a-nĭ, a festival of the Catholic Church held on 6 January to commemorate the manifestations of Jesus Christ as son of God: (1) to the Wise Men of the East (Magi) at Bethlehem; (2) at his baptism by John in the Jordan, when the voice from heaven proclaimed, "Thou art my beloved son; in whom I am well pleased"; (3) at the marriage feast at Cana in Galilee, where Jesus wrought his first miracle. The observance of this festival can be traced to an earlier period in the eastern Church than in the western. In the Greek Church it was observed as early as the 2d century, but the event commemorated by the Greeks was not the visit of the Magi to Nazareth, but the manifestation of Jesus at the Jordan as the Messiah. Not till the 4th century does the Epiphany appear to have been observed in the Latin Church. In the Greek and Oriental churches it is customary to administer baptism on the eve of this festival with unwonted solemnity: this because of the relation of the festival to the baptism of Jesus by St. John. In those churches, too, the Epiphany (Epiphaneia, Theophaneia) was the festival commemorative of the birth of Jesus; for it was believed that the baptism in Jordan took place precisely on the 30th anniversary of the birth. A popular name for this festival in English is "Twelfth Day," that is, twelfth day from Christmas; it is also called "Little Christmas." In various other languages it is known as "Three Kings' Day," or "Day of the Kings." See MAGI.

Epiphyllum, ĕp-ĭ-fĭl'ŭm, a genus of plants of the natural order *Cactaceæ*. The few species seem to be confined to Brazil, where they are epiphytic upon trees. They have flat-jointed stems with blunt ends, from which the new branches and flowers are produced. These are borne in great abundance, on which account, and because of their brilliant red tints, this group of cacti is exceptionally popular in greenhouses, being probably the most useful of all cacti. They are easily propagated by means of cuttings or by grafting, particularly upon erect-growing species of other genera, and are generally used as hanging-basket plants, for which purpose their drooping habit specially recommends them. They need a porous, poor, fibrous soil and little water. The species most widely grown are *E. truncatum*, the crab or Christmas cactus, with numerous horticultural hybrids between it and related species, and *C. Gærtneri*, the Easter cactus.

Epiph'ysis. See BONE.

Epiphyte, ĕp'ĭ-fīt, or **Air-plant**, a plant attached to a tree or other support, organic or inorganic, living or dead, but from which it obtains no nutriment. The term air-plant has been popularly applied because these plants are typically neither parasitic, saprophytic, nor terrestrial, but depend upon the dust which lodges around them and upon the water of dew and rain. Strictly speaking, they are not air-plants, because this term implies no other source of life than air. Besides the typical epiphytes, which have representatives in many plant families, particularly the tropical orchids, bromelias, and ferns, there are many forms which are only partially epiphytic. In structure many of them exhibit adaptations for checking transpiration and for securing even minute quantities of water from the air or from objects to which they are attached. (See PITCHER-PLANTS.) Others (certain orchids) have storage organs which are usually specialized stems. Some have roots which serve only to anchor the plants to their support. In these, which are the most typical, the absorption of food takes place in the leaves and other green parts. Others are only epiphytic at first, since they later develop true roots which obtain food from the soil. The home of the largest number of epiphytes is in the moist region covered by tropical forests, the trees of which are often so covered with these plants that their branches are wholly concealed by a very miscellaneous growth. In the temperate and colder climates the epiphytal forms are confined almost wholly to lower orders of plant life such as liverworts, mosses, algæ, and lichens. These are also represented in the tropics, some of them even becoming attached to leaves of higher plants. Many of the flowering epiphytes are cultivated in greenhouses for ornament. Among the favorites are various species of *Nepenthes* (q.v.), orchids, and bromelias. One of the best-known American species, common in the southern United States, is the so-called Florida or Spanish moss (*Tillandsia usneoides*) of the natural order *Bromeliaceæ*.

Epirus, ē-pī'rŭs, a province of ancient Greece. It was separated from Grecian Illyria by the Ceraunian Mountains, and by the famous river Pindus from Thessaly. The river Acheron, also famous in mythological story, flowed through the limits of this province, and here were also the celebrated temple and sacred oak grove of Dodona, famous for its oracles. Pyrrhus, king of Macedon, was a native of Epirus, which country passed successively into the hands of the Romans and the Turks. It was ceded to Greece by the Turks in 1881. See GREECE.

Epis'copacy, that form of Church government in which one order of the clergy is superior to another; as bishops to priests and deacons. Much discussion has taken place on the subject of episcopacy. Nothing conclusive can be gathered concerning it in the New Testament; but there can be no doubt that it existed universally in the Church from the earliest historic ages down to the time of the Reformation, and it is inferred, as no change can be shown to have taken place, that the same constitution existed from the time of the apostles. Presbyterians and others argue, on the other hand, that, as there is nothing definite concerning it in Scripture, Christians are left a discretionary power of modeling the government of their Church in such a manner as may seem to them most meet; and that every Christian society has a right to make laws for itself, provided these laws are consistent with charity and peace, and with the fundamental doctrines and principles of Christianity. The power vested in the bishops or higher clergy differs very much among the different episcopal bodies. The Roman Catholic and the Greek Churches, as also the Church of England and the Methodist Church, are espicopalian. See BISHOP; ENGLAND, CHURCH OF; GREEK CHURCH; METHODIST CHURCH; CATHOLIC CHURCH, ROMAN.

Epis'copal Church. See ENGLAND, CHURCH OF; METHODIST EPISCOPAL CHURCH; PROTESTANT EPISCOPAL CHURCH; REFORMED EPISCOPAL CHURCH.

Episcopal Church, Reformed. See REFORMED EPISCOPAL CHURCH.

Episcopal Theological School, an institution situated at Cambridge, Mass. It was established in 1867 by Benjamin Tyler Reed, as a college for candidates studying for the ministry for the Episcopal Church. Students holding bachelors' degrees may obtain the degree of B.D., but those not holding such a degree receive only certificates.

Episcopal Theological Seminary, the name of an institution in Alexandria, Va., founded for the education of candidates for the ministry of the Protestant Episcopal Church. It was chartered in 1854, although the school was founded in 1823. Several scholarships have been established for worthy students. One of its renowned pupils was Phillips Brooks (q.v.).

Episco'pius, Simon, Dutch theologian: b. Amsterdam 1 Jan. 1583; d. there 4 April 1643. The religious movement known as Arminianism was fostered by him, and he was its leader after the death of Arminius. He was educated at Leyden, where in 1606 he received his degree of M.A. In 1610 he was ordained pastor at the village of Bleyswyck near Rotterdam. In 1611 the states-general, with the intention of putting an end to the agitations created by the controversies between the Gomarists or Calvinistic party and the Arminians or Remonstrants, ordered a conference to be held in their presence at The Hague between six ministers of each party. Episcopius was one of the six charged with the advocacy of Arminianism, and highly distinguished himself by good temper, ability, and learning. In 1612, the curators of the University of Leyden appointed him professor of theology in place of Gomar, who had gone to Seeland. This enraged the leaders of the orthodox party, who accused Episcopius of Socinianism, and of having entered into an alliance with the Roman Catholics for the destruction of Protestantism. By this the fanaticism of the populace was roused; he was insulted and abused in the street, and on one occasion narrowly escaped being stoned to death. The house of his brother in Amsterdam was sacked, under the pretext that it was a rendezvous of the Remonstrants. In 1618 occurred the famous Synod of Dort. Episcopius was present, with several other Arminians. The Calvinists, who were in an overwhelming majority, would not allow him to speak; they told him that the synod was met not to discuss, but to judge; and all the proceedings exhibited much bigotry and tyranny. Expelled from the church, and banished from the country, Episcopius betook himself first to Antwerp, afterward to Rouen and Paris, but 1626 returned to Rotterdam, where the *odium theologicum* against his party had become less virulent. Here he married in 1630, and four years later was made primarius professor of divinity in the newly established college of the Remonstrants. Episcopius held enlightened principles in regard to religious toleration. Not placing a high value on merely doctrinal views, but trusting rather to the efficacy of the Christian spirit to elevate and purify the character, and seeing, moreover, the presence of this spirit in men holding the most conflicting opinions (when not inflamed with controversial hates), he was desirous of a broader and more catholic bond of unity among Christians than the opinionative creeds of his day permitted. He wrote 'Institutes of Theology'; 'Apology'; 'Confession,' etc. See Calder, 'Memoirs of Simon Episcopius' (1838).

Episode (Lat. *episodium*, from the Gr. ἐπεισόδιον, *epeisodion*, something adventitious). This term is employed by Aristotle in two significations. Sometimes it denotes those parts of a play which are between the choruses, and sometimes an incidental narrative, or digression in a poem, which the poet has connected with the main plot, but which is not essential to it. In modern times it has been used in the latter sense only. With the best poets the episode is not an unnecessary appendage, serving merely to swell the size of the work, but is closely connected with the subject, points out important consequences, or develops hidden causes. Of this kind is the narrative of the destruction of Troy, in Virgil's Æneid. This was the cause of the hero's leaving his country; but the poet does not commence with it because he wishes to bring the plot into a narrower space. He therefore inserts it in the course of the story, but so skilfully that we expect it in this very place; and it not only serves as a key to what has gone before, but prepares us for what is to come, namely, the passion of Dido. In this way the episode becomes an essential part of the whole, as it must necessarily be, if it is of any importance to preserve the unity of the poem. So with the tale in Wieland's 'Oberon'; it appears incidental, but explains to us the reason of Oberon's singular interest in the fate of

Huon. In epic poetry there is much more room for the episode than in dramatic, where the poem is confined to a present action. An excellent instance of the skilful use of the episode in the modern novel is given in Manzoni's I promessi sposi, in the tale of the 'Nun of Monza.' The term episode has also been transferred to painting, especially historic painting, in a sense analogous to that which it has in poetry.

Epistaxis. See NOSEBLEED.

Epistemology (ἐπιστήμη, knowledge or science, and λόγος, theory or discourse), or theory of knowledge, is an account of the nature of knowledge, treating of its origin and laws of development, its validity and relation to human experience as a whole. Investigations of this character fall within the field of general philosophy, and have usually been included under the heading of metaphysics. The word «Epistemology» is said to have been first used by J. F. Ferrier in his *Institutes of Metaphysics* (1854). Since its general adoption it has sometimes been taken to denote a field of inquiry co-ordinate with, and largely independent of, Metaphysics. It has been proposed to keep the investigation of the nature of knowledge distinct from the problems regarding the nature of being, and to call the former epistemology, and the latter metaphysics. The best usage of the present time, however, seems to retain the historical sense of the term metaphysics as the name for the more general field of philosophical inquiry which embraces both epistemology and ontology. (See also articles on PHILOSOPHY and METAPHYSICS.) Moreover, a logical justification for this usage is furnished by the fact that it is impossible to carry on the two branches of inquiry in isolation. It must undoubtedly be granted that for an ultimate ontology, or final view of the world, it is necessary to go beyond the merely cognitional aspect of experience and include in our synthesis judgments based on other orders of value than the merely logical. But it is at once obvious that we cannot take one significant step in investigating the nature of reality without some criterion of knowledge, *i. e.*, some theory of the conditions under which reality is known, and of what constitutes truth. It is perhaps not so evident that the nature of knowledge cannot be made the subject of inquiry without any reference to metaphysical theory. Indeed, it is not uncommon to speak of epistemology, as Locke does, as «a preliminary clearing of the ground» which is to be completed before any more ultimate metaphysical inquiries are to be undertaken,— if, indeed, these are to be undertaken at all. But this way of conceiving the matter is quite misleading. The figures which compare the knowing faculty to an instrument whose nature must first be understood, are here quite inapplicable. For knowledge has no existence by itself, or apart from and external to its objects. What we want, as Hegel has observed, «is to combine in our process of inquiry the action of the forms of thought with a criticism of them. The forms of thought must be studied in their essential nature and complete development; they are at once the object of research and the action of that object. Hence they examine themselves; in their own action they must determine their limits and point out their defects.» In other words, knowledge is never a mere series of ideas or mental representations that can be investigated apart from its relation to objects. In so far as it is knowledge it refers to and implies reality. To investigate its nature, then, is at the same time to test its conclusions regarding the nature of the objects with which it deals. But even if one refuses to take this standpoint, one must still admit the close connection of epistemology and metaphysics. For all theories of the nature of knowledge are based implicitly or explicitly on certain metaphysical assumptions regarding both the mind which knows and its relation to the objects known. Epistemology, then, cannot take one step without involving the ontological problems which some of its representatives seek to avoid.

It is likewise impossible to distinguish sharply the discussion of epistemological problems from logic. If a division can be made at the present time it is only in degree of ultimateness. It is possible, though perhaps not advisable, to limit the term «logic» to the somewhat narrow and abstract treatment which takes as its object the discovery of certain correct forms of thinking, or certain rules which are of practical value in testing arguments. When, however, logic breaks away from this narrow programme, as has been done by the more important recent writers, and carries on its inquiries in a philosophical spirit, it becomes identical with epistemology. Epistemology, logic, and metaphysics may thus be said to denote certain main points of view, differing somewhat in the treatment of various writers in emphasis and inclusiveness, rather than three independent and isolated sciences.

Psychology, as a natural science, however, occupies a different field, and has quite a different problem from epistemology. It is true that attempts have frequently been made to explain knowledge by beginning with cognitive mental states viewed as psychological processes. But the characteristics of the mental states and functions with which psychology deals have no immediate bearing on the problem of knowledge. For psychology is concerned only with the mode in which ideas exist; it investigates their quality, duration, intensity, etc., as well as their various modes of combination, viewing them as particular forms of psychical reality. Epistemology, on the other hand, is interested not in the existential aspect of ideas, but in their significance, in the universal and objective validity of experience as a body of truth. It thus seeks to bring to light the forms and functions of intelligence, noting the conditions and presuppositions under which it works, and the laws by which knowledge develops from its simpler and more fragmentary stages to the more complicated and coherent structure of science. It is a philosophy of experience rather than a description of individual states of consciousness.

Reflection on the nature of knowledge does not arise until a somewhat late stage in the development of the thought of the individual and the race. Thought first announces its conclusions confidently and fearlessly. It is not until this naïve confidence fails and scepticism arises that it is forced to reflect upon the nature of knowledge and its grounds of certainty. This is illustrated in the history both of ancient and of modern philosophy. The early Greek philosophers, as Hegel remarked, thought away fearlessly regarding the nature of reality. It was the collapse of those early systems and the scepticism of the Sophists (q.v.) which forced Socrates to take up the epistemological problem. In the same way the Stoic and Epicurean discussions regarding the canon of truth arose in response to the more outspoken and thorough-going scepticism of later times. In modern times the epistemological interest did not come into the foreground until Locke's 'Essay.' Locke's account of the origin of this work brings out very clearly the way in which problems of this character naturally arise: "Five or six friends meeting at my chamber, and discoursing on a subject very remote from this, found themselves quickly at a stand by the difficulties that rose on every side. After we had awhile puzzled ourselves, without coming any nearer a resolution of those doubts which perplexed us, it came into my thoughts that we took a wrong course, and that before we set ourselves upon inquiries of that nature, it was necessary to examine our own abilities and see what objects our understandings were, or were not, fitted to deal with . . . . Some hasty and undigested thoughts on a subject I had never before considered, which I set down against our next meeting, gave the first entrance into this discourse; . . . . and at last it was brought into that order thou now seest it."

Kant's 'Kritik of Pure Reason' was the work which placed epistemology in the foreground of continental philosophy. In the Preface to that work, he shows that the motives that led to his undertaking were very similar to those which influenced Locke. The scepticism of his time, he says, "is clearly the result, not of the carelessness, but of the matured judgment of an age, which will no longer rest satisfied with the mere appearance of knowledge. It is, at the same time, a powerful appeal to reason to undertake anew the most difficult of its duties, namely, self-knowledge, and to institute a court of appeal which should protect the just rights of reason, but dismiss all groundless claims, and should do this not by means of irresponsible decrees, but according to the eternal and unalterable laws of reason." Kant has a poor opinion of Locke's account of knowledge, and characterizes it as "a certain physiology of the human understanding." He himself proposed to inaugurate a method of Criticism which should give a new direction to philosophical inquiry, and at the same time furnish to it a sure foundation for further advance. Since Kant's time epistemological problems have largely dominated modern philosophy; and indeed, it has been maintained by many thinkers that the criticism of knowledge is the sole function which philosophy is able to perform, and that ontological speculation is vain and fruitless.

In the Pre-Kantian philosophy Rationalism (q.v.) and Empiricism (q.v.) were the main types of epistemological theory. The basis of the former was laid by Descartes (q.v.), who sought to universalize the method of mathematics, and by this means to secure the certainty of absolute demonstration in all fields. As mathematics starts from axioms and principles which are intuitively certain, and proceeds by means of reasoning to deduce all its other propositions from these as necessary consequences, so all science must derive its conclusions from fundamental and indemonstrable principles. These principles exist in the mind as *a priori* truths, and are universal and necessary in character. All science is thus built up by reasoning from general principles. Sense-perception and observation of particular facts were neglected, since it was held to be impossible to arrive in this way at the universal and necessary form of truth which science demands. It is evident that this theory of knowledge could more readily be applied to the general features of reality than to a determination of its particular details. And in the hands of Wolff (q.v.) and other continental rationalists it was occupied mainly in furnishing formal proofs of the existence of God, the nature of the soul, and the external features of the physical universe. Empiricism (q.v.), on the other hand, emphasizes sense-perception as the basis of all knowledge. Experience is described as a series of particular sensations and ideas in consciousness which are given to the mind from some external source. The mind itself is regarded as merely receptive, without any store of innate ideas, or of organizing principles. It was not strange, then, that in the hands of a genius like David Hume (q.v.), who carried this point of view to its logical outcome, empiricism should issue in scepticism. For if experience is nothing but a series of conscious states, each of which is "loose and separate" from all the others, it is impossible to know anything except these particular states in their isolation; impossible, therefore, to reach any universal propositions such as science demands. Again, if knowledge is limited to states of consciousness, it follows at once that there can be nothing known either of the nature of objects or of the subject or soul.

Kant (q.v.) did much to overcome the one-sidedness of these theories, and to give a more adequate account of the nature of knowledge. For, while he insists that knowledge must begin with experience, he points out that experience itself is a compound, implying both a given sense material and forms and principles of organization on the part of the mind. By his doctrine that "thoughts without perceptions are empty, while perceptions without thoughts are blind," he passed beyond the one-sided views of both Rationalism and Empiricism. By his transcendental method of inquiry he seeks to show what are the fundamental forms and categories which the mind employs in building up a coherent and universally valid system of experience. But, in spite of the great reform which he effected, he did not wholly succeed in reaching an organic view of experience. This was partly the result of presupposition which he inherited from the past, and partly due to his own tendency to make hard and fast divisions and distinctions. There always remained for him an unresolved dualism within experience between the datum of sense and the forms of thought. Again, thought, as he conceives it, does not pass beyond subjectivity and include in itself the nature of its object, but is occupied with bringing order and unity into sensations and mental representations. Although these states of consciousness, when thus acted upon by thought, become objective in the sense that they are parts of a universal and necessary system, nevertheless they are still only "phenomena," objects in the mind, while the world of real being (the things in themselves) remains inaccessible to knowledge. The spirit of Kant's philosophy undoubtedly leads beyond any such absolute dualism. But from Kant's day to the present time this distinction has appeared the final word of philosophy to many thinkers who continue to accept the presuppositions and categories of the past century, and who fail to apply to this problem the organic and evolutionary conceptions which are now within their reach.

Modern epistemological investigation may be described as seeking to exhibit the organic unity of experience. To reach this result, new theories regarding the nature of the mind and its relation to objects are necessary. In the first place, the conception of the mind as made up of a number of distinct faculties, must give place to the idea of the mind as a unitary system of functions which mutually coöperate and determine each other in the progressive development of experience. Secondly, the mind can no longer be regarded as a system of merely subjective functions related only in an external and accidental way to the real world of objects. The course of philosophical discussion has rendered it evident that if we begin by defining experience in terms of mental processes there is no way of deriving from these the world of objects. If our epistemological theory is to be adequate to experience as we know it, objectivity must be included within it. Thought, that is, is real only as a relation to objects; by itself, and apart from the world of real objects, it has no reality. It is only by thus recognizing from the beginning the essential relation of subject and object that it is possible to exhibit the real organic unity of experience as a system of knowledge. It was Kant's successors in Germany, and preeminently Hegel (q.v.), who first developed this organic view of experience. But partly on account of the form in which these systems were expressed, and partly as a result of the decline of philosophical interest, their most valuable and characteristic ideas failed for a long time to be appreciated. The credit of freeing these fruitful ideas from the somewhat obscure and uninviting form in which they were presented in the German systems of a century ago, belongs in the main to the English Neo-Hegelians and their co-laborers in America, among the latter of whom a place of honor must be given to Dr. William T. Harris, the late U. S. Commissioner of Education. The fundamental doctrine of these writers is that what is real is rational, *i. e.*, knowable in terms of reason, and therefore that all forms of cognitive experience can be exhibited as organically interconnected as a system of rational ideas or meanings. Conscious experience is from the first regarded, not as a series of psychological states, but as taking the form of a judging activity whose function is to interpret and reveal the nature of the objective world. Moreover, knowledge proceeds in its development through differentiation and integration in accordance with the fundamental laws of logical evolution. Its later and more highly developed forms are then to be understood as the differentiation and systematization of its more elementary forms and functions. The final truth regarding the nature of the real world must accordingly correspond with the ideal of completely developed and perfectly rationalized experience. As representatives of this general type of objective Idealism we may mention the late T. H. Green, Edward Caird, the late D. G. Ritchie, A. S. Pringle-Pattison B. Bosanquet, W. T. Harris, John Watson, and Josiah Royce.

There are, however, prominent philosophical writers of the present day who employ to some extent Hegelian methods and principles in dealing with experience, but who yet maintain that the account of knowledge in terms of reason requires to be modified and supplemented in various ways. Two main points of view may be here mentioned, which have much in common, and which are both often emphasized by the same writers. On the one hand, it is claimed that logical thinking operates with universal concepts, and can therefore never do justice to the individual aspects of real objects. Thought, in other words, is concerned only with universal relations, and is unable to apprehend the uniqueness and particularity of real existence; it gives us only descriptions of things in general terms, and has to receive as a datum from another form of knowing the particular facts which form its subject-matter. This latter aspect of reality, it is maintained, can be apprehended only in some form of immediate experience. In fact, it is often maintained that logical experience must both start from and pass into direct intuition or feeling. In its beginning, logical thinking presupposes the awareness of objects in sense-perception; for it is claimed it is only in this way that thought comes into contact with individual things and gets a foothold in reality. Again, since the total system of things must exist in individual form, the final synthesis of knowledge must transcend logical relations and be realized, if it can be attained at all, in immediate intuition—a mode of cognition that may perhaps be described as analagous to æsthetic contemplation. Although the neo-Hegelian writers have not been backward in meeting these arguments, and have successfully shown the difficulties involved in their opponents' antithesis of universal and individual, of thought and immediate knowing, yet the discussion cannot be regarded as closed at the present time.

In a similar spirit the function of will and purpose as a fundamental element in experience is at present emphasized in many quarters. The intellectual or rationalistic account of cognitive experience is maintained to be inadequate, since it abstracts from the volitional element which alone gives to knowledge its function and significance. Concrete experience is the process of living, and living consists in the realization of purposes. So much may, I think, be granted: experience is essentially a teleological process and must be interpreted in terms of purpose. But purposes are only defined and realized through thought. Pragmatism (q.v.) (as the popular theory of the present day is called) goes further, and interprets knowledge solely in its relation to action. Knowledge is the instrument which the will employs to discover the means whereby practical purposes may be realized. It is thus never an end in itself, nor does its function consist in revealing the nature of a reality beyond experience. The function of thought is to effect the practical control of experience, and the only realities which it can define are terms within experience itself. Its problems are set by the particular situations and concrete demands which the developing process of experience presents. There is no intelligible problem regarding the nature of reality in general, or reality that does not exist as a particular functional element in concrete experience. Against this position various objections have been urged by many writers; the chief of which are: (1) that it does not reach a real organic unity of experience; (2) that it overlooks the fact that knowledge is an end in itself; (3) that it is subjective, and fails to recognize the objective and rational ends without which no real experience can exist.

At the present time perhaps the most important function of Epistemology consists in a criticism and evaluation of the fundamental conceptions and principles which underlie the procedure of the special sciences. These sciences set out from certain definite assumptions regarding the nature of the phenomena which they investigate, and with certain demands which their method of investigation has to fulfil. It is the function of Epistemology to make explicit the nature of these initial assumptions, and to show that the accounts given by these sciences are essentially determined by the character of these assumptions. Instead of assuming that the results of the special sciences are to be accepted at their face value as direct statements about the nature of reality, both philosophical epistemologists and workers in these sciences who have reflected on the problems of method (as *e. g.*, E. Mach and Karl Pearson) now agree that the view of the world given by natural science —and especially the mechanical theory—is itself a logical construction, based on certain assumptions which are necessary to carry out the purpose of the scientific co-ordination and explanation of facts. This construction must not be read apart from the purpose for which it was designed. Indeed, the prevailing tendency is to emphasize the merely methodological character of scientific results to such an extent as to make them appear almost arbitrary and devoid of any ontological significance. This is undoubtedly an extreme position. It must, of course, be admitted that the results of the special sciences are largely hypothetical and possess only relative truth. But they are never mere logical constructions in the sense that they are entirely divorced from reality. The ultimate purpose of science, as of all thinking, is to exhibit the structure of the real world, and the assumptions and hypotheses of the special sciences derive their significance and justification solely from their employment as means for the accomplishment of that end. In its task of criticising the assumptions of the special sciences, then, Epistemology cannot escape the consideration of metaphysical problems regarding the nature of the external world and its relation to the human mind.

Bibliography.—The bibliography of this subject is coextensive with that of general philosophy. A few works may be mentioned which deal with the more recent development of the subject:—Ormond, 'Foundations of Knowledge' (1894); Ladd, 'Philosophy of Knowledge' (1897); James, 'The Will to Believe'; Ward, 'Naturalism and Agnosticism'; Rickert, 'Die Grenzen der naturwissenschaftlichen Begriffsbildung' (1902); Münsterberg, 'Psychology and Life' and 'Die Grundzüge der Psychologie'; Dewey, 'Studies in Logical Theory' (1902); Seth, 'Epistemology and Metaphyics' and 'The Problem of Epistemology' (*Philosophical Review*, Vol. I, 1892); Seth, 'The Utilitarian Estimate of Knowledge' (*Philosophical Review*, Vol. X, 1901); Creighton, 'Methodology and Truth' (*Philosophical Review*, Vol. X, 1901); Albee, 'The Significance of Methodological Principles' (*Philosophical Review*, Vol. XV, 1906).

James E. Creighton,
Professor of Philosophy, Cornell University.

Epistolæ Obscurorum Virorum, ē-pĭs'tō-lē ŏb-skū-rō'rŭm vī-rō'rŭm (Lat. "Letters of obscure men"), a collection of satirical letters which appeared in Germany in 1515-19, and professed to be the composition of certain ecclesiastics and professors in Cologne and other German towns. It is considered one of the most masterly sarcasms in the history of literature, and its importance is enhanced by the effect it had in promoting the cause of the Reformation through its attacks upon scholastics and monks. The authorship of this satire has been a fertile subject of controversy, but the major portion has been attributed to Reuchlin, Ulrich von Hutten, and Erasmus. The best edition is that of Böcking, supplementing his edition of the works of Hutten (Leipsic 1864-70).

Ep'itaph (Gr. ἐπιτάφιος, *epitaphios*, funeral, from ἐπι, *epi*, upon, and τάφος, *taphos*, tomb), an inscription upon a tomb. The earliest known are those upon Egyptian sarcophagi. Epitaphs were in use among both the Greeks and Romans. Many of the later Greek epitaphs were of considerable length, while those of the Romans commonly recorded only brief particulars regarding the deceased. The tombs of the Romans were placed near the highways, and their epitaphs generally commenced with, *Sta viator!* (Stop, traveler!). On Christian tombstones, epitaphs frequently express the pious hopes of survivors in reference to the doctrines of the Christian faith. In the catacombs of Rome, which were made a place of refuge by the persecuted Christians under the pagan emperors, are many remarkable epitaphs of this description.

Among memorable epitaphs, one of the happiest is that of Sir Christopher Wren, in St. Paul's, London, of which he was the architect:

Si monumentum quæris, circumspice.
"If you seek for his monument,—look about you."

The following is the epitaph of a Roman matron:

Domum servavit,
Lanam fecit.
"She kept the house and span the wool."
Sta, viator: heroem calcas,—
"Traveler, pause: thou treadest upon a hero,"

has been ascribed both to Montecuculi and to Gen. Merci.

Sufficit huic tumulus, cui non suffecerat orbis,—
"This tomb suffices for him for whom the world did not suffice,"

was the epitaph of Alexander the Great.

Count Tessin, a governor under Gustavus III. of Sweden, ordered the words

Tandem felix —
"Happy at last."

to be inscribed on his tomb. The following is Sir Isaac Newton's epitaph:

Isaacum Newton,
Quem immortalem
Testantur Tempus, Natura, Cœlum,
Mortalem hoc Marmor
Fatetur.
"This marble acknowledges Isaac Newton mortal, to whose immortality time, nature, and heaven bear witness."

St. Anne's Church, at Cracow, has the following suggestive epitaph, dedicated by Count Sierakowski to Copernicus:

Sta, sol, ne moveare.
"Stand, O sun! move not."

Many so-called epitaphs are merely epigrams, never intended for serious use as monumental inscriptions. Among such may be cited that of Piron, on Marshal de Belle-Isle, who was buried next to Turenne:

Ci-git le glorieux à côté de la gloire,
"Here beside glory lies the vainglorious."

For Greek inscriptions consult the 'Corpus Inscriptionum Atticarum' (Berlin 1878–82); for the Latin, the great 'Corpus Inscriptionum Latinarum' (Berlin 1863, et seq.); for those of modern times, Andrews, 'Curious Epitaphs' (London 1883).

Epithalamium, ĕp"ĭ-thā-lā'mĭ-ŭm, (Lat., from the Gr. ἐπιθαλάμιος, *epithalamios*, nuptial, from ἐπί, *epi*, upon, and θάλαμος, *thalamos*, a chamber), a nuptial song. Among the Greeks and Romans it was sung by young men and maids at the door of the bridal chamber of a new-married couple. It consisted of praises of the bridegroom and bride, with wishes for their happiness. Examples may be seen in Theocritus' epithalamium of Helen, and the three epithalamia of Catullus, in which the Greek form is much modified. Some Roman epithalamia were collected by Wernsdorf in Vol. IV. of his 'Poetæ Latinæ Minores' (Helmstedt 1789).

Epithelium, ĕp-ĭ-thē'lĭ-ŭm, one of the simplest forms of epithelial tissue, characterized by its non-vascularity, and consisting of flattened or columnar cells united into continuous membranes by an intercellular cement substance. Epithelium serves for the most part to protect exposed surfaces of the body, and performs the functions of absorption, secretion, and excretion. The epithelial tissues are developed from all three layers of the developing embryo. They themselves secrete their own cement substance. This takes on the form of thin plates between the cells, gluing them together. Occasionally the epithelial cells develop short lateral projections (prickles), forming with similar structures of neighboring cells intercellular bridges, between which are intercellular spaces filled with lymph for the nourishment of the cells. Inasmuch as practically all epithelial cells have one exposed surface and one surface lying in contact with tissues beneath, the upper and lower surfaces show certain variations of structure. Occasionally the free surface develops fine hairs or cilia. These are found in various localities. The outer surface of the cell, being exposed, develops more truly animal functions, the inner more vegetative. Blood vessels and lymph vessels do not penetrate, as a rule, into epithelial tisues, but they are richly supplied with nerve-end organs.

According to their shape and relation, the epithelial cells are divided into these varieties: (1) Simple epithelial cells, with or without cilia, comprising (a) squamous epithelium; (b) cubical epithelium; (c) columnar epithelium; (d) pseudostratified columnar epithelium. (2) Stratified epithelium, comprising (a) stratified columnar epithelium, with superficial flattened cells without cilia; (b) transitional epithelium; (c) stratified columnar epithelium. (3) Glandular epithelium. (4) Neuro-epithelium.

1. *Simple Epithelium.*—This is that type in which the cells lie in a single continuous layer. This form is found lining almost the entire alimentary tract, the smaller air-passages, the majority of the gland-ducts, the ovarian ducts, the uterus, the central canal, the spinal cord, and the ventricles of the brain. In (a) simple squamous epithelium the cells are flattened, forming a mosaic with the nuclei lying in the middle of the cell. It is found in the alveoli of the lungs. In (b) simple cubical epithelium the appearance is that of short polyagonal prisms. It occurs in the smaller bronchioles of the lung, in certain portions of the uriniferous tubules, the liver, pancreas, salivary and mucous glands. In (c) simple columnar epithelium the cells are pyramidal or prismatic. This type is found in the intestinal tract from the cardiac end of the stomach to the anus, and in certain portions of the kidney. Ciliated columnar is found in the ovarian duct and uterus, in the central canal of the spinal cord, and in some of the smaller bronchi.

2. *Stratified Epithelium.*—When the cells of simple epithelium increase to such an extent that layer upon layer is developed, the epithelium no longer remains simple, but becomes stratified. The lower layers are richly supplied with blood vessels, and multiply very rapidly, pushing out the upper layers that are constantly dying and being cast off. The various forms are: (a) Stratified columnar epithelium, with superficial flattened cells, forming the outer covering of the body, the epidermis and its continuations inside of the body, as, for instance, the walls of the œsophagus, the epithelium of the conjunctiva, the external auditory canal, the sheath of the hair-follicles, the walls of the rectum, the anus, and the vagina. The deeper cells are usually cubic-cylindrical, and are followed, as a rule, by one or more layers of sightly flattened cells, until finally the outmost layers become very much flattened and horny, or they may be developed into distinct horn-like substances such as that found in the nails. (b) Transitional epithelium, a type of stratified epithelium found in the kidney, uterus, urethra, and bladder. It is somewhat similar to the stratified columnar epithelium, but does not show the characteristic deep papillæ in the basal membrane, so characteristic of the former. (c)

Stratified columnar epithelium, consisting of a superficial layer of columnar cells and deeper layers of irregular, triangular, cubical or spindle-shaped cells. This type is found in the larger duct-glands, in the mucous membrane of the nose, portions of the male urethra, and in parts of the larynx. Many of this type of cells have cilia, particularly those found in the back of the nose, larynx, respiratory tract, larger bronchi, Eustachian tube, epididymis, and portions of the vas deferens.

3. *Glandular Epithelium.*—This is a type of epithelium occasionally found scattered among other epithelial cells, and which shows the characteristic of gland-structures. See GLANDS.

4. *Neuro-epithelium.*— Neuro-epithelial cells are highly specialized cells in which the nerve-end organs are to be found. See NERVE-END ORGANS.

Consult: Boehm and Davidorff, 'Text-book of Histology' (1900).

Epizo'a, in a general sense, external parasites, as contrasted with Entozoa, or internal parasites. These are not exact terms in scientific classification. Among them are the fleas, lice, ticks, itch-mites, and similar minute "vermin" infesting man or beast.

In a more restricted sense the term is applied to the degraded, distorted copepod crustaceans parasitic upon the skin, gills and other parts of marine animals, especially fishes. See FISH-LICE.

Epoch, or **Era** (Gr. ἐποχή, *epoche,* epoch, pause). In history, a fixed point of time, commonly selected on account of some remarkable event by which it has been distinguished, and which is made the beginning or determining point of a particular year from which all other years, whether preceding or ensuing, are computed. Some writers distinguish between the terms epoch and era. According to them, both mark important events, but an era is an epoch which is chronologically dated from; an epoch is not marked in this way. The birth of Christ was thus both an epoch and an era from this point of view.

The more important historical epochs are here enumerated. For further details on the mode of reckoning see CALENDAR.

The Creation.— The biblical record of the creation has formed the foundation of numerous chronologies. Of course the authorities (Jewish and Christian) on these various modes of reckoning do not agree as to the time signified by the common authority for the event dated from. The more important of these epochs, of which there are about 140 different varieties, are: (1) The epoch adopted by Bossuet, Ussher, and other Catholic and Protestant divines, which places the creation in 4004 B.C. (2) The Era of Constantinople (adopted by Russia), 5508 B.C. The civil year begins 1 September, the ecclesiastical year about the end of March. (3) The Era of Antioch, used till 284 A.D., placed the creation 5502 B.C. It was merged in the following year in (4) The Era of Alexandria, which made the creation 5492 B.C. This is also the Abyssinian Era. (5) Jewish Era. The common era of the Jews places the creation in 3760 B.C. Their year is lunar-solar, that is, lunar with intercalary months, forming a cycle of 19 years, of which 12 have 12 months and 7, 13 months. The year thus varies from 353 to 385 days. The civil year begins with the new moon following the autumn equinox. The eras dating from the creation are distinguished by the initials A. M. Const., Abyss., etc., are sometimes added to distinguish the particular epochs.

Julian Period.— This begins 4713 B.C. It is an arbitrary epoch, fixed for the purpose of computing all dates forward, as in the case of the creation epochs.

The Olympiads.—The Greeks computed their time by periods of four years, called Olympiads. Their year was lunar, with intercalary months. The first Olympiad, being the year in which Corœbus was victor in the Olympic games, was in the year 776 B.C. The period of the commencement of the year, which was variable, was about July. The contraction used for the Olympic epoch is Olymp.

The Roman Era (Ab Urbe Condita).— The Romans dated from the supposed era of the foundation of their city, 21 April, in the third year of the sixth Olympiad, or 753 B.C. (according to some authorities 752 B.C.). This epoch is designated by the initials A. U. C. The Roman mode of computation was the foundation of our modern chronology.

Era of the Seleucides.—Begins 1 Oct. 312 B.C., the epoch when Seleucus I. (Nicator) took possession of Babylon. The year consisted of 365 days, with a leap year every fourth year. This era is used in the book of Maccabees.

Spanish Era.— This dates from 1 Jan. 38 B.C. The months and days were the same as those of the Julian calendar. It was disused in Aragon in 1350; in Valencia, 1358; in Castile, 1383; in Portugal, about 1415.

Christian Era.—Our mode of computing from supposed data of the birth of Christ, was first introduced in the 6th century, and had not been generally adopted until the year 1000. Since the first year of the 1st century was 1 A.D., the last year of the same century was 100 A.D. Similarly the year 1900 A.D. was the last year of the 19th century. The same holds good in reckoning backward. For particulars of the mode of reckoning the years of the Christian era and the changes which it has undergone, see CALENDAR.

Armenian Era.—This began 7 July 552, and was superseded by the Julian era about 1330. The year consisted of only 365 days.

Mohammedan Era, or Hegira.—This begins on 16 July 622. The conversion of the Mohammedan into Christian chronology causes more difficulty and confusion than arises with any of the other modes of reckoning. The Mohammedan year is purely lunar. It consists of 12 months, and each month commences with the appearance of the new moon. Hence their years have no correspondence with the recurrence of the seasons, and to know the period when a Mohammedan year begins it must be reckoned from the beginning of the era. In chronology, history, etc., they use months of 29 and 30 days alternately, making the year consist of 354 days. Eleven times in 30 years 1 day is added to the last month, making 355 days in the year. The mean length of the year is thus $354\frac{11}{30}$ days, of the month $29\frac{191}{360}$, differing from the true lunation by little more than three seconds, or less than a day in 2,260 years. As 33 Mohammedan years amount to only 6 days (including intercalary days and leap years) more than 32 of our years, by deducting one year from each 33 Mohammedan years, and adding 621½ years, the year of the Christian era will approximately be found. The Hegira is distinguished by the initials A. H.

Persian Era.—The era of Yezdegird III. began 16 July 632. The year consisted of 365 days. It was reformed in 1075 by the addition of a day whenever it was necessary to make the commencement of the year occur on the day of the sun's passing the same degree of the ecliptic. The months have each 30 days, with 5 or 6 days intercalated. This era is still used by the Parsees in India.

Indian Chronology.— The best-known eras computed by solar time are the Kaliyuga, which dates from 3101 years before Christ and the Salivahana from 77 A.D. Both are computed astronomically, losing one day in 60 years by our computation. The era of Vikramaditya, beginning 57 years B.C., is computed by lunar months, with intercalations made according to astronomical observation, and bringing the year up to 365 or 366 days. The Bengali year was formerly identical with the Hegira, but is now reckoned by solar computation.

Chinese Chronology.—The Chinese, like all the nations of northeast Asia, reckon their time by cycles of 60 years. Instead of numbering them as we do, they give a different name to every year in the cycle. The Chinese months are lunar, of 29 and 30 days each. Their years have ordinarily 12 months, but a 13th is added whenever there are two new moons while the sun is in one sign of the zodiac. This will occur 7 times in 19 years. The boasted knowledge of the Chinese in astronomy has not been sufficient to enable them to compute their time correctly. The first cycle, according to Roman Catholic missionaries, began February 2397 B.C. To find out the Chinese time, multiply the elapsed cycle by 60, and add the odd years; then if the time be before Christ subtract the sum from 2,398; but if after Christ, subtract 2,397 from it; the remainder will be the year required.

Primitive American Chronology.— The natives of America, previous to its discovery by Europeans, particularly the Peruvians and Mexicans, appear to have had a considerable acquaintance with astronomy and to have reckoned their time with great care. The Mexican year consisted of 365 days, composed of 18 months of 20 days, and 5 added days. At the end of a cycle of 52 years 12 and 13 days were added alternately, making the mean year very near the truth.

In geology, Epoch has now a very different meaning from that which it formerly had. Instead of corresponding to a period in the history of the earth, it answers to a period in the history of a particular locality. Epochs are determined by the occurrence of particular kinds of animal and vegetable life in a group of strata which are marked off by unconformity above and below; the rocks were deposited and the organisms lived in that locality between the two great geological changes, one of which preceded the earliest deposit of the particular group of rocks, while the other closed the series. The conformably sequent strata of this series belong to one epoch; but the dissimilar animals and plants which lived elsewhere at the same time were either not preserved at all in deposits or were entombed in deposits of a different kind. In the latter case the assemblage would represent an epoch for that particular locality. Thus the Old Red Sandstone and the Devonian strata, the former lacustrine, the latter marine, were probably identical in epoch as they were contiguous in area. If we imagine the floors of the German Ocean and the Australian seas, just as they now are, to be covered by thick deposits of strata, these strata would, judged by their fossil contents, belong to different epochs; but we know that they only belong to different zoological provinces. Natural groups of strata represent, therefore, the epochs during which the animals and plants they contain lived and died in a particular area, and where a closely similar assemblage is found in strata at a distant locality we have therefore proof that during an epoch of unknown length similar organisms flourished there; but the epoch may have been before, identical with, or later than that first studied.

Used in this sense epoch is a term of only local application, and the proof that though the assemblage of rocks may be a natural one for one locality, it is not so for a great area, is found in the fact that the unconformities which indicate great geological change do not occur at identical points everywhere. Thus the Silurian and Old Red formations are conformable in England, unconformable in Scotland, and unconformities in both series are differently placed in America.

In astronomy, epoch is the longitude which a planet has at any given moment of time. To predict this for any future period the longitude at a certain instant in the past must be known; that instant is termed the epoch of the planet.

Epode (Lat. epodus, Gr. ἐπῳδός, *epōdos*). In Greek choral poetry the term is used of an ode succeeding a strophe and antistrophe, or a series of strophes and antistrophes. The name was also given by grammarians to any poem the metrical unit of which is a distich consisting of a long, followed by a short verse. In this sense it was especially used of the iambic trimeter followed by the iambic dimeter, as in Epodes 1–10 of Horace.

Eponym, ĕp'ō-nĭm, a mythical personage created to account for the name of a tribe or people; thus Tros is the eponymous hero of Troy, Italus was assumed as ancestor of the Italians, etc.

Ep'ping, England, market town, in Essex, 17 miles from London, and in the midst of the forest to which it gives name. This ancient royal forest once a part of Waltham forest, and all much larger than at present, has an area of 5,600 acres, and presents some fine woodland scenery. It was secured to the nation by legislative enactment, and was opened by Queen Victoria in 1882 as a public recreation ground. The town consists of a single broad street on a ridge of hills. Pop. (1901) 3,789.

Epping Forest. See EPPING.

Eprouvette, ĕ-proo-vĕt', the name of an instrument for ascertaining the strength of gunpowder, or of comparing the strength of different kinds of gunpowder. The simplest kind is the hand eprouvette, in the form of a very short pistol. The barrel or powder-chamber is closed by a plate communicating with a strong spring. On the explosion the plate is driven back to a greater or less distance according to the strength of the powder, and is retained at the extreme distance by a ratchet-wheel.

Ep'som, England, town in the county of Surrey, 15 miles southwest of London. Epsom was formerly celebrated for a mineral spring, from the water of which the well-known Epsom salts were manufactured. A number of the sons of medical men are educated at the Royal Medical College, and adjoining the school is a home for aged physicians or their widows. The principal attraction Epsom can now boast of is the grand race-meeting held on the Downs, which is attended by hundreds of thousands of persons. The races begin on Tuesday, and continue to the end of the week preceding Whitsuntide; the Derby stakes are run for on Wednesday, which is the principal day, and the Oaks on Friday. There is also racing on two days earlier in the season; the town being otherwise characterized as "a dull little place for 50 weeks in the year." Epsom gives name to one of the parliamentary divisions of the county. Pop. (1901) 10,915.

Ep'som Salt, a hydrous sulphate of magnesium, having the formula $MgSO_4 + 7H_2O$. It occurs abundantly in nature, and takes its name from its occurrence, in dissolved form, in a mineral spring at Epsom, England. It may be prepared also from dolomite, by decomposing the mineral by the addition of sulphuric acid. Epsom salt, proper, is known to the mineralogist as epsomite, and more popularly as hair-salt, from the delicate fibrous efflorescent deposits in which it often occurs on the walls of mines, quarries, and caves. Epsomite crystallizes in the orthorhombic system, and large quantities of it are found in the limestone caves of Kentucky, Tennessee, and Indiana, mingled with earthy matter. In the Mammoth Cave it occurs in loose masses suggestive of snowballs, adhering to the roof and walls. An allied mineral known as kieserite, which has the composition $MgSO_4 + H_2O$, and occurs abundantly at Stassfurt, is largely used as a source of epsom salt. Magnesium sulphate is used as a fertilizer, as a raw material for the manufacture of the sulphates of sodium and potassium, and in sizing and dyeing cotton goods. The epsom salt is also extensively used as a purgative, in medicine.

Epu'lis. See MOUTH.

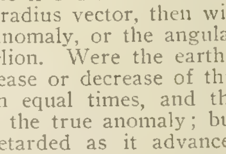
Epworth League, a society of young people of the Methodist Episcopal Church; formed 15 May 1889, in Cleveland, Ohio, by the union of five societies affiliated with the Methodist Church. It adopted as its motto: "Look up, Lift up," and its declared object is to "promote intelligent and loyal piety in the young members and friends of the Church; to aid them in the attainment of purity of heart and constant growth in grace, and to train them in works of mercy and help." The following pledge is required of its members: "I will earnestly seek for myself, and do what I can to help others to attain, the highest New Testament standard of experience and life. I will abstain from all forms of worldly amusement forbidden by the discipline of the Methodist Episcopal Church, and I will attend, as far as possible, the religious meetings of the chapter and the Church, and take some active part in them." The league is governed by a board of control, partly appointed by the bishops and partly elected by the General Conference districts, one member for each district; represented by an executive cabinet, consisting of a president, four vice-presidents, general secretary, general treasurer, and a German assistant treasurer. The league has grown rapidly, extending to foreign lands, and there are chapters in India, Mexico, South America, Italy, Norway, Sweden, Denmark, Finland, China, Japan, and Hawaii. On 1 Oct. 1902, there were in the league 29,600 chapters and 2,000,000 members. Its official organ is the 'Epworth Herald,' published in Chicago.

Equal Rights Party, in 1835. See LOCOFOCOS.

Equal Rights Party, in 1884. Belva Lockwood nominated herself for the presidency, on a platform of woman suffrage; and gave her voters this title.

Equality, a sociological work by Edward Bellamy (1897). Consult 'Equality'; 'Looking Backward.'

Equation, a term based on the idea of equality, in general use throughout the various branches of calculus. (1) In mathematics it is the statement in algebraic expressions of the equality of two or other mathematical expressions. The assertion of equality is made by writing the sign = (read "is equal to" or "equals") between the expressions. Thus: $5x + 7 = 32$, and $ax^2 + bx + c = O$, are equations, each of which indicates the equality of the quantity written on the left of the sign (=) to that written on the right of the sign. Usually the object of writing down an algebraic equation is to express in symbols known relations between given and unknown quantities, so that by algebraic processes the latter may be determined in terms of the former. (See ALGEBRA.) (2) In astronomy is the correction by addition to or subtraction from the mean motion of any heavenly body, in order to determine its true place at any given time. The mutual attraction among the planets renders each one capable of producing a perturbation in the orbits of all the others. An equation is required for every such perturbation before it is possible to calculate accurately the course of the planet. Thus we have the equation of the centre, a quantity to be added to or subtracted from the anomaly, in order to determine the true position of a heavenly body. For instance, let the curve E C F represent the earth's orbit (which is an ellipse), E F the line of the apsides, and A the position of the sun. When the earth is in any position as C, the line A C drawn from the sun to the planet is the radius vector, then will the angle C A F be the anomaly, or the angular distance from the perihelion. Were the earth's motion uniform the increase or decrease of this angle would be equal in equal times, and the mean anomaly would be the true anomaly; but the earth's motion is retarded as it advances from F to C, is slowest at E, and is accelerated from that point, the aphelion, through the other half of its orbit till it arrives at F, the perihelion. The quantity to be added to the mean angular motion, during one portion of the orbit, or subtracted from it in the other, in order to find the true anomaly, is called the equation of the centre. (3) In chemistry, is a collection of symbols to denote that two or more definite bodies — simple or compound — have been brought within



the sphere of chemical action, that a reaction has taken place, and that new bodies are produced. It is called an equation because the total weight of the substances concerned remains the same. See CHEMISTRY.

Equation, Personal, an important correction that must be considered in connection with refined measurements in astronomy and physics, and which originates in the fact that no two observers agree precisely as to the instant at which a phenomenon occurs, nor as to the setting of a micrometer-wire so as to bisect a division mark on a scale. Differences of this sort are exceedingly irregular among inexperienced observers, but among the more experienced ones the regularity, while not absolute, is strongly marked. In some kinds of work the personal equation of the observer can be eliminated by the method in which the observations are made. Thus, in the determination of differences of longitude by telegraphic methods, it is usual to eliminate the effect of personal error from the final result by having the observers change places when the work is half done; so that if the difference of longitude as determined by the first half of the work was too large, that determined during the second half will be too small by an equal amount, and the effect of personal equation will disappear from the final mean. In other cases it is impossible to eliminate the effects of personal error in any such way, and in these cases the attempt is often made to determine the magnitude of the personal equation, and apply the proper correction to the results as directly observed. Thus Otto Struve, in connection with his measurements on double stars, had artificial double stars constructed, upon which he made regular observations for the purpose of studying his personal equation in such work, and he applied, to his results for the genuine stars, a series of corrections deduced in this way. When the thing to be measured is an interval of some kind, the personal equation can usually be neglected, provided the same observer makes all the measures. For example, in determining the length of a bar, the reading of the micrometers will be in error (so far as the personal equation is concerned) by the same amount at both ends of the bar, and hence the difference of these readings; or, in other words, the observed length of the bar will be independent of the observer's personal equation.

Equations, Differential. — 1. *Introduction.*— The invention of the calculus, made necessary by the demands of natural science, was followed immediately by the most brilliant applications. The names of Newton, Leibnitz, Euler, Lagrange, and Laplace are attached to the principal discoveries of this period, whose importance from a scientific and philosophical point of view can hardly be overestimated. A simple example will suffice to explain the ruling idea of this epoch. From the observations of Tycho Brahe, Kepler had obtained the laws of planetary motion still known by his name. Newton had shown that Kepler's laws were but a consequence of the law of universal gravitation, which assumes that every particle in the universe acts upon every other according to a definite law. The effect of Newton's law upon a system of moving bodies can be formulated in mathematical symbols without any difficulty. This formulation gives rise to a system of equations involving the coordinates of the moving bodies and their accelerations, *i.e.*, the second derivatives of these coordinates with respect to the time. The problem of expressing the coordinates as functions of the time, *i.e.*, the problem of integrating this system of differential equations, was solved by Newton for the case of two mutually attracting bodies, and its solution is given precisely by Kepler's laws. Newton himself and his successors, especially Laplace and Lagrange, studied the further consequences of the law of gravitation as applied to the solar system. The accord between theory and observation became closer and closer, so that it was reasonable to suppose that the true law of nature had been found. Gradually other branches of physical science were treated in a similar way. In all cases, the fundamental laws being assumed, the mathematical formulation of the problems led to the question of integrating differential equations. It should be noted that, although in some cases this method of arriving at the formulation of the physical problems has now been abandoned, differential equations are now, more than ever, used as the expressions for the fundamental phenomena in physical science. For the applications of mathematics there is no field so important as the theory of differential equations. That the whole world is a mathematical problem was the point of view gained by Laplace, an insight gained in a different way also by Leibnitz and Spinoza. But the mathematician is more specific; we learn from him that this world-problem belongs to the domain of the theory of differential equations. Even if the details of the picture have changed, the formulation of this general idea is one of the positive achievements of the philosophical thought of the eighteenth century.

Ordinary Differential Equations. Elementary Theory.—Let y be determined as a function of x by means of an equation,

$$\phi(x, y, a) = 0, \tag{1}$$

which involves an arbitrary constant a. If x and y be interpreted as the coordinates of a point in the plane, equation (1) represents a family of curves, one curve for each value of a. By differentiation we find, from (1),

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0. \tag{2}$$

Between these two equations a may be eliminated; the result will be an equation of the form

$$f\left(x, y, \frac{dy}{dx}\right) = 0, \tag{3}$$

free from a. Equation (3) is a *differential equation.* Since it does not contain the constant a it gives the expression of a property which is common to all of the curves of the family (1). The main object of the theory of differential equations is to invert the process which we have just carried out, *i.e.*, the equation (3) being given, the equation (1) involving an arbitrary constant, from which (3) may be derived by differentiation, is to be found. This process is known as the *integration of the differential equation.*

In general let there be given an equation of the form

$$f\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \ldots \frac{d^ny}{dx^n}\right) = 0,$$

between x, the function y of x and its derivatives up to the nth order; it is called an *ordinary differential equation of the nth order*. The adjective *ordinary* implies that y is considered as a function of only *one* independent variable x. Under certain restrictions as to the continuity of the function f (a question to which we shall recur later), it may be shown that there exists a function y of x and of n arbitrary constants which satisfies the differential equation; it is known as the *general integral of the differential equation;* the determination of this function is the object of the theory of differential equations. The equation is then said to have been integrated.

The simplest case of such a differential equation presented itself in the problem of finding the area included between a curve $y = f(x)$, the x-axis, and two ordinates erected for $x = a$ and $x = x$. The differential equation satisfied by the area z considered as function of x is

$$\frac{dz}{dx} = f(x),$$

and the area itself becomes

$$z = \int_a^x f(x)dx.$$

This simple case served as a model for the earlier investigators in this field. Confining ourselves for the moment to equations of the first order, it may be possible to reduce such an equation to the form

$$\frac{dx}{R(x)} + \frac{dy}{S(y)} = 0,$$

where $R(x)$ is a function of x, and $S(y)$ a function of y alone. The variables are then said to be *separated*, and we may write

$$\int \frac{dx}{R(x)} + \int \frac{dy}{R(y)} = c,$$

where c is an arbitrary constant. Owing to the fact, which has just been mentioned, that the problem of areas is solved by the computation of an integral of the form $\int_a^x f(x)dx$, such an integration is known as a *quadrature*. If the variables can be separated, the differential equation may, therefore, be integrated by quadratures.

The earlier analysts believed that any differential equation could be integrated by the elementary functions then in use, and by quadratures. This we now know not to be the case, just as we know, since the days of Abel, that all algebraic equations cannot be solved by the mere extraction of roots. (See ALGEBRA; THEORY OF EQUATIONS; GALOIS' THEORY.) Moreover, even if the reduction to quadratures can be effected, such a reduction is, properly speaking, the beginning and not the end of the investigation. For it does not suffice to give a formal indication of the relation between x and y; this relation must be thoroughly understood in its essential properties before the integration can be said to have been accomplished. Nevertheless the consideration of the simpler cases, in which integration by means of elementary functions or by quadratures is possible, constitutes a first important chapter of the theory of differential equations. We may characterize this chapter as the *elementary* theory of differential equations.

Elementary Theory of Differential Equations.—We have already referred to the case in which the variables are separated. In many cases a simple transformation will accomplish the separation. Consider, for example, the equation

$$(4) \qquad \frac{dy}{dx} + Py = 0,$$

where P is a function of x only. We may write

$$\frac{dy}{y} + Pdx = 0,$$

whence

$$\log y + \int Pdx = \log c,$$

or

$$(5) \qquad y = ce^{-\int Pdx}.$$

This example will be useful in enabling us to treat, at once, a more general equation; we shall do so, moreover, by making use of a method frequently employed, and especially important in the applications to theoretical astronomy, the method of *variation of constants*. We consider the equation

$$(6) \qquad \frac{dy}{dx} + Py = Q,$$

where P and Q are functions of x only. This equation is the most general linear differential equation of the first order, a linear equation being one which contains y and its derivatives in no higher than the first power. Equation (6) differs from (4) only in having Q in the right member in place of zero. The expression (5) will certainly not satisfy (6) since it satisfies (4). Clearly, however, it must be possible to satisfy (6) by an expression of the form analogous to (5), viz.,

$$(7) \qquad y = ue^{-\int Pdx},$$

where u is a properly chosen function of x instead of being a constant. Moreover, as we shall see, we can actually determine the function u by quadratures. In fact, we find from (7)

$$\frac{dy}{dx} = \left(\frac{du}{dx} - Pu\right)e^{-\int Pdx},$$

which gives, on substitution into (6)

$$\frac{du}{dx} = Qe^{\int Pdx},$$

so that we shall have

$$(8) \qquad y = e^{-\int Pdx}\left[C + \int Qe^{\int Pdx}dx\right],$$

as the general integral of (6). This formula was found by Jacob Bernoulli, who also showed that the equation

$$(9) \qquad \frac{dy}{dx} + Py = Qy^{-m+1}$$

could be reduced to (6) by putting $u = y^m$.

The *homogeneous* equations of the form

$$(10)\qquad \frac{dy}{dx}=\phi\left(\frac{y}{x}\right),$$

where $\phi\left(\frac{y}{x}\right)$ depends only upon the ratio of y to x, may also be solved by quadratures. In fact, if we put $y=vx$, the equation becomes

$$\frac{dx}{x}+\frac{dv}{v-\phi(v)}=0,$$

whence

$$(11)\qquad \log x+\int\frac{dv}{v-\phi(v)}=c.$$

Euler's method of the *integrating factor* is sometimes useful. It rests upon the following considerations. Let $\phi(x, y)=\text{const.}$ be the equation of any integral curve of the equation

$$(12)\qquad P(x, y)dx+Q(x, y)dy=0.$$

We shall have, by differentiation from $\phi(x, y)=\text{const.}$,

$$\frac{\partial\phi}{\partial x}dx+\frac{\partial\phi}{\partial y}dy=0,$$

an equation which must have the same significance as (12). We must, therefore, have

$$(13)\qquad \mu P(x, y)=\frac{\partial\phi}{\partial x},\quad \mu Q(x, y)=\frac{\partial\phi}{\partial y},$$

if μ is a properly chosen function of x and y. If μ is known, the determination of ϕ by quadratures can be immediately accomplished on account of the two equations (13). For this reason μ is called an integrating factor. Equations (13) show that μ must satisfy the partial differential equation

$$(14)\qquad \frac{\partial(\mu P)}{\partial y}-\frac{\partial(\mu Q)}{\partial x}=0.$$

In general, the determination of an integrating factor is just as difficult as the integration of the equation. But Euler succeeded in finding a number of equations with known integrating factors. Herein lies the value of the method.

By means of these various methods there was obtained in the course of time a considerable number of equations which could be integrated by quadratures. Lie showed that this rather scrappy theory could be understood as the consequence of a single principle. This we shall now proceed to explain, making use of geometric images for the sake of clearness as well as brevity.

The equations

$$x_1=\phi(x, y),\quad y_1=\psi(x, y),$$

are said to constitute a *transformation* of the point (x, y) into the point (x_1, y_1) if they can be solved for x_1 and y_1.

These equations may contain a certain number of arbitrary constants $a_1, \ldots a_r$; they are then said to constitute an r-parameter family of transformations. Let us consider the simplest case of a one-parameter family which we may write

$$(15)\qquad x_1=\phi(x, y;\ a),\quad y_1=\psi(x, y;\ a).$$

If the parameter a has a definite value, this transformation converts every point (x, y) into a definite other point (x_1, y_1). Let us transform this new point (x_1, y_1) by equations of the *same* form, but with a different parameter b, into a third point (x_2, y_2), so that we shall have

$$(16)\qquad x_2=\phi(x_1, y_1;\ b),\quad y_2=\psi(x_1, y_1;\ b).$$

In general, if we eliminate x_1, y_1 between (15) and (16) we shall find x_2 and y_2 as functions of x, y, a, and b. It *may* happen that these functions assume the form

$$(17)\qquad x_2=\phi(x, y;\ c),\quad y_2=\psi(x, y;\ c)$$

where c is a function of a and b, and where the functions ϕ and ψ are the *same* as in (15) and (16). If this is the case, the transformations (15) are said to form a one-parameter *group*. The one-parameter family of transformations (15) then has the property that the transformation, obtained by combining any two of its transformations, is itself a member of the family. It is for this reason that the family is then called a *group*. (See GROUPS, THEORY OF.) It is obvious how this definition may be extended to cover r-parameter groups.

The one-parameter group (15) will contain, in general, the identical transformation; *i.e.*, for a certain value a_0 of a (15) will reduce to $x_1=x$, $y_1=y$. If now we denote by ∂t an infinitesimal, and put in (15) $a=a_0+c\partial t$, we shall find a transformation which transforms (x, y) into a point (x_1, y_1) such that the differences $x_1-x=\partial x$ and $y_1-y=\partial y$ will be infinitesimals of the order of ∂t. This will be true unless certain exceptional cases arise which we need not, at present, discuss. From every one-parameter group we may deduce in this way an *infinitesimal transformation*, and Lie has shown that conversely every infinitesimal transformation determines a one-parameter group. There is a similar connection between an r-parameter group and a corresponding set of r infinitesimal transformations, between which certain relations must then be satisfied.

A one-parameter group always has an *invariant*; *i.e.*, there exists a function $\Omega(x, y)$ such that, for all transformations (15) of the group, $\Omega(x_1, y_1)=\Omega(x, y)$. Such a function is said to *admit* the one-parameter group of transformations. It admits, in particular, the infinitesimal transformation of the group. Similarly, a differential equation may admit one or more infinitesimal transformations. Lie has shown that in the cases in which the variables may be separated, *i.e.*, in which integration by quadratures is possible, it is possible to write down infinitesimal transformations which leave the equations invariant. He has developed a general theory showing what advantage is gained for the integration of a differential equation by the knowledge that it admits one or more infinitesimal transformations. Let us remark, explicitly, that this theory is not confined to equations of the first order nor even to ordinary differential equations.

Before passing to the consideration of the elementary theory of equations of higher order, we proceed to explain the important notion of *singular solution*. Geometrically, an equation of the first order $\frac{dy}{dx}=\phi(x, y)$ determines the tangent of an integral curve at every point of the plane. If we start from any point P, the tangent of the integral curve passing through that point is completely determined. We follow the direction thus indicated for an infinitesimal distance to the point $(x+\partial x, y+\partial y)$. At this point the tangent is again given by the differential equation, etc. We obtain in this way, synthetically, the family of integral curves, say $F(x, y, c)=0$. Any one of these curves is obtained by giving a definite value to the constant of integration c. The envelope of this system of curves, however, will also be a solution of the differential equation. For it will also be a curve whose tangent satisfies the requirements of the equation. But, in general, the envelope will not be itself a member of the family of curves, *i.e.*, it will not be possible to find its equation by giving a special value to c. The envelope is then said to give a singular solution of the equation. If it exists, it may be found without any integration, that is to say, without a knowledge of the general integral of the differential equation.

The most important case of a differential equation of a higher order, which may be treated by elementary methods, is that of the linear homogeneous differential equation of the nth order with constant coefficients. A linear homogeneous differential equation of the nth order has the form

$$(18)\qquad \frac{d^n y}{dx^n}+p_1\frac{d^{n-1}y}{dx^{n-1}}+\ .\ .\ .\ +p_n y=0.$$

If $y_1, y_2, \ldots, y_n$ are particular solutions of the equation, $y=c_1y_1+c_2y_2+\ .\ .\ .\ +c_ny_n$, where $c_1, \ldots c_n$ are constants, is also a solution. Moreover, if $y_1, \ldots y_n$ are linearly independent, *i.e.*, if they satisfy no relation of the form $\gamma_1y_1+\gamma_2y_2+\ .\ .\ .+\gamma_ny_n=0$, where $\gamma_1, \ldots \gamma_n$ are constants, the above expression for y is the general solution. $y_1, \ldots y_n$ are then said to constitute a *fundamental system* of solutions. In the case that $p_1, \ldots p_n$ are constants a fundamental system may be easily obtained. In fact we find that $y=e^{\rho x}$ is a solution of (18) if ρ is a root of the equation

$$\rho^n+p_1\rho^{n-1}+\ .\ .\ .\ +p_{n-1}\rho+p_n=0.$$

Moreover, if $\rho_1, \ldots \rho_n$ are the roots, supposed distinct, of this equation, $e^{\rho_1x}, e^{\rho_2x}, \ldots e^{\rho_nx}$ actually form a fundamental system. If λ roots, say $\rho_1, \rho_2, \ldots \rho_\lambda$, coincide, the λ identical functions $e^{\rho_1x}, \ldots e^{\rho_\lambda x}$ are replaced by $e^{\rho_1x}, xe^{\rho_1x}, x^2e^{\rho_1x}, \ldots x^{\lambda-1}e^{\rho_1x}$.

Total Differential Equations.—In the case of an equation between two variables which we have considered so far, one important distinction, which we shall now have to make, has not been necessary. If $P(x, y)dx+Q(x, y)dy=0$ is such an equation, it is always possible to find a single function $\phi(x, y)$ such that $\phi(x, y)=$const. shall represent the general integral. Either the expression $Pdx+Qdy$ is the complete differential of $\phi(x, y)$ so that $P=\frac{\partial\phi}{\partial x}$ and $Q=\frac{\partial\phi}{\partial y}$, or else upon multiplication with Euler's integrating factor $\mu(Pdx+Qdy)$ becomes such a complete differential. This is not the case when there are more than two variables. Consider such an equation in three variables,

$$(19)\qquad Pdx+Qdy+Rdz=0,$$

where P, Q, R are functions of x, y, and z. For the sake of symmetry assume that x, y, z are regarded as functions of a fourth variable t. The problem before us is to find all sets of functions x, y, z of t which will satisfy (19). It *may* happen that the left member of (19) becomes a complete differential upon multiplication with a function μ of x, y, z, so that

$$\mu P=\frac{\partial\phi}{\partial x},\quad \mu Q=\frac{\partial\phi}{\partial y},\quad \mu R=\frac{\partial\phi}{\partial z}.$$

The elimination of μ from these three equations shows that this can be the case only if P, Q, R satisfy the so-called integrability condition:

$$(20)\quad P\left(\frac{\partial Q}{\partial z}-\frac{\partial R}{\partial y}\right)+Q\left(\frac{\partial R}{\partial x}-\frac{\partial P}{\partial z}\right)+R\left(\frac{\partial P}{\partial y}-\frac{\partial Q}{\partial x}\right)=0.$$

Moreover it may be shown that if P, Q, R satisfy this condition, there exists a function $\phi(x, y, z)$ and an integrating factor $\mu(x, y, z)$ such that

$$\mu(Pdx+Qdy+Rdz)=d\phi,$$

so that integration of (19) will give the result $\phi(x, y, z)=$const. But if (20) is not satisfied, no integration of (19) in this sense is possible. The reason for this distinction as well as the discussion of the non-integrable case will be clearly understood if we make use of a geometric interpretation. Let x, y, z be Cartesian coördinates of a point in space. If x, y, z are known as functions of t, there will be determined a certain space-curve. It is our problem to determine such space-curves

$$x=f(t),\quad y=g(t),\quad z=h(t)$$

as satisfy (19). Through every point (x_0, y_0, z_0) of space there may be drawn an infinity of such curves. The tangents of all of these curves which pass through the point (x_0, y_0, z_0) form a plane pencil with (x_0, y_0, z_0) as vertex and the plane

$$P(x_0, y_0, z_0)(x-x_0)+Q(x_0, y_0, z_0)(y-y_0)\\ +R(x_0, y_0, z_0)(z-z_0)=0$$

as plane. Thus there is for every point P a plane p containing P, to which all of the integral curves of (19) which pass through P must be tangent. We may now imagine an integral curve of (19) constructed as follows: Start from a given point P and construct the corresponding plane p. We go from P to a point Q infinitesimally close to P but otherwise arbitrarily situated in the plane p. At Q we construct the plane q corresponding to it, and in this plane we pick out a point R infinitesimally close to Q. Proceeding in this way we gradually build up an integral curve. It *may* happen that *all* of the integral curves of (19) which pass through the point P are situated upon a certain surface S. If this is the case for all points P, the integrability condition is satisfied; there exists a single infinity of surfaces $\phi(x, y, z)=c$, such that an arbitrary curve upon each of these surfaces satisfies the differential equation. In general, however, such a family of surfaces does not exist. We may then integrate (19) as follows: Take an *arbitrary* surface $\psi(x, y, z)=0$. Let P be any point upon it. Let p be the plane of the pencil of directions which the differential equation assigns to P, and let p' be the plane tangent to the surface $\psi(x, y, z)=0$ at P. The intersection t of p and p' will be at the same time tangent to an integral curve of (19) and tangent to the surface $\psi=0$. From P we go along t to a point Q infinitesimally close to P and there repeat this process. We may build up in this way all of the integral curves of (19) which are situated upon an arbitrary surface. Upon every arbitrary surface there will be a single infinity of such curves. Analytically this process may be carried out as follows: From $\psi=0$ we find

$$\frac{\partial\psi}{\partial x}dx+\frac{\partial\psi}{\partial y}dy+\frac{\partial\psi}{dz}dz=0.$$

From this equation and $\psi=0$, dz and z may be expressed in terms of x, y, dx, and y. Substitution of these values into (19) gives rise to an equation of the form

$$M(x, y)dx+N(x, y)dy=0,$$

which may be integrated in the form $\phi(x, y)=c$. This latter equation together with $\psi(x, y, z)=0$ gives the required solution. By giving all possible forms to the functions ψ all possible solutions will be obtained.

Similar considerations are necessary in the general case of n variables. The first considerable contribution to this theory is due to Pfaff. For this reason such an equation is known as a *Pfaffian equation*, and the problem of its integration as *Pfaff's problem*. The problem leads to a system of no more than n integral equations when the number of variables is $2n$ or $2n-1$. If the equations are of higher than the first degree in the differentials, Lie speaks of them as *Monge equations*. Many problems of differential geometry, especially in relation to the theory of complexes, are connected with Pfaffian and Monge equations.

Partial Differential Equations.—Frequently functions of several variables are defined by relations between those functions and their partial derivatives. Such equations are called partial differential equations. For the sake of simplicity we will confine ourselves to the case of a single unknown function, and for the most part to the case of two independent variables. As in the case of ordinary differential equations, it will be instructive to see first how such equations may arise as the result of elimination of arbitrary elements from equations which do not involve the derivatives. Let z be given as a function of x, y and of the two arbitrary constants a, b by the equation

$$f(x, y, z;\ a, b)=0. \tag{21}$$

Let p, q represent $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ respectively. Then differentiation will give

$$\frac{\partial f}{\partial z}p+\frac{\partial f}{\partial x}=0,\quad \frac{\partial f}{\partial z}q+\frac{\partial f}{\partial y}=0. \tag{22}$$

Between the three equations (21) and (22) a and b may be eliminated. Let

$$F(p, q;\ x, y, z)=0 \tag{23}$$

be the result of this elimination. It is the partial differential equation which corresponds to (21); (21) is called the *complete* integral of (23).

But a and b in (21) may be functions of x, y and still the result of the elimination may be the same equation (23). In fact we find from (21), assuming that a and b are functions of x and y,

$$\frac{\partial f}{\partial z}p+\frac{\partial f}{\partial x}+\frac{\partial f}{\partial a}\frac{\partial a}{\partial x}+\frac{\partial f}{\partial b}\frac{\partial b}{\partial x}=0,$$

$$\frac{\partial f}{\partial z}q+\frac{\partial f}{\partial y}+\frac{\partial f}{\partial a}\frac{\partial a}{\partial y}+\frac{\partial f}{\partial b}\frac{\partial b}{\partial y}=0,$$

which equations will reduce to (22), and therefore give rise to the same equation (23), if

$$\frac{\partial f}{\partial a}\frac{\partial a}{\partial x}+\frac{\partial f}{\partial b}\frac{\partial b}{\partial x}=0,\quad \frac{\partial f}{\partial a}\frac{\partial a}{\partial y}+\frac{\partial f}{\partial b}\frac{\partial b}{\partial y}=0. \tag{24}$$

Let the determinant of these equations be denoted by Δ, so that

$$\frac{\partial a}{\partial x}\frac{\partial b}{\partial y}-\frac{\partial a}{\partial y}\frac{\partial b}{\partial x}=\Delta;$$

then we may write, in place of (24), the equivalent equations

$$\Delta\frac{\partial f}{\partial a}=0,\quad \Delta\frac{\partial f}{\partial b}=0. \tag{24a}$$

If $\Delta\neq 0$, we must therefore have

$$\frac{\partial f}{\partial a}=0,\quad \frac{\partial f}{\partial b}=0.$$

From these equations a and b may be obtained as functions of x and y; if these values are substituted in (21), a function z of x and y is obtained, independent of any arbitrary constants, but still a solution of the partial differential equation (23). This solution is called a *singular* integral of (23). It may or may not be a special case of the complete integral.

Equations (24a) are also satisfied if $\Delta=0$, *i.e.*, if

$$b=\phi(a), \tag{25}$$

where $\phi(a)$ denotes an arbitrary function of a. If we multiply the left members of (24) by dx and dy respectively, and add, we find

$$\frac{\partial f}{\partial a}da+\frac{\partial f}{\partial b}db=0,$$

whence, since $db=\phi'(a)da$,

$$\frac{\partial f}{\partial a}+\frac{\partial f}{\partial b}\phi'(a)=0. \tag{26}$$

If we eliminate a and b from the equations (21), (25), and (26), we find z as a function of x and y, the expression of which depends upon the arbitrary function ϕ. Moreover this function z will again be a solution of (23). It is known as the *general integral*, and involves an arbitrary function. It may be shown that every integral of such a partial differential equation belongs to one of these three classes.

Geometrical interpretation will again render the matter perfectly clear. Let x, y, z be coordinates of a point in space; (21) will represent a two-parameter family of surfaces, or, as we may say, a family of ∞^2 surfaces. The equation of the plane tangent to one of these surfaces at a point (x, y, z) will be

$$\zeta-z=p(\xi-x)+q(\eta-y).$$

For a fixed value of x, y, z, (23) gives therefore an infinity of planes through that point (enveloping a cone); any integral surface of (21), which passes through that point, must have one of these planes as its tangent plane. In other words, the differential equation determines a certain cone corresponding to every point of space, and with this point as vertex;

an integral surface must be tangent at each of its points to the corresponding cone. Now let a complete solution of the equation be given, so that we know a family of ∞^2 surfaces each of which fulfills the requirements of the problem. If we put $b=\phi(a)$, where $\phi(a)$ is any function of a, we obtain a one-parameter family of surfaces included among the ∞^2 surfaces just mentioned. The envelope of this one-parameter family is given by the general integral. The singular integral is the envelope of all of the ∞^2 surfaces of the complete integrals, provided that such an envelope exists.

Since the surface represented by the general integral is the envelope of a single infinity of surfaces represented by the complete integral, each of these latter surfaces will touch the former along a certain curve; such a curve is known as a *characteristic*. If the partial differential equation is not linear in $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$, there are ∞^3 characteristics. A linear equation has only ∞^2 characteristics. The integral surfaces may be looked upon as generated by characteristics, and the usual method of integrating the partial differential equation consists in setting up a system of ordinary differential equations which determines the characteristics.

The Points of View in the Higher Theory.—In speaking of ordinary differential equations, we have already mentioned the fact that the point of view of the elementary theory is inadequate even in those cases in which the reduction to quadratures is possible. Given, for example, the equation

$$\left(\frac{dy}{dx}\right)^2=(1-y^2)(1-k^2y^2),$$

which may be reduced to a quadrature,

$$x=\int\frac{dy}{\sqrt{(1-y^2)(1-k^2y^2)}}.$$

The reduction of the equation to this form is a mere formal process which, in itself, teaches us nothing. We shall have to ask ourselves the following questions: to what extent does a given differential equation define a function y of x? what are the characteristic properties of this function? what analytical processes involving known functions, infinite series, products, etc., will serve for the computation of the values of the function for all of the values of its argument? In the case of the above differential equations these questions have been completely answered by the creation of the theory of elliptic functions by Abel and Jacobi. In general it is to be expected that every differential equation defines a transcendental function; it is the theory of these transcendentals which constitutes properly the most important portion of the theory of differential equations.

In order fully to understand the properties of functions it has been found necessary to look upon the variable as being capable of assuming not only all real but also all complex values. In the hands of Cauchy, Riemann, Weierstrass there has grown up in this way the *theory of functions of a complex variable* (q.v.). This theory serves as a base for our further discussions. We shall, however, confine ourselves to a few of the simplest cases, merely indicating the general point of view.

Let

$$\frac{dy}{dx}=f(x, y)$$

be the given differential equation. Let $f(x, y)$ be analytic in the vicinity of (x_0, y_0), *i.e.*, let it be possible to develop $f(x, y)$ into a series proceeding according to positive integral powers of $x-x_0$ and $y-y_0$. Then, as was first proved by Cauchy, there exists a function y of x which may be developed according to positive integral powers of $x-x_0$, which reduces to $y=y_0$ for $x=x_0$, and which satisfies the differential equation. This theorem, which may be easily generalized to apply to equations of higher order, or to systems of equations of the first order, is generally known as the fundamental theorem of the theory of differential equations. It proves the existence of analytic functions which are uniquely defined as solutions of analytic differential equations and which satisfy the subsidiary condition of reducing to given values for a given value of the argument. The theorem may be proved by the so-called «Calcul des limites.» This consists in finding a series which formally satisfies the differential equation and reduces to y_0 for $x=x_0$; its convergence is then demonstrated by comparing it term for term with a corresponding series, which is formed in the same way from another differential equation, and which is known to be convergent. The exact circle of convergence cannot, however be generally stated. A great many papers have been written on questions which easily suggest themselves in connection with this theorem. If the function $f(x, y)$ is not developable in the given form; if, for example, its development contains negative or fractional exponents, how far are its solutions determined and what is the form of their developments? Besides the analytic solutions whose existence Cauchy has demonstrated, are there other non-analytic solutions? The first investigations of these equations are due to Briot and Bouquet. They have since been completed by a great many authors.

Cauchy's existence theorem can be made more precise in the case of *linear* differential equations. Let

$$\frac{d^ny}{dx^n}+p_1\frac{d^{n-1}y}{dx^{n-1}}+\ldots+p_ny=0 \tag{27}$$

be a homogeneous, linear differential equation of the nth order. In the vicinity of $x=x_0$ let the coefficients p_κ be expressible as power-series, proceeding according to positive integral powers of $x-x_0$, and convergent for all values of x for which $|x-x_0|<r$, where r is a real positive quantity, *i.e.*, for all points of the plane of the complex variable which are within a circle of radius r and of center x_0. Then, there exists a function y of x, expressible as a power series convergent in the *same* domain, which satisfies the differential equation, and which, together with its first $n-1$ derivatives, assumes arbitrarily prescribed values for $x=x_0$.

The proof of this theorem, due to Fuchs, is also based on the «calcul des limites.» The important point is the fact that the true radius of convergence of the series is determined by inspection from the differential equation itself. The existence of a fundamental system of solutions expressible by power-series follows at once.

Let $y_1, \ldots y_n$ be the members of such a fundamental system. Let $a_1, \ldots a_m$ be the singular points (poles) of the coefficients $p_1, \ldots p_n$ which we shall assume to be rational functions of x. Let $y_1, \ldots y_n$ be continued analytically along a path passing, in the positive direction, around one of these singular points a, and let $\bar{y}_1, \ldots \bar{y}_n$ be the new branches of the functions $y_1, \ldots y_n$ which are thus defined by power-series in the vicinity of $x = x_0$ after this process. We must have

(28) $\bar{y}_\kappa = \alpha_{\kappa 1} y_1 + \alpha_{\kappa 2} y_2 + \ldots + \alpha_{\kappa n} y_n$, $(\kappa = 1, 2, \ldots n)$,

where $\alpha_{\kappa i}$ are constants, since $\bar{y}_1, \ldots \bar{y}_n$ must constitute again a system of solutions (moreover a fundamental system). A new fundamental system may be chosen in the following manner. Put

$$z = c_1 y_1 + c_2 y_2 + \ldots + c_n y_n,$$

where $c_1, \ldots c_n$ are constant coefficients. After the continuation around a, z will be changed into

$$\bar{z} = c_1(\alpha_{11} y_1 + \ldots + \alpha_{1n} y_n) + \ldots + c_n(\alpha_{n1} y_1 + \ldots + \alpha_{nn} y_n).$$

This will be equal to ωz, where ω is a constant, if

$$(29) \quad \begin{aligned} c_1(\alpha_{11} - \omega) + c_2\alpha_{21} + \ldots + c_n\alpha_{n1} &= 0, \\ c_1\alpha_{12} + c_2(\alpha_{22} - \omega) + \ldots + c_n\alpha_{n2} &= 0, \\ \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot & \\ c_1\alpha_{1n} + c_2\alpha_{2n} + \ldots + c_n(\alpha_{nn} - \omega) &= 0, \end{aligned}$$

whence

$$(30) \quad F(\omega) = \begin{vmatrix} \alpha_{11} - \omega, & \alpha_{21}, & \ldots & \alpha_{n1} \\ \alpha_{12}, & \alpha_{22} - \omega, & \ldots & \alpha_{n2} \\ \cdot & \cdot & \cdot & \cdot \\ \alpha_{1n}, & \alpha_{2n}, & \ldots & \alpha_{nn} - \omega \end{vmatrix} = 0.$$

If ω_1 is a root of (30), and the ratios of $c_1, \ldots c_n$ are determined from (29) after ω has been put equal to ω_1, we shall therefore find a solution z_1 of (27) which changes into $\omega_1 z_1$ when the variable x describes a closed path around the singular point considered. If the equation $F(\omega) = 0$ has n distinct roots, we shall find n such solutions, and we may write

$$(31) \qquad \bar{z}_i = \omega_i z_i, \qquad (i = 1, 2, \ldots n)$$

in place of (28). Moreover these n solutions $z_1, \ldots z_n$ will constitute a fundamental system. We shall not attempt to discuss the case of coincident roots of the equation (30), which is known as the *fundamental* or *characteristic* equation.

Now the function

$$(x-a)^{r_i} = e^{r_i \log (x-a)}, \quad r_i = \frac{1}{2\pi i} \log \omega_i$$

has precisely the same property. Therefore the quotient $\dfrac{z_i}{(x-a)^{r_i}}$ is a function uniform in the vicinity of $x = a$, and therefore expressible by a so-called Laurent series proceeding according to positive and negative but integral powers of $x - a$. Let $\phi_i(x)$ be such series; then we have

$$(32) \quad z_i = (x-a)^{r_i} \phi_i(x), \quad (i = 1, 2, \ldots n).$$

The Laurent series will be convergent for all points, excepting a itself, of the circle which has a as center and which reaches up to the nearest singular point of the differential equation. The main questions to solve are: 1st. Determine the exponents r_i; 2d. Find the coefficients of the Laurent series ϕ_i. These questions are capable of a direct and general solution in the special case in which the Laurent series contains only a finite number of terms involving negative powers of $x - a$. In that case the differential equation (27) may be written in the form

$$(33) \quad \frac{d^n y}{dx^n} + \frac{P_1(x)}{x-a} \frac{d^{n-1} y}{dx^{n-1}} + \frac{P_2(x)}{(x-a)^2} \frac{d^{n-2} y}{dx^{n-2}} + \ldots + \frac{P_n(x)}{(x-a)^n} y = 0,$$

where $P_1, P_2, \ldots P_n$ are expressible as power-series proceeding according to *positive*, integral powers of $x - a$. The exponents r_i are then the roots of the *determinating fundamental equation* of the nth degree

$$(34) \quad r(r-1) \ldots (r-n+1) + P_1(a) r(r-1) \ldots (r-n+2) + \ldots + P_n(a) = 0.$$

After r_i has been obtained from this equation, the method of indeterminate coefficients enables one to find the coefficients of the power-series. In the case of equal roots some of the solutions may contain such terms as $\log (x-a)$, $\{\log (x-a)\}^2$, etc.; the general discussion of the various cases which may arise is rather complicated.

The case in which the equation may be written in the form (33) is usually described as that in which the solutions are *regular* about $x = a$. If they are regular in the vicinity of each singular point, including $x = \infty$, the equation is said to be of the *Fuchsian type*, and may be written as follows:

$$(35) \quad y^{(n)} + \frac{G_{\rho-1}}{\psi} y^{(n-1)} + \frac{G_{2(\rho-1)}}{\psi^2} y^{(n-2)} + \ldots + \frac{G_{n(\rho-1)}}{\psi^m} y = 0,$$

where y', y'', etc., denote the derivatives of y of the first, second order, etc., where

$$(35a) \quad \psi = (x - a_1)(x - a_2) \ldots (x - a_m),$$

$a_1, \ldots a_m$ and ∞ being the singular points, and where G_λ denotes a polynomial in x of degree no higher than λ. The most important special case of such an equation is that of the hypergeometric series, the so-called Gauss equation, which is of the second order and has three singular points, 0, 1, and ∞. Historically, the theory of the Gauss equation, as treated by Riemann, was the origin of the general theory of linear differential equations. A large number of the most important conceptions of the theory of functions are closely connected with this equation. The question of finding the cases in which the general solution is algebraic led Schwarz, Fuchs, and Klein to the remarkable algebraic functions which are connected with the five regular solids. This equation also leads to the general theory of automorphic functions, of which the elliptic functions are a special case.

If, in the vicinity of a singular point, the solutions are regular, they may be developed in series whose coefficients may be determined in the manner indicated. The problem of finding the developments of the solutions in the vicinity of a point where they are not regular is far more difficult and still awaits a satisfactory general solution. A solution, not regular at $x = a$, may have the special form

$$e^{\Omega} (x-a)^{\rho} \psi(x),$$

where ρ is a constant, where $\phi(x)$ is an ordinary power-series in $x-a$, and where

$$\Omega=\frac{a_1}{(x-a)^s}+\frac{a_2}{(x-a)^{s-1}}+\ldots+\frac{a_s}{x-a},$$

so that it differs from a regular integral only by the presence of the factor e^{Ω}. Such an integral, if it exists, is called a *normal integral*. There may also be integrals of a similar form in which, however, $(x-a)^{1/k}$ appears in place of $x-a$, where k is a positive integer. They are called *subnormal*. The conditions for the existence of normal and subnormal integrals have been investigated, but none of these investigations is as yet in a final form. Moreover these normal and subnormal integrals are clearly nothing but very special examples of non-regular integrals. A general theory on such a basis requires a systematic and complete theory of essential singular points of uniform functions of a complex variable. Such a theory, however, does not exist.

It becomes necessary, therefore, to change the method of attack. The general theory shows that, in the vicinity of the singular point $x=a$, a solution exists of the form $(x-a)^{\rho}\phi(x)$, where $\phi(x)$ is, in general, a Laurent series. The question is this: how to determine the exponent ρ and the coefficients of $\phi(x)$. In the regular case, when $\phi(x)$ is an ordinary power-series, substitution of this expression into the differential equation, and comparison of powers of $x-a$, solves the problem. One may do the same thing in general. But then one finds it necessary to solve a system of linear equations infinite in number and with an infinity of unknown quantities. This leads to the notion of *infinite determinants*, due primarily to G. W. Hill. Hill applied infinite determinants just as though they were finite, paying no attention to convergence or rigorous definitions. This deficiency was made up and the whole theory placed upon a solid basis by Poincaré and Koch.

The theory of linear differential equations has served as a basis for practically all that is known about non-linear equations. There are two fundamental properties of the linear equations which render them peculiarly accessible. In the first place it is known, *a priori*, how the arbitrary constants enter into the expression of its general integral; in the second place the singular points of its solutions are *fixed*, *i.e.*, independent of the constants of integration. Other classes of differential equations may be defined which have one or both of these properties. The first-mentioned point of view leads to the differential equations with fundamental solutions. These may be defined in various ways, and have been investigated by Guldberg, Vessiot, Lie, and Wilczynski. The idea of investigating the differential equations with fixed branch-points is due to Fuchs. For equations of the first order he succeeded in formulating the conditions in a very simple theorem. Poincaré then showed that all such equations can be transformed into a Riccati equation, *i.e.*, an equation of the form

$$(36)\qquad \frac{dy}{dx}=a_0+a_1y+a_2y^2,$$

where a_0, a_1, a_2 are functions of x, or else are integrable by quadratures or algebraic functions. Differential equations of the first order with fixed branch-points do not, therefore, as was at first expected, lead to new transcendental functions. For, the Riccati equation may, by the transformation $y=-\frac{1}{a_2z}\frac{dz}{dx}$, be converted into a linear differential equation of the second order. It may be noted, incidentally, that this remark enables us to prove, in a simple manner, the theorem that the anharmonic ratio of any four solutions of a Riccati equation is constant. This is important in geometric applications.

The most important recent investigations in the theory of differential equations, from the standpoint of the theory of functions of a complex variable, are due to Painlevé. A brief account of some of them will indicate their fundamental nature. Let

$$(37)\qquad \frac{dy}{dx}=f(x,y)$$

be an algebraic differential equation of the first order. The general integral will be a function of x and u, u being the constant of integration. We may, instead, consider u as a function of x and y defined by the partial differential equation

$$(38)\qquad \frac{\partial u}{\partial x}+\frac{\partial u}{\partial y}f(x,y)=0.$$

The general integral of (37) is said to be *reducible* if other equations, algebraic in x, y, u, $\frac{\partial u}{\partial x}$, $\frac{\partial u}{\partial y}$, $\frac{\partial^2 u}{\partial x^2}$, etc., may be adjoined to (38) compatible with it without being deducible therefrom. All of the equations of the first order which have been studied are reducible in this sense; for instance, the Riccati equation, the linear equation, etc. In the case of a linear equation the condition $\frac{\partial^2 u}{\partial y^2}=0$ may be thus adjoined; if the equation admits an algebraic integrating factor λ, we may adjoin the condition $\frac{\partial u}{\partial y}=\lambda$; etc. This definition of reducibility may be extended to equations, or systems of equations, of any order.

Applied to equations of the first order, the following theorem results. If an equation of the first order is reducible, only four cases are possible: 1st, the equation is algebraically integrable; 2d, it has an algebraic integrating factor; 3d, the logarithm of the integrating factor has algebraic first derivatives; 4th, a first integral is given by a system of differential equations whose general solution is of the form $u=\frac{au_1+b}{cu_1+d}$, (a, b, c, d being arbitrary constants,) and which may be reduced to a Riccati equation.

Irreducible equations of the first order lead to known results, if we confine ourselves to the case that y shall be a uniform function of x. This is not the case, however, for equations of higher order. Among the equations of the second order, the simplest case is that of the equation

$$(39)\qquad y''=6y^2+x.$$

Its general integral is a uniform function of x, which may be represented as a quotient of two integral transcendental functions in the form $y=\frac{d^2\log u}{dx^2}$, where u is an integral transcendental function which satisfies the equation

(40) $$\tfrac{1}{2}(z'')^2+2(z')^3+xz'-z=0,$$

where $z=\frac{u'}{u}$, and which may, therefore, be represented by an ordinary power-series convergent for all values of x.

Although great progress has been made in this direction, and although greater progress is to be expected as the efforts of mathematicians are being gradually rewarded, the results are meager from the point of view of the mathematical physicist, who would like to refer to the mathematician the questions connected with the integration of a differential equation which may have appeared in some of his investigations. For, very rarely will it happen that such an equation belongs to one of the classes with which the mathematician is prepared to deal. It remains necessary to study such equations directly by methods of successive approximation especially adapted to them, usually upon the assumption that all of the variables that enter be confined to real values. The restriction to real variables in such cases, the systematic and rigorous application of the method of successive approximations, has been productive of many valuable results in recent years, especially in the hands of Picard and Hilbert. The theory of partial differential equations, primarily, has made rapid progress through their efforts, and many mathematicians are following their example. It may, however, be predicted that, even in the theory of partial differential equations, the restriction to real variables will gradually pass away. For, in the case of analytic functions, and these after all are the most important, the characteristic properties are veiled by such a restriction. But a necessary prerequisite for a theory of partial differential equations with complex variables is the theory of functions of several complex arguments; this theory, however, is still in its infancy.

Bibliography.—A. R. Forsyth, ‘A Treatise on Differential Equations’ (3d edition, London, 1903). This contains an account of the more elementary parts of the theory. A. R. Forsyth, ‘Theory of Differential Equations’ (4 volumes published; Cambridge, 1890). In this work the main stress is laid upon the functiontheoretic point of view. E. Picard, ‘Traité d'analyse’ (vols. 2 and 3; Paris, 1893–95). Important principally for the modern theory of partial differential equations. P. Painlevé, ‘Leçons sur la théorie analytique des équations différentielles, professées à Stockholm,’ Sept., Oct., Nov., 1895. Lithographed at Paris, 1897. An account of the most advanced points of view. L. Schlesinger, ‘Handbuch der Theorie der linearen Differentialgleichungen’ (Leipzig, 1895–98). S. Lie, ‘Vorlesungen über Differentialgleichungen mit bekannten infinitesimalen Transformationen,’ bearbeitet und herausgegeben von G. Scheffers (Leipzig, 1891). For further bibliographical indications and for a brief account of the whole subject from the point of view of the expert mathematician, see the various articles on differential equations in ‘Encyclopädie der mathematischen Wissenschaften mit Einschluss ihrer Anwendungen,’ which is now being published in Leipzig. A French edition of this monumental work is also being published.

Ernest J. Wilczynski,
Assistant Professor of Mathematics, University of California.

Equations, Galois' Theory of.—In the 16th century the Italian mathematicians succeeded in solving the cubic and biquadratic equations. Their brilliant achievements must have made it seem probable that the solution of the equations of fifth and higher degrees would soon be found. Such, however, was not to be the case. For two centuries the first mathematicians of the day essayed in vain to solve the quintic. Tschirnhaus, Euler, Vandermonde, Malfatti, and Lagrange have embodied their researches in valuable memoirs, but at the close of the 18th century the solution of the equation of fifth degree seem farther away than ever.

In their apparent defeat, however, lay the germs of ultimate victory. As a result of all these investigations it became manifest that the solution of algebraic equations and certain groups of substitutions of their roots were intimately related. In the case of the general equations of degrees three and four this relation was very clear indeed; it was less clear in regard to the general equation of degree n, and still more hazy in regard to the special equations which had been considered up to that time. It was reserved to Evareste Galois to put these loose ends together and to develop a theory of the solution of algebraic equations at once simple and far-reaching. Indeed, the ideas of Galois are not only fundamental in most algebraic investigations, but they have also been ex ended by Lie and others with great effect to the theory of differential equations. But even here they do not stop. It is in Galois' theory that the notion of a group first came prominently before the mathematical public; a notion which to-day pervades a good part of the whole domain of mathematics.

Galois died at the age of twenty-two (1832). Twice he presented memoirs to the Paris Academy, containing an account of his theory. The first was lost, the second was returned to its youthful author by Poisson as unintelligible. Galois' theory was first made public to the mathematical world in 1846 when Liouville published this latter memoir without comments. In 1858 Betti published an exposition of Galois' theory with complete proofs and some valuable extensions.

Lagrange in his great memoir of 1770–71 developed what he styled a *calcul des combinaisons* and which is in fact the origin of Galois' Theory of Equations. This new *calcul* was further developed in a number of papers by Ruffini, beginning 1799, who tried to demonstrate the impossibility of the algebraic solution of the general equation of degree greater than four by this means; by Gauss (1801) and Lagrange (1808) in the solution of the equations on which the roots of unity depend; and finally by Abel, who, besides being the first to rigorously demonstrate the insolvability of the quintic by radicals (1826), discovered a new class of algebraic solvable equations which occur in the division of the elliptic functions (1829).

The first work on Algebra to contain an account of Galois' theory was the second edition of Serret's ‘Algèbre’ (1866). Since then Galois' theory has been improved and greatly extended by many writers. In particular we mention Jordan, ‘Math. Annalen’ (vol. 1, 1869); ‘Traité des Substitutions’ (1870); Hölder, ‘Math. Annalen’ (vol. 34); Hilbert, Crelle's Journal (vol. 110); Kronecker, 'Festschrift' (1881; reprinted in Crelle, vol. 92). The best exposition of the theory to-day is to be found in H. Weber, 'Algebra' (2 vols., 2d edition, 1898–99). In English there is the translation of Netto's 'Substitutionentheorie' by F. N. Cole and Cajori, 'Theory of Equations' (1904). Brief accounts of the theory are Bolza, 'Theory of Substitution-Groups and its Application to Algebra,' Am. Jour. Math., vol. 13; Pierpont, 'Galois' Theory of Algebraic Equations,' Annals of Math. (1899–1900, vols. 1, 2).

Basal Notions.

Domain of Rationality.—One of the most fundamental notions in Galois' theory is that of a domain of rationality which was first clearly formulated by Abel. When an equation

$$f(x) = a_0x^n + a_1x^{n-1} + \ldots + a_{n-1}x + a_n = 0 \quad (1)$$

offers itself for solution, its coefficients are supposed known. It often happens that other quantics are known, or are assumed as known. Suppose $\lambda, \mu, \ldots \omega$ are such quantics, finite in number. The totality of rational functions of these letters with rational numbers as coefficients constitutes a domain of rationality which we denote by

$$R(\lambda, \mu, \ldots \omega).$$

Thus any element of this domain may be obtained by a finite number of additions, subtractions, multiplications, and divisions performed on the letters $\lambda, \mu, \ldots \omega$. The domain of rationality which we lay at the base of a given algebraic investigation is to some degree a matter of choice. In any case, however, the coefficients of the equations we start with should lie in it.

Every domain must contain the domain $R(1)$, called the absolute domain, and which is simply the totality of rational numbers. For the domain $R(\lambda, \ldots \omega)$ must contain the element $\lambda/\lambda = 1$. It is often desirable to add certain elements $\eta, \zeta, \ldots$ to a domain $R(\lambda, \mu, \ldots)$, forming the new domain $R'(\lambda, \mu, \ldots \eta, \zeta, \ldots)$. The elements $\eta, \zeta, \ldots$ are said to be *adjoined* to R.

Rational Functions in R.—In elementary algebra and in the function theory a rational function of $x, y, z, \ldots$ is an expression of the form

$$\frac{Ax^{m_1}y^{m_2}z^{m_3}\ldots + \ldots}{Bx^{n_1}y^{n_2}z^{n_3}\ldots + \ldots}, \quad (2)$$

where the exponents m, n are non-negative integers and the coefficients are merely independent of the variables $x, y, z, \ldots$ In Galois' theory the term rational function is a much narrower one. In fact the term rational has no meaning unless in connection with a specific domain of rationality. Thus the expression (2) is a rational function of $x, y, \ldots$ in Galois' theory with respect to the domain R, when and only when the coefficients $A, B, \ldots$ lie in R. Thus such a function as (2) may be rational with respect to one domain and not with respect to another. For example,

$$x + \sqrt{-3}y$$

is a rational function of x, y with respect to the domain $R(\rho)$, $\rho = e^{\frac{2\pi i}{3}}$; but it is not rational with respect to $R(1)$ or $R(\sqrt{-5})$. When the denominator in (2) reduces to a constant, it becomes a rational *integral* function.

An equation as (1) is *rational* with respect to R when its coefficients $a_0, a_1, \ldots a_n$ lie in R.

Reducibility and Irreducibility is another basal notion of Galois' theory. The rational integral function of $x, y, z \ldots$,

$$F(x, y, z, \ldots) = Ax^{m_1}y^{m_2}z^{m_3}\ldots + \ldots + Lx^{r_1}y^{r_2}z^{r_3}\ldots, \quad (3)$$

with respect to the domain R is *reducible* in R when it is the product of two or more rational integral functions of $x, y \ldots$ with coefficients in R, viz., $F = G \cdot H \cdot I \ldots$ In this case we say F is divisible by $G, H, \ldots$, which are factors or divisors of F in the domain R. If the expression (3) cannot be split up into two such factors, it is *irreducible* with respect to R. An equation as (1) is reducible or irreducible in R according as its left side is reducible or irreducible in R.

An equation as (1) may be irreducible in one domain and reducible in another. Thus

$$x^2 + x + 1 = 0$$

is irreducible in $R(1)$, but is reducible in $R(\sqrt{-3})$. In fact,

$$x^2 + x + 1 = (x - \rho)(x - \rho^2), \quad \rho = e^{\frac{2\pi i}{3}}.$$

If $\xi_1, \ldots \xi_n$ are the roots of (1), it is obviously reducible in $R(\xi_1, \ldots \xi_n)$. In fact its left side splits up into rational linear factors,

$$f(x) = a_0(x - \xi_1) \ldots (x - \xi_n).$$

A theorem of utmost importance in Galois' theory is the following:

Let $f(x) = 0$, $g(x) = 0$ be rational equations for the domain R, and let $f(x) = 0$ be irreducible in R. If $g(x) = 0$ admits a root of $f(x) = 0$, it admits all the roots of $f(x) = 0$, and $g(x)$ is divisible by $f(x)$.

Equality.—As a third pillar on which Galois' theory rests is the distinction between *formal* and *numerical* equality, as we may designate it for lack of better terms. It is only by such a distinction that Galois was able to extend Lagrange's methods so as to apply to any type of algebraic equation. As long as we are dealing with constants, equality and inequality are of course the same as in arithmetic—they are numerical. What do we mean, however, by the equation

$$\phi(p, q, \ldots) = \psi(p, q, \ldots),$$

ϕ, ψ being rational functions of the variables $p, q, \ldots$ for a domain R? In general R will contain variable elements which then may enter the coefficients of ϕ, ψ. Let us write the above equation

$$\phi(v_1, v_2, \ldots c_1, c_2, \ldots) = \psi(v_1, v_2, \ldots c_1, c_2, \ldots),$$

where v_1, v_2 represent now all the variable elements in ϕ, ψ, among which will be $p, q, \ldots$, while $c_1, c_2, \ldots$ represent constants. By an equation of the above type we mean: *that for each and every set of numerical values $v_1, v_2, \ldots$ can take on consistent with their definition, the resulting numerical value of ϕ is identical with that of ψ.*

When no two of the quantities $\phi, \psi, \chi, \ldots$ are equal we shall call them *distinct* or *unequal.*

The Galoisian Resolvent and Group.

Construction of n!-valued Functions; Indeterminants.—Let

$$f(x) = a_0x^n + a_1x^{n-1} + \ldots + a_n = 0 \quad (1)$$

be an equation whose solution is to be effected. The first thing to do is to choose a domain of rationality R. As already remarked, the nature of R depends partly upon (1) and partly upon our own pleasure. In any case it must contain the coefficients.

Without loss of generality we may suppose its roots unequal. For by means of the greatest common divisor of $f(x)$ and $f'(x)$ we may obtain by rational operations an equation whose roots are the distinct roots of (1).

Let us now adjoin n new variables $u_1, \ldots u_n$ to R, forming a domain R', and introduce the rational function

$$V_1 = u_1x_1 + u_2x_2 + \ldots + u_nx_n. \qquad (4)$$

If we permute the $x_1, x_2, \ldots x_n$ in all possible ways, or, as we say, apply the $n!$ substitution

$$\begin{pmatrix} x_1 & x_2 & \ldots & x_n \\ x_{\iota_1} & x_{\iota_2} & \ldots & x_{\iota_n} \end{pmatrix}$$

of the symmetric group, we get the $n!$ functions

$$V_1, V_2, \ldots V_{n!}. \qquad (5)$$

With these we form the equation

$$F(t; u_1, \ldots u_n) = (t - V_1)(t - V_2) \ldots (t - V_{n!}) = 0, \quad (6)$$

whose coefficients lie in R'. In the discriminant of (6), $D(u_1, \ldots u_n)$, we may give to $u_1, \ldots u_n$ values, $\alpha_1, \ldots \alpha_n$, in R, integral values, even, if we choose, in an infinity of ways so that $D \neq 0$. In that case the quantics (5) are distinct and the roots of (6) thus unequal. The function (4) has thus $n!$ values under the symmetric group. A special case of this function (4) was used by Lagrange; in its general form it was first employed by Abel. Its fundamental importance in the solution of algebraic equations was first brought out by Galois. For this reason the function V in (4) is called the *Galoisian resolvent function*. Besides the function (4) there are obviously an infinity of other $n!$-valued functions. The function (4) is employed on account of its simplicity.

On replacing the u's by the α's these variables disappear. Their introduction was to show the existence of $n!$-valued rational functions of the roots $x_1, \ldots x_n$. Such auxiliary variables which we introduce into our reasoning, and which at any moment can be made to disappear by giving them appropriate special values, are called *indeterminates*. In a primitive way they are used by all mathematicians. Kronecker has shown that they are an implement of immense power in algebraic investigations. Since in the end we can always replace the indeterminates by values lying in our domain, we shall suppose that our domain contains in advance as many of these auxiliary variables as we care to use.

Galoisian Resolvent and Group.—In general the equation (6) is reducible in R, so that

$$F(t) = G(t, u_1, \ldots u_n)G(t, u_1, \ldots u_n) \ldots$$

Let us take now any one of these irreducible factors, say that one which admits V_1 as root, to form the equation

$$G(t, u_1, \ldots u_n) = 0. \qquad (7)$$

This is called the *Galoisian Resolvent of* (1) *for the domain R*. Let its degree in t be m.

Galois showed now that the solutions of (1) and (7) are equivalent problems. In fact every rational function of the roots of (1), and in particular the roots themselves and hence also the roots $V_2, V_3, \ldots V_m$ of (7), are rational functions of V_1. We have therefore for any rational function of the x's

$$\phi(x_1, \ldots x_n) = r_0 + r_1V_1 + r_2V_1^2 + \ldots + r_{m-1}V_1^{m-1}.$$

The advance that is made by considering the equation (7) instead of the original equation (1) lies in the fact that the roots of (7) are rational in any one of them. Let the roots of (7) be

$$V_1, V_2, \ldots V_m.$$

These are obtained from the expression (4) by effecting certain substitutions,

$$s_1 = 1, s_2, \ldots s_m, \qquad (G)$$

on the roots $x_1, \ldots x_m$. These m substitutions G enjoy now three remarkable properties:

1° *Every rational function $\phi(x_1, \ldots x_m)$ of the roots of* (1) *which remains unaltered by G lies in R, or, as we say, is rationally known.*

2°. *If the rational function of the roots $\phi(x_1, \ldots x_m)$ is rationally known, it remains unaltered for the substitutions G.*

3°. *The substitutions G form a group, and there is no other group of substitutions having the properties* 1°, 2°.

This group is called *the Galoisian group of the equation* (1) *for the domain R*. We say for the domain R, because by changing R the irreducible factors of (6) will in general change, and therefore the substitutions G will in general change. The importance of the Galoisian group, or, as we shall say more shortly, *the* Group, of an equation $f(x) = 0$ lies in the fact that an investigation of its structure reveals many of the most important properties the algebraic irrationalities defined by this equation. In particular it affords a rational and uniform scheme for effecting the solution of any algebraic equation. Before entering on this topic let us consider

Some Properties of the Galoisian Group G.

Since the group G of an equation

$$a_0x^n + a_1x^{n-1} + \ldots + a_n = 0 \qquad (1)$$

is unique for a given domain of rationality R, it follows: 1° that the group is independent of the particular $n!$-valued function we take; 2° that we get the same group whichever of the irreducible factors $G(t)$, $G_1(t)$, ... of (6) we may choose; and 3° that these functions G, G_1, ... are all of the same degree.

4°. *In any rational equation*

$$\phi(x_1, \ldots x_n) = \psi(x_1, \ldots x_n)$$

between the roots of (1) *the substitutions of G may be applied, and the result is a true equation.*

This is not true for all substitutions. For example, let

$$f(x) = x^3 - 1 = 0,$$

whose roots are

$$x_m = e^{\frac{2\pi i m}{3}}. \qquad m = 0, 1, 2.$$

Take as domain $R(1)$, and as rational relation

$$x_1x_2 = 1.$$

On applying the substitution

$$\begin{pmatrix} x_0 & x_1 & x_2 \\ x_1 & x_2 & x_0 \end{pmatrix} = (0, 1, 2)$$

this relation becomes,

$$x_0x_2 = 1,$$

which is false.

Group belonging to a Rational Function of the Roots and Rational Functions belonging to a Group.—Let

$$\phi(x_1, \ldots x_n)$$

be a rational function of the roots of (1). Since the group G of (1) contains the identical substitution, ϕ remains unaltered by at least one substitution of G and may remain unaltered by others. *These substitutions form a subgroup of* G called the group belonging to ϕ. On the other hand, let H be a subgroup of G. Any rational function $\phi(x_1, \ldots x_n)$ which remains unaltered by the substitutions of H but is changed by all other substitutions of G is said to belong to H. It is important to note that while the substitutions of the Galoisian group which leave a rational function $\phi(x_1, \ldots x_n)$ unaltered from a group, this property does not hold for substitutions which lie outside G. For example, the sub titutions of the symmetric group S_6 which leave

$$\phi = x_1x_5, \quad x_m = e^{\frac{2\pi i m}{6}}, \quad m = 0, 1, 2, 3, 4, 5,$$

do not form a group. This is due to the fact that the group of the equation

$$x^6 - 1 = 0,$$

the domain being $R(1)$, is not S_6 but a smaller group.

If $\phi(x_1, \ldots x_n)$, $\psi(x_1, \ldots x_n)$ belong to the same subgroup H of the Galoisian group, each can be expressed rationally in terms of the other.

Rational Resolvents.

Let $\phi(x_1, \ldots x_n)$ be a rational function of the roots of

$$a_0x^n + a_1x^{n-1} + \ldots + a_n = 0, \qquad (1)$$

whose group for the domain R is G. Let ϕ belong to a subgroup H of G of index r. Then on applying the substitutions of G to ϕ it will take on r distinct values,

$$\phi, \phi_1, \ldots \phi_{r-1}, \qquad (8)$$

which are called *conjugate functions*. They are in fact roots of an irreducible equation

$$\Phi(y) = (y-\phi)(y-\phi_1) \ldots (y-\phi_{r-1}), \qquad (9)$$

whose coefficients lie in R. It is thus a rational equation. Suppose one of its roots, say ϕ, can be found. If we adjoin it to R, forming a domain R', the group of (1) is no longer G, but H.

Suppose not only ϕ but all the roots of (9) can be found. Their adjunction to R forms a domain R'' for which the group of (1) is the greatest invariant subgroup of G contained in H. In any case the adjunction of one or more roots of (9) produces a reduction of the group of the given equation (1). But in reducing the group of this equation we have made a step in its solution. For when the domain of rationality has been enlarged to such an extent that the group of the equation (1) embraces only the identical substitution, the roots of (1) are rationally known, that is, can be expressed rationally in terms of quantities lying in that domain of rationality. The equation (9) is called a resolvent equation, or more specifically a *rational resolvent*, since its roots $\phi, \phi_1, \ldots$ are rational functions of the roots of the given equation (1).

The group of the resolvent equation (9) is of importance sometimes. In the functions (8) considered as functions of the x's, let us effect the substitutions of the group G. This gives rise to a substitution group Γ in the ϕ's, and this group is the group of the resolvent equation (9), the domain of rationality being that of G, viz., R. The groups G and Γ are isomorphic. To the identical substitution of Γ corresponds the group I above mentioned, viz., the subgroup of G, which leaves all the roots (8) unaltered. To any subgroup Γ_1 of Γ will correspond a subgroup G_1 of G, and conversely. In particular if Γ_1 is an invariant subgroup, G_1 is also invariant.

Galois' Solution of an Equation.

Let G be the group of the equation

$$a_0x^n + a_1x^{n-1} + \ldots + a_n = 0 \qquad (1)$$

for the domain R. Let H_1 be a subgroup of G of index r_1. Let $\phi_1(x_1, \ldots x_n)$ be any one of the infinity of rational functions belonging to H_1. Then ϕ_1 is root of a rational resolvent $\Phi_1(y) = 0$ of degree r_1. On solving $\Phi_1 = 0$ and adjoining one or more of its roots to form a new domain R_1, the group of (1) is now a subgroup of G_1 of G. Let H_2 be a subgroup of G_1 of index r_2, to which belongs the rational function $\phi_2(x_1, \ldots x_n)$. This is the root of a resolvent $\Phi_2(y) = 0$ of degree r_2. On solving $\Phi_2 = 0$ and adjoining one or more of its roots to form a new domain R_2, the group of (1) is now a subgroup G_2 of G_1. As the order of the groups $G, G_1, G_2, \ldots$ decreases, we must eventually arrive at the identical group when the roots of (1) are rationally known. Since the group G usually admits quite a variety of subgroups, and since the functions ϕ belonging to a given subgroup are infinite in number, Galois' theory shows that the number of ways for solving a given equation is endless. At the same time it clearly shows that the number of distinct ways is usually quite limited, depending on the subgroups of G.

Among the solutions of the equation (1) which Galois' theory offers, one class is particularly interesting, depending on a

Series of Composition.—This is defined as follows: Let G_1 be an invariant subgroup of G, such that G contains no invariant subgroup containing G_1. It is then a *maximum invariant* subgroup of G. If G has no maximum invariant subgroup besides the identical group, it is *simple*. The series of groups

$$G, G_1, G_2, \ldots G_\lambda = 1, \qquad (10)$$

such that each is a maximum invariant subgroup of the preceding group, is called a *series of composition of* G. If the index of G_m under G_{m-1} is r_m, the numbers $r_1, r_2, \ldots r_\lambda$ are called *the factors of composition*. It may be possible to decompose a group G into a series of composition in more than one way. Thus the cyclic group C_6,

$$1, s, s^2, s^3, s^4, s^5,$$

where $s = \begin{pmatrix} x_1 x_2 x_3 x_4 x_5 x_6 \\ x_2 x_3 x_4 x_5 x_6 x_1 \end{pmatrix} = (1, 2, 3, 4, 5, 6)$ admits the series

$$C_6, A, 1$$

and

$$C_6, B, 1,$$

where

$$A = \{1, s^2, s^4\}, \quad B = \{1, s^3\}.$$

The factors of composition of the first series are 2, 3, while those of the second series are 3, 2. They are thus the same aside from their order. A theorem of *Jordan* states that *however a group be decomposed in a series of composition, the factors of composition are the same aside from their order.*

What makes the solution of an equation by means of a series of composition so remarkable is the fact that the resolvents $\Phi_1 = 0$, $\Phi_2 = 0, \ldots$, $\Phi_\lambda = 0$ corresponding to the subgroups G_1, $G_2 \ldots G_{\lambda-1}$ of (10) have groups $\Gamma_1, \Gamma_2, \ldots \Gamma_\lambda$ for their respective domains which are simple. Their orders are the factors of composition. Moreover, any root of one of these equations is a rational function of any root of that equation. Thus on adjoining one of its roots the same effect is produced as adjoining all. Finally, the resolvent equations $\Phi = 0$ are the simplest possible.

Cyclic Equation of Prime Degree.—When the group G of an equation $F(x) = 0$ is a cyclic group of prime order p its solution is readily effected, as Abel showed. Let the roots of $F = 0$ be $x_0, x_1, \ldots x_{p-1}$, and let $\gamma = (0, 1, \ldots p-1)$. Then

$$G = \{1, \gamma, \gamma^2, \ldots \gamma^{p-1}\}.$$

For the case in hand we may suppose the pth roots of unity $\rho, \rho^2, \ldots$ lie in the original domain of rationality. Consider the rational functions

$$\theta_h = x_0 + \rho^h x_1 + \ldots + \rho^{h(p-1)} x_{p-1}; \quad h = 1, 2, \ldots p-1.$$

On applying γ they go over into $\rho^{-h}\theta$. Hence $\theta_h^p = \theta_h$ are unaltered by γ and hence for G. They are therefore rationally known. On extracting a pth root we get

$$x_0 + \rho^h x_1 + \ldots + \rho^{h(p-1)} x_{p-1} = \sqrt[p]{\theta_h}.$$

This system of $p-1$ equations together with

$$x_0 + x_1 + \ldots + x_{p-1} = \sqrt{\theta_0}$$

gives

$$x_s = \frac{1}{p} \sum_{h=0}^{p-1} \rho^{-hs} \sqrt[p]{\theta_h}, \quad s = 0, 1, \ldots p-1.$$

The pth roots which enter here must be determined uniquely in terms of one of them, say $\sqrt[p]{\theta_1}$. The others are rational in this one, for

$$(x_0 + \rho^h x_1 + \ldots + \rho^{(p-1)h} x_{p-1})$$
$$(x_0 + \rho x_1 + \ldots + p^{p-1} x_{p-1})^{p-h} = A_h$$

remains unchanged for γ and hence for G. Hence these A_h are rationally known. We have now

$$x_s = \frac{1}{p\theta_1} \sum_h \rho^{-hs} \left(\sqrt[p]{\theta_1}\right)^h A_h.$$

This result gives the theorem: *Cyclic equations of prime degree can be solved algebraically*, i.e., *by the extraction of roots from known quantities.*

Algebraic Solution of an Equation.—Let the equation

$$a_0 x^n + a_1 x^{n-1} + \ldots + a_n = 0 \qquad (1)$$

have a group G for a certain domain R, whose factors of composition

$$r_1, r_2, \ldots$$

are all primes. Then (1) can be solved algebraically. For the corresponding chain of resolvents

$$\Phi_1 = 0, \quad \Phi_2 = 0, \ldots$$

have groups of prime orders $r_1, r_2, \ldots$; they are therefore cyclic equations, whose solution has just been effected. Since, as will be set forth later at more length, it is never necessary to employ other than rational resolvents, the above result leads to Galois' Criterion for the Solution of an Equation by Radicals. *In order that* (1) *admit an algebraic solution it is necessary and sufficient that the factors of composition of its Galoisian group consist of primes only.*

Application to the Solution of the Biquadratic

$$x^4 + a_1 x^3 + a_2 x^2 + a_3 x + a_4 = 0. \qquad (11)$$

For simplicity let us suppose its coefficients are independent variables. Let the original domain of rationality R embrace besides the coefficients a cube root of unity ρ. Then the group of (11) is the symmetric group S_4. As subgroups of S_4 we note the alternate group A_4, the axial group $G_4 = \{1, (12)(34), (13)(24), (14)(23)\}$, and the semiaxial group $G_2 = \{1, (12)(34)\}$. The groups S_4, A_4, G_4, G_2, 1 form a series of composition whose factors are obviously

$$2, 3, 2, 2.$$

As they are primes, the equation (11) admits an algebraic solution. To solve (11) let us proceed with Starkweather as follows: To form our first resolvent, let us use the subgroup A_4, and take as function belonging to this group

$$\phi = (x_1 - x_2)(x_1 - x_3)(x_1 - x_4)$$
$$(x_2 - x_3)(x_2 - x_4)(x_3 - x_4) \qquad (12)$$

The corresponding resolvent is

$$\Phi = \phi^2 - \Delta = 0, \qquad (13)$$

where Δ is the discriminant of (11).

On adjoining $\phi = \sqrt{\Delta}$ our domain is $R_1(R, \sqrt{\Delta})$, for which the group of (11) is A_4.

A subgroup of A_4 is G_4. A rational function belonging to this is

$$\psi = x_1 x_2 + x_3 x_4.$$

This gives the resolvent

$$\Psi = \psi^3 - a_2 \psi^2 + (a_1 a_3 - 4a_4)\psi$$
$$- \{a_4(a_1^2 - 4a_2) + a_3^2\} = 0. \qquad (14)$$

The solution of this cubic, which is a cyclic equation, gives ψ as a known explicit function of quantics in R_1. On adjoining ψ we get the domain $R_2(R, \sqrt{\Delta}, \psi)$, for which the group of (11) is G_4. The next subgroup we take is G_2 to which belongs

$$\chi = x_1 + x_2 - (x_3 + x_4).$$

This gives the resolvent

$$X = \chi^2 - (4\psi + a_1^2 - 4a_2) = 0.$$

The extraction of a square root gives χ, whose adjunction produces the domain $R_3(R, \sqrt{\Delta}, \psi, \chi)$, for which the corresponding group of (11) is G_2. The last group we take is the identical group, to which belongs x_1. The corresponding resolvent is

$$x^2+\tfrac{1}{2}(a_1-\chi)x+\tfrac{1}{2}\left(\psi+\frac{2a_3-a_1\psi}{\chi}\right)=0.$$

The solution of this quadratic gives x_1. Its adjunction gives the domain $R_4(R, \sqrt{\Delta}, \psi, \chi, x_1)$, for which the group consists only of the identical substitution. Hence all the other roots of (11), viz., x_2, x_3, x_4, must lie in R_4. This is indeed so, for

$$x_2=x_1-\tfrac{1}{2}a_1+\tfrac{1}{2}\chi.$$

To get x_3, x_4, we note that if ψ', ψ'' denote the two other roots of (14),

$$\alpha=\psi'-\psi''=\frac{(\psi-\psi')(\psi-\psi'')(\psi'-\psi'')}{(\psi-\psi')(\psi-\psi'')}.$$

Here the numerator is the square root of the discriminant of (14), which, as is well known, is the same as the discriminant Δ of (11). The denominator is obviously $\dfrac{d\Psi}{d\psi}$. Thus

$$\alpha=\frac{\sqrt{\Delta}}{\Psi'}=(x_1-x_2)(x_3-x_4),$$

a quantity lying in R_4.

Moreover, x_1, x_2 being already found, $x_1-x_2=\beta$ and $x_1+x_2=\gamma$ are known; also $x_1+x_2+x_3+x_4=\gamma+x_3+x_4=-a_1$ is known. This last with $\beta(x_3-x_4)=\alpha$ gives x_3 and x_4.

Lagrange's Solution instead of employing a series of composition uses the following subgroups, A_4, O, G_2, 1, where

$$O=\{1, (1324), (13)(24), (1423), (12), (34), (12)(34), (14)(23)\}.$$

As rational function belonging to A_4 Lagrange uses the function (12), which gives rise to the resolvent (13). As rational function belonging to O, Lagrange takes

$$\theta=\{x_1+x_2-(x_3+x_4)\}^2,$$

whose conjugate values are

$$\theta_1=\{x_1+x_3-(x_2+x_4)\}^2,\quad \theta_2=\{x_1+x_4-(x_3+x_2)\}^2.$$

The corresponding resolvent is

$$\Theta=\theta^3-(3a_1^2-8a_2)\theta^2+(3a_1^4-16a_1^2a_2+16a_2^2+16a_1a_3-64a_4)\theta-(a_1^3-4a_1a_2+8a_3)^2=0.$$

For the subgroup G_2 he takes

$$\eta=x_1+x_2-(x_3+x_4),$$

which gives the resolvent

$$H=\eta^2-\theta=0.$$

For the identical group 1, Lagrange uses

$$\omega=x_1+x_3-(x_2+x_4),$$

which gives the resolvent

$$\Omega=\omega^2-\theta_1=0.$$

For the domain $R'(R, \sqrt{\Delta}, \theta_1, \theta_2, \theta_3, \eta, \omega)$, the group of the biquadratic is (1), and its roots therefore lie in R'. In fact we have

$$x_1+x_2-x_3-x_4=\sqrt{\theta},$$
$$x_1+x_3-x_2-x_4=\sqrt{\theta_1},$$
$$x_1+x_4-x_3-x_2=\sqrt{\theta_2},$$
$$x_1+x_2+x_3+x_4=-a_1.$$

From which we get

$$x_s=\tfrac{1}{4}(-a_1+\sqrt{\theta}+\sqrt{\theta_1}+\sqrt{\theta_2}),\ s=1, 2, 3, 4.$$

Here we choose at will the signs of $\sqrt{\theta}$, $\sqrt{\theta_1}$. The sign of $\sqrt{\theta_2}$ is then determined, for

$$\sqrt{\theta}\sqrt{\theta_1}\sqrt{\theta_2}=4a_1a_2-a_1^3-8a_3.$$

Abelian Equations.—Let G be the group of an equation $f(x)=0$ for a certain domain. If the substitutions of G are commutative, that is, if $s_\iota s_\kappa=s_\kappa s_\iota$ for any two substitutions s_ι, s_κ of G, the equation $f=0$ is called Abelian in honor of Abel, who first studied them. We may show at once that every subgroup of G is invariant and that its factors of composition are all primes. Hence *all Abelian equations can be solved algebraically.* The most important equations of this type are the equations of degree $\phi(n)$ on which the nth roots of unity depend. Here $\phi(n)$, called the *totient of n*, is

$$n\left(1-\frac{1}{p}\right)\left(1-\frac{1}{q}\right)\ldots,$$

where p, q, ... are the different prime factors of n. The domain of rationality is $R(1)$.

Equation of Degree >4.—The group of the equation (1) when no restrictions are placed on the coefficients, *i.e.*, when they are independent variables, and when the domain of rationality contains not only the coefficients but any constants, is the symmetric group. When $n=2$, 3, 4, its factors of composition are primes. Not so when $n>4$. In this case its only invariant subgroup besides the identical group is the alternate group whose order is $\frac{1}{2}n!$. Thus the factors of composition are 2, $\frac{1}{2}n!$. The latter is not a prime. We have thus *Abel's Theorem: Equations of degree >4, whose group is the symmetric group, cannot be solved algebraically; i.e.*, their roots cannot be found by extracting roots from known quantities.

We have just observed that when the coefficients of an equation of degree >4 are independent variables, it cannot be solved algebraically. From that we cannot, however, deny that *every* equation of degree >4 with constant coefficients *may* admit an algebraic solution. This important question was finally settled by Hilbert, who showed that there are an infinity of equations of any degree with rational integral coefficients whose group in $R(1)$ is the symmetric group.

Irrational Resolvents.

Up to the present we have considered the effect on the Galoisian Group of an equation, of adjoining roots of rational resolvents to the current domain of rationality. In many investigations it is important to consider the adjunction of roots of equations which may not be rational functions of the roots of the given equation. Equations whose roots are not rational functions of the roots of the given equation are called *irrational resolvents* when used in the solution of the given equation. A theorem which lies at the foundation of this subject is due to Kronecker. *Let $f(x)=0$, $g(y)=0$ be two rational irreducible equations for the domain R of degrees m, n respectively. If on adjoining a root x_1, of $f=0$, $g(y)$ becomes reducible, the adjunction of a root y_1, of $g=0$, will make $f(x)$ reducible. If $\phi(x)$, $\psi(x)$ of degrees α, β, respectively, be the* *irreducible factors for the new domains that x_1, y_1 satisfy, then*

$$\frac{m}{\alpha}=\frac{n}{\beta}.$$

As an important corollary of Kronecker's theorem we have: Let the adjunction of y_1 reduce the group G of $f(x)=0$ to an invariant subgroup of index i. Then n is a multiple of i and hence never less than i. When $n=i$ (and this is always the case if n is a prime) $g(y)=0$ is a rational resolvent.

Another theorem of great importance in this connection is due to Jordan. *If the adjunction of all the roots of $g(y)=0$ reduces G to a subgroup G_1 of index i, the adjunction of all the roots of $f(x)$ reduces the group H of $g(y)$ to a subgroup H of index k. The two groups G_1, H_1 are invariant and $i=k$. Finally, when H is simple $g(y)=0$ is a rational resolvent.*

Application to Some Celebrated Problems.—The Delian Problem or duplication of the cube requires the solution of

$$x^3-2=0$$

by rule and compass. The construction of the regular polygons by rule and compass is another famous problem of antiquity. Its solution depends upon the irreducible equation of degree $\phi(n)$ already referred to. That the Delian Problem is impossible follows at once from the theorem: *In order that a root, real or imaginary, of an irreducible equation $f(x)=0$ can be constructed geometrically it is necessary that the degree of f be a power of two.* From this theorem we also conclude: *The necessary and sufficient condition that a regular polygon of n sides can be constructed by rule and compass is that the totient of n is a power of two.*

Another famous question is the *Casus Irreducibilis* of cubic equations. The theory of irrational resolvents enables us to prove readily the following general theorem: *An irreducible equation of degree n whose roots are all real can never be solved by real radicals alone if n contains other factors than two.*

That the casus irreducibilis is indeed such follows as corollary of this theorem.

Hölder's Theorem.—One of the most important and fundamental contributions to Galois' theory in recent years is a theorem of Hölder. Speaking roughly, it asserts that however the solution of a given equation $f(x)=0$ be conducted, sometime in the course of the solution certain simple equations whose groups are uniquely determined and known in advance must be employed. When the group of $f(x)=0$ is simple (in which case we say $f(x)$ is simple) it can be solved by no other simple equation $g(y)=0$ essentially different from $f=0$. The solution of any given equation therefore depends upon a chain of simple equations. But of all simple equations belonging to a given group certain ones will enjoy peculiar properties which will recommend their selection as *normal* equations. The reduction of the given equation to these normal equations is a problem by itself.

The Solution of the Quintic.

We have seen that the equation of fifth degree $Q=0$ whose group is the symmetric group cannot be solved by means of radicals, *i.e.*, by resolvents of the type $x^m-a=0$. On adjoining the square root of its discriminant $\sqrt{\Delta}$, the group of $Q=0$ reduces to the alternate group A_5 of 60 substitutions. But A_5 is simple. Thus $Q=0$ is a simple equation for the domain $R(\sqrt{\Delta})$. Other algebraic equations having this group arise in the theory of linear differential equations, and also in the theory of elliptic functions. In fact the hypergeometric function

$$F(\alpha,\beta,\gamma,x)=1+\frac{\alpha\cdot\beta}{1\cdot\gamma}x+\frac{\alpha\cdot\alpha+1\cdot\beta\cdot\beta+1}{1\cdot2\cdot\gamma\cdot\gamma+1}x^2+\ldots$$

is a solution of a very simple differential equation of the second order $G=0$. For variable α, β, γ it represents a new transcendent; but for certain values of these parameters it reduces to the elementary functions; *e.g.*, it may become algebraic. In seeking for these latter cases Schwarz was led to introduce a new variable s, the quotient of two fundamental integrals of $G=0$. This variable for certain values of α, β, γ satisfies the equation

$$J(s)=1728x\,f^5(s)+H^3(s)=0,$$

where

$$f(s)=s(s^{10}+11s^5-1),$$
$$H(s)=s^{20}-288s^{15}+494s^{10}+288s^5+1.$$

The equation $J=0$ stands in so intimate relation with the icosahedron that it is called the icosahedral equation. Indeed if we project stereographically the icosahedron on the s-plane, the centre being at the origin, the 12 vertices and the middle points of the 20 faces will be precisely the roots of f and H respectively.

From this it is easy to conclude that the group of $J=0$ is formed of the 60 rotations which leave the icosahedron unchanged. Klein has shown that the icosahedral equation whose roots are very simple known functions of $F(\alpha,\beta,\gamma,x)$ can be put in connection with $Q=0$. The equation $J=0$ may thus be considered as a normal resolvent of the quintic.

A normal resolvent which springs from the elliptic functions is the following: In trigonometry one of the problems is to express $\sin\frac{x}{n}$ in terms of $\sin x$, n a prime number. This may be done algebraically, as is readily shown. In the elliptic functions the same problem arises. Here the algebraic relation between $\mathrm{p}\left(\frac{u}{n},\ \omega_1\ \omega_2\right)$ and $\mathrm{p}(u,\ \omega_1\ \omega_2)$ is of degree n^2-1. The solution of this equation depends upon an equation of degree $n+1$ called an equation of transformation. For $n=5$ such an equation is

$$\Delta^2y^6+10\Delta y^3-12g_2y+5=0, \tag{15}$$

whose group is the above A_5 and whose roots are

$$\left(\mathrm{p}\frac{2\omega_1}{5}-\mathrm{p}\frac{4\omega_1}{5}\right)^{-1}$$

and

$$\left(\mathrm{p}\frac{2\omega_2+48r\omega_1}{5}-\mathrm{p}\frac{4\omega_2+96r\omega_1}{5}\right)^{-1},$$
$$r=0,1,2,3,4.$$

Here Δ is the discriminant $g_2{}^3-27g_3{}^2$. How equations of this type could be set in relation with the quintic was first shown by Hermite in 1858. The equation (15) was used by Kiepert. It forms a very convenient normal resolvent of the quintic.

Having found in the elliptic functions convenient normal resolvents for the quintic, we might hope to employ the equations of transformation of higher orders to solve the general equations of higher degrees. The consideration of their groups, however, shows very easily that this is not possible. To find suitable equations we must pass from the elliptic to the hyperelliptic functions. By their aid the general equation of every degree can be solved.

JAMES PIERPONT,
Professor of Mathematics, Yale University.

Equations, General Theory of. The theory of equations finds its origin in efforts to solve the equations which arise in the applications of algebra to problems in pure geometry or in applied mathematics. In the exposition of this theory a rational integral algebraic function of x arises which may be defined as follows:

$$f(x) \equiv a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \ldots + a_{n-1}x + a_n.$$

It is assumed here that the exponent n is a positive integer and that the coefficients a_0, a_1, $a_2, \ldots, a_n$ are algebraic numbers independent of x. If this polynomial is put equal to zero, we have an equation of the nth degree. Any value of the variable x which makes the value of the polynomial zero is said to «satisfy the equation» $f(x)=0$ and is called a «root» of the equation. Thus, -1 is a root of the equation $x^3+x+2=0$, because $(-1)^3+(-1)+2=0$.

Fundamental Theorems about Roots.—That at least one root of the equation $f(x)=0$ always exists is a fundamental theorem which it is somewhat difficult to establish rigorously. The proofs usually given in elementary texts lack rigor. Among the most satisfactory demonstrations are the four given by C. F. Gauss and the one based on the theory of functions, given by A. L. Cauchy. Granted that every equation of the nth degree has at least one root, it is easy to show that it has n roots and no more. An equation of the second dergee (a «quadratic equation») has two roots, one of the third degree (a «cubic equation») has three roots, one of the fourth degree (a «quartic» or «biquadratic equation») has four roots, and so on. The proof of this theorem may be outlined as follows: If r_1 is a root of $f(x)=0$, then $f(x)$ is divisible by $x-r_1$ without a remainder, so that $f(x)=(x-r_1)f_1(x)$, where $f_1(x)$, the quotient, is of the $(n-1)$th degree. If r_2 is a root of $f_1(x)=0$, then in the same way $f_1(x)=(x-r_2)f_{,,}(x)$, and $f(x)=(x-r_1)(x-r_2)f_{,,}(x)$. Proceeding in this manner, the degrees of the successive quotients diminish by unity at every step, until finally a binomial quotient of the first degree of the form $a_0(x-r_n)$ is obtained. We then have $f(x)=a_0(x-r_1)(x-r_2)\ldots(x-r_n)=0$. There are here n binomial factors and no more, each of which, when equated to zero, yields a root. In special cases some of these roots may be equal to each other. Such roots are called «equal» or «multiple» roots.

There are important relations existing between the roots and the coefficients of an equation. From the equalities

$$(x-r_1)(x-r_2)=x^2-(r_1+r_2)x+r_1r_2=0;$$

$$(x-r_1)(x-r_2)(x-r_3)=x^3-(r_1+r_2+r_3)x^2 + (r_1r_2+r_1r_3+r_2r_3)x-r_1r_2r_3=0;$$

$$\cdots\cdots\cdots\cdots$$

$$(x-r_1)(x-r_2)\ldots(x-r_n)=x^n -(r_1+r_2+\ldots+r_n)x^{n-1} +(r_1r_2+r_1r_3+\ldots+r_{n-1}r_n)x^{n-2} -\ldots+(-1)^nr_1r_2\ldots r_n=0$$

we see that in the equation $f(x)=0$, when $a_0=1$, the coefficient a_1 of the second term is equal to minus the sum of the roots; the coefficient a_2 of the third term is equal to the sum of the products of the roots, taken two by two; the coefficient a_3 of the fourth term is equal to minus the sum of the products of the roots, taken three by three; and so on, until finally we arrive at the last coefficient, a_n, which is equal to $(-1)^n$ times the product of all the roots. The coefficients of the equation are said to be *symmetric functions* of the roots, that is, functions in which any two roots may be interchanged without altering the value of the function. As an illustration take $2x^3+4x^2+6x-5=0$. To make $a_0=1$, divide through by 2. Then the sum of the three roots is -2, the sum of their products, taken two by two, is 3, the product of all three roots is $\frac{5}{2}$.

The roots of an equation may be complex (*i.e.*, imaginary) quantities. (See ALGEBRA.) Thus the equation $x^2+x+1=0$ has the two complex roots $\frac{1}{2}(-1+i\sqrt{3})$ and $\frac{1}{2}(-1-i\sqrt{3})$, where $i\equiv\sqrt{-1}$. If the coefficients of the equation $f(x)=0$ are all real, then it can be shown that, if complex roots occur at all, they occur in conjugate pairs; that is, if $a+ib$ is a root, then $a-ib$ is likewise a root. From this it follows at once that no cubic or other equation of odd degree and with real coefficients can have all its roots complex. Considerable information on the character of the roots can usually be secured from «Descartes' Rule of Signs,» which may be stated as follows: *An equation with real coefficients has as many positive roots as it has variations in sign, or fewer by an even number.* A variation is said to exist whenever two successive terms have opposite signs. Thus there are two variations in $+--+$. The theorem may be proved from the consideration that every time that a new positive root is introduced into an equation, by multiplying $f(x)$ by $(x-r)$, the number of variations is increased by an odd number. Applying Descartes' Theorem to the equation $x^6-x^5+x^4+2x^2-5=0$, observe that the sequence of signs is $+-++-$. There are three variations; hence, the equation has either three or one positive root. To apply the theorem to negative roots, we first transform the given equation into a new one whose roots are the same as those of the given equation, excepting in sign. This can be done by writing $-x$ in place of x. The above sextic then becomes $x^6+x^5+x^4+2x^2-5=0$. This transformed equation has one variation; hence, by Descartes' Rule (*q.v.*), it has one positive root, and the given equation has one negative root. As the total number of roots is six and the number of real roots is four or two, it follows that either two or four of the roots are complex. By the same reasoning we can show that $x^5-1=0$ has one positive and four complex roots and that $x^4+x^2+1=0$ has all its roots complex. In some cases, as in $x^4+x^3-x^2+5=0$, Descartes' Rule gives but little information.

Strenuous efforts have been put forth by mathematicians to discover theorems by which the exact number of real and of complex roots of equations with real coefficients can always be determined. The most noted result of these efforts is the theorem of J. C. F. Sturm, discovered in 1829. Sturm's theorem tells the number of complex roots, and the number of real roots within a given interval, with unfailing certainty; but it labors under the disadvantage of being laborious in its application. Hence it is commonly used only when the simpler methods fail to give the wanted information. We state the theorem for the special case when $f(x)=0$ has no equal roots. Let $f'(x)$ be the first derived function of $f(x)$. (See CALCULUS.) Then proceed with the process of finding, by division, the highest common factor of $f(x)$ and $f'(x)$, with this modification, that the sign of each remainder be changed before it is used as a divisor. Continue the process until a remainder is reached which does not contain x, and change the sign of that also. The functions $f(x)$, $f'(x)$, together with the several remainders with their signs changed, viz., $f_2(x)$, $f_3(x)$, . . . , $f_n(x)$, are called «Sturm's functions.» Sturm's theorem is as follows: *If $f(x)=0$ has no equal roots, let any two real quantities a and b be substituted for x in Sturm's functions, then the difference between the number of variations of sign in the series when a is substituted for x and the number when b is substituted for x expresses the number of real roots of $f(x)=0$ between a and b.* To make this clearer, take $f(x)=x^3-x^2-10x+1$, then $f'(x)=3x^2-2x-10$, $f_2(x)=62x+1$, $f_3(x)=38{,}313$. For the indicated values of x the signs of the Sturmian functions are as follows:

x	$f(x)$	$f'(x)$	$f_2(x)$	$f_3(x)$
∞	+	+	+	+
4	+	+	+	+
3	−	+	+	+
1	−	−	+	+
0	+	−	+	+
−2	+	+	−	+
−3	−	+	−	+
$-\infty$	−	+	−	+

Since $x=\infty$ gives no variations and $x=-\infty$ gives three variations, there are three real roots between ∞ and $-\infty$. Hence there are no complex roots. The real roots lie between 3 and 4, 0 and 1, −2, and −3.

Transformations of Equations.—The study of the properties of an equation is frequently facilitated by the transformation of the given equation into a new one whose roots (coefficients) bear a given relation to the roots (coefficients) of the original equation. Thus, in applying Descartes' Rule to negative roots we transformed the equation into another whose roots were numerically the same, but differed in sign. If the roots of the new equation are to be m times those of the one given, we place $y=mx$ and substitute y/m for x. For instance, if the roots of the transformed equation are to be ten times those in

$x^3-x^2-2x+5=0$, we get $\frac{y^3}{1000}-\frac{y^2}{100}-\frac{2y}{10}+5=0$,

or $y^3-10y^2-200y+5000=0$. The result is obtained more easily by the rule: *Multiply the second term by m, the third by m^2, and so on.* If the roots of the new equation are to be the reciprocals of the roots of the old we write $x=\frac{1}{y}$. A more important transformation is the one of diminishing the roots by a given number h. We have here $y=x-h$. Substituting $y+h$ for x in $a_0x^n+a_1x^{n-2}+a_2x^{n-2}+\ldots+a_n=0$, we obtain

$$a_0(y+h)^n+a_1(y+h)^{n-1}+a_2(y+h)^{n-2}+\ldots+a_n=0.$$

Expanding the binomials and collecting like terms, we obtain, let us suppose,

$$A_0y^n+A_1y^{n-1}+A_2y^{n-2}+\ldots+A_n=0.$$

Writing $x-h$ for y we get

$$A_0(x-h)^n+A_1(x-h)^{n-1}+\ldots+A_{n-1}(x-h)+A_n=0,$$

which differs from the original equation merely in form. This new form suggests an easy way for carrying out the actual computation. Dividing the left member by $x-h$, the remainder obtained is seen to be A_n, the absolute term. Dividing the quotient thus obtained by $x-h$, the remainder is A_{n-1}. By repeating this process the remaining coefficients of the required equation are secured. The process, called «synthetic division,» is very convenient in this transformation. Suppose we desire to transform $x^4+8x^3-x+6=0$ into another in which the second term is wanting. The sum of the roots is −8; hence, to cause x^3 to disappear, we must increase each root by 2 (*i.e.*, diminish by −2). Dividing successively by $x+2$ we obtain the coefficients −40, 63, −24, 0, 1, and the required equation is $x^4-24x^2+63x-40=0$.

The transformations thus far considered are all special cases of the so-called *homographic* transformation, in which $y=\frac{ax+b}{cx+d}$, a, b, c, d being constants. Thus, if $a=d=1$ and $c=0$, we have the preceding transformation. The homographic transformation is of interest in geometery, in the study of homographic ranges of points. The most general rational algebraic transformation of the roots of an equation $f(x)=0$ of the nth degree can always be reduced to an integral transformation of a degree not higher than the $(n-1)$th, and can, therefore, be represented by the relation

$$y=d_1+d_2x+d_3x^2+\ldots+d_nx^{n-1}.$$

This last is known as the «Tschirnhausen transformation,» by which Tschirnhausen in 1683 hoped to be able to reduce the general equation of the nth degree to the binomial form $x^n-a=0$, which is always solvable. But this transformation to the binomial form can be effected only for general equations that are lower than the fifth degree.

Solution of Equations.—This subject resolves itself into two quite distinct parts: (1) The solution of numerical equations (*i.e.*, equations whose coefficients are given numbers) by some method of approximation to the exact value of the roots; (2) the solution of equations, whose coefficients are either given numbers or letters, by operations which will give the accurate values of the roots, expressed in terms of the coefficients,—such expressions to involve no other processes than addition, subtraction, multiplication, division, and the extraction of roots. The former is called a solution *by approximation*, the second is called the *algebraic* solution of equations. In the former each root may be found separately, in the latter a general expression is obtained which represents all of the roots indifferently. The former is of importance to the practical computor, the latter is of special interest to the pure mathematician. The solution by approximation can be effected for equations of any degree; the algebraic solution is impossible for general equations of the fifth or of higher degrees. (See EQUATIONS, GALOIS' THEORY OF.)

Algebraic Solution of Equations.—The algebraic solution of the quadratic equation $ax^2+bx+c=0$ is well known. (See ALGEBRA.) The algebraic solution of the cubic, due to Scipio Ferro and Tartaglia, and first published by H. Cardan in 1545, is known as «Cardan's solution.» To effect it, first transform the general cubic equation so that the second term shall be wanting. This done, we have $x^3+ax+b=0$. Putting $x=y+z$ we obtain

$$y^3+3yz(y+z)+z^3+a(y+z)+b=0,$$

or $$y^3+z^3+(3yz+a)(y+z)+b=0.$$

We may subject y and z to any second condition which is not inconsistent with $x=y+z$. It will be convenient to assume $3yz+a=0$. Then $y^3+z^3+b=0$, or, substituting for z its value $-a/3y$, we obtain $y^6+by^3=\frac{a^3}{27}$ and

$$y^3=-\frac{b}{2}\pm\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}.$$

$$z^3=-y^3-b=-\frac{b}{2}\mp\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}.$$

Since $x=y+z$, we have

$$x=\sqrt[3]{-\frac{b}{2}+\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}}+\sqrt[3]{-\frac{b}{2}-\sqrt{\frac{b^2}{4}+\frac{a^3}{27}}}.$$

Since y^3 and z^3 have each three cube roots, it might seem as if $y+z$ or x had altogether nine values. As the cubic has only three roots, this cannot be. Of the nine values, six are excluded by the relation $3yz+a=0$, which y and z must satisfy. Eliminating z between $x=y+z$ and $3yz+a=0$, we get $x=y-\frac{a}{3y}$, where y has the three values obtained from the expression for y^3 given above. This last expression for x does not involve the difficulties of the first expression. If the numerical values of the coefficients a and b are given, the numerical values of the roots may be obtained by substituting the values of a and b in the above expression for x. In any case, this mode of computing x is more laborious than Horner's method of approximation (explained below), but when all three roots of the cubic are real and distinct, an unexpected difficulty is encountered. In this case $\frac{b^2}{4}+\frac{a^3}{27}$ represents a negative number. As the square root of a negative number is a complex (imaginary) number, we are required to find the cube root of a complex number. But there exists no convenient arithmetical process for doing this. Nor is there any way of avoiding the complex radicals and of expressing the values of the real roots by real radicals. This is the famous «irreducible case» in the solution of the cubic. Its interest is purely theoretical. The practical computor experiences no difficulty, for he can always find the values of x by the methods of approximation

Since Cardan's time a great many different algebraic solutions of the cubic and also of the quartic have been given. They are brought together for convenient reference in L. Matthiessen's ‹Grundzüge der Antiken und Modernen Algebra,› Leipzig, 1878. We proceed to give Euler's algebraic solution of the general quartic. By transforming it, bring it to the form $x^4+ax^2+bx+c=0$. Assume the general expression for a root to be $x=\sqrt{u}+\sqrt{v}+\sqrt{w}$. Squaring,

$$x^2-u-v-w=2\sqrt{u}\sqrt{v}+2\sqrt{u}\sqrt{w}+2\sqrt{v}\sqrt{w}.$$

Squaring again and simplifying,

$$x^4-2x^2(u+v+w)-8x\sqrt{u}\sqrt{v}\sqrt{w}$$
$$+(u+v+w)^2-4(uv+uw+vw)=0.$$

Equating coefficients of this and the given quartic we have

$$a=-2(u+v+w),\quad b=-8\sqrt{u}\sqrt{v}\sqrt{w},$$
$$c=(u+v+w)^2-4(uv+uw+vw).$$

But $-(u+v+w)$, $(uv+uw+vw)$, $-uvw$ are the coefficients of a cubic whose roots are u, v, w. This cubic, called «Euler's cubic,» is

$$y^3+\frac{a}{2}y^2+\frac{a^2-4c}{16}y-\frac{b^2}{64}=0.$$

Solving it, we have the values of u, v, and w, and, therefore, the values of x. Of the eight apparent values of x, four are excluded by the relation $b=-8\sqrt{u}\sqrt{v}\sqrt{w}$. To solve the quartic by the present method we must, therefore, first solve «Euler's cubic,» called the *resolvent*. When this resolvent has a rational root, then its other two roots can be expressed in terms of square roots and the quartic can be solved algebraically without the extraction of cube roots. All methods of solving algebraically the general quartic depend upon the solution of some resolvent cubic.

Binomial equations of the form $x^n-1=0$, or more generally, of the form $x^n-a=0$, can always be solved algebraically. They possess also many interesting properties. We shall give a *trigonometric* solution and mention a few of these properties. Let $x^n=a=r[\cos(2k\pi+\theta)+i\sin(2k\pi+\theta)]$, where a may be a complex quantity, where k may be any integer, and where r and θ are known from the value of a. (See TRIGONOMETRY.) By De Moivre's theorem we obtain

$$x=\sqrt[n]{r}\left\{\cos\frac{2k\pi+\theta}{n}+i\sin\frac{2k\pi+\theta}{n}\right\}.$$

By assigning to k any n consecutive integral values we obtain n distinct values for x and no more than n, since the n values recur in periods. These values are the roots required.

Among the properties of $x^n-1=0$ are the following: It has no multiple roots; if r is a root, then any positive integral power of r is a root; if m and n are relatively prime, then $x^m-1=0$ and $x^n-1=0$ have no roots in common, except 1; if h is the highest common factor of m and n, then the roots of $x^h-1=0$ are common to $x^m-1=0$ and $x^n-1=0$; if r is a complex root of $x^n-1=0$, n being a prime number, then $1, r, r^2, \ldots, r^{n-1}$ are the roots; the roots of $x^m-1=0$ and $x^n-1=0$ satisfy the equation $x^{mn}-1=0$; $x^n-1=0$ has always *primitive* roots, *i.e.*, roots which are not also roots of unity of a lower degree than n. For the proofs consult Burnside and Panton, ‹Theory of Equations,› vol. I. The theory of roots of unity is closely allied with the problem of inscribing regular polygons in a circle, or the theory of the «division of the circle» Consult P. Bachmann, ‹Kreistheilung,› Leipzig, 1872.

Solution by Approximation.—Of the various methods which have been given for the solution of numerical equations, the most satisfactory, all things considered, is the one known as «Horner's method.» It is commonly used for finding *incommensurable* roots (*i.e.*, such as involve an interminable decimal which is not a repeating decimal), but it may be used also for finding *commensurable* roots (*i.e.*, such as are integers or rational fractions). It is desirable here to begin with the theorem that *a rational fraction cannot be a root of an equation of the nth degree with integral coefficients, the coefficient of x^n being unity.* To prove this, let, if possible, $\frac{h}{k}$ be a root of $f(x)=0$, where h and k are integers and $\frac{h}{k}$ a fraction reduced to its lowest terms, and where $a_0=1$. Substitute $\frac{h}{k}$ for x, then multiply both members of the equation by k^{n-1}, and we obtain, after transposing, $\frac{h^n}{k}=-a_1h^{n-1}-a_2h^{n-2}k-\ldots-a_nk^{n-1}$. This equation is impossible, since a fraction in its lowest terms cannot equal an integer. Hence $\frac{h}{k}$ cannot be a root. This being the case, it follows that all commensurable roots are exact divisors of a_n, for a_n is numerically the product of all the roots. We know that if (fx) is divisible by $x-r$, without a remainder, r is a root. Hence we are enabled to find all commensurable roots of numerical equations of the type now under consideration by testing in succession each factor of a_n. For instance, in the equation $x^3+8x^2+13x+2=0$ the factors of a_n are ±1 and ±2. Taking the factor -2, we find that $f(x)$ is exactly divisible by $x+2$. The test for each of the three other factors yields a remainder. Hence -2 is the only commensurable root.

Before we can apply Horner's method we must know the first significant figure of the root to be found. In other words, we must «locate» the root. This can always be done by Sturm's theorem, but usually the following theorem is more convenient. *If two real numbers a and b, when substituted for x in $f(x)$, give to $f(x)$ contrary signs, an odd number of roots of the equation $f(x)=0$ lies between a and b.* Thus, to locate the roots of $x^3-3x^2-46x-71=0$, substitute for x, in succession, the values -6, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. It is found that $f(-5)$ and $f(-4)$, $f(-2)$ and $f(-1)$, $f(8)$ and $f(9)$ are pairs of values of $f(x)$ having opposite signs. As there are three roots in all, we conclude that there is just one root between each of the pairs of values -5 and -4, -2 and -1, 8 and 9. To reduce the number of trials in more difficult examples, there are theorems on the upper and lower limits of roots which may be applied.

Horner's method consists of successive transformations of an equation. Each transformation diminishes the root by a certain amount. If the required root is 1.955, then the root is diminished successively by 1, .9, .05, .005. Synthetic division is employed. Suppose we desire to find, to three decimals, the root between -1 and -2 in the above example. It is convenient first to transform the equation so that the root becomes positive. We get $x^3+3x^2-46x+71=0$. The first significant figure in the root is 1. To diminish the roots by 1 we perform by synthetic division the following operation:

1 + 3	−46	+71	1
1	+ 4	−42	
4	−42	+29	
1	+ 5		
5	−37		
1			
6			

The transformed equation, whose root under consideration now lies between 0 and 1, is $x^3+6x^2-37x+29=0$. This root being less than unity, x^2 and x^3 are less than x. Neglecting x^3 and $6x^2$, we obtain an approximate value for x from $-37x+29=0$, viz., $x=.7$. As in the process of ordinary long division or in the extraction of roots, so here the digit obtained by the first approximate division may be too large or too small and may need correction. An error of this sort will reveal itself later in the attempt to find the third digit of the root. Such correction is needed here. Actually $x=.9$. Diminish the roots of the last transformed cubic by .9, then find the third digit by the process just indicated for finding the second digit, then diminish the roots again, and so on. The entire operation is as follows:

1 + 3	−46	+71	1.055
1	4	−42	
4	−42	+29	
1	5	−27.711	
5	−37	+ 1.289	
1	6.21	− 1.166625	
6	−30.79	+ .122375	
.9	7.02		
6.9	−23.77		
.9	.4375		
7.8	−23.3325		
.9	.4400		
8.7	−22.8925		
.05			
8.75			
.05			
8.80			
.05			
8.85			

The broken lines indicate the conclusion of the successive transformations. For advanced reading on the solution of numerical equations consult E. McClintock in 'Am. Jour. of Maths.,' vol. XVII, pp. 89–110; M. E. Carvallo, Résolution numérique complète d. Equations algébriques ou transcendantes,' Paris, 1896; Karl v. Mor, 'Anwendung der Horner'schen Methode zur Berechnung der imaginären Wurzeln numerischer Gleichungen,' Innsbruck, 1884.

Multiple Roots.—Suppose that in $f(x)=0$ there are m multiple roots; that is, m roots are equal to each other. Then $f(x)=(x-r)^m\phi(x)$, and the first derivative is $f'(x)=(x-r)^m\phi'(x)+m(x-r)^{m-1}\phi(x)$. The fact that $f(x)$ and $f'(x)$ have the factor $(x-r)^{m-1}$ in common suggests the following rule for the discovery of multiple roots: Find the highest common factor of $f(x)$ and $f'(x)$. If that factor is $(x-r)^s$, then r occurs as a root $s+1$ times. If the highest common factor is $(x-r)^s(x-r_1)^t$, then r occurs as a root $s+1$ times and r_1 occurs $t+1$ times. If $f(x) \equiv 8x^3 - 20x^2 + 6x + 9$, then $f'(x) \equiv 24x^2 - 40x + 6$, and the H.C.F. is $2x-3$. Hence $\frac{3}{2}$ is a double root.

Elimination.—Take the equations,

$$f(x) \equiv x^2 + a_1x + a_2 = 0,$$

$$F(x) \equiv x^2 + b_1x + b_2 = 0,$$

and let r_1 and r_2 be the roots of the second equation. The necessary and sufficient conditions that the two equations shall have a root in common is that $f(r_1)$ or $f(r_2)$ shall vanish; that is, that the product $f(r_1) \cdot f(r_2)$ shall be zero. Multiplying together,

$$f(r_1) \equiv r_1^2 + a_1r_1 + a_2,$$

$$f(r_2) \equiv r_2^2 + a_1r_2 + a_2,$$

we get

$$r_1^2r_2^2 + a_1(r_1r_2^2 + r_1^2r_2) + a_2(r_1^2 + r_2^2) + a_1^2r_1r_2 + a_1a_2(r_1 + r_2) + a_2^2.$$

Expressing the symmetric functions of r_1 and r_2 in terms of the coefficients of the second of the given equations, we get $r_1^2r_2^2 = b_2^2$, $r_1r_2^2 + r_1^2r_2 = -b_1b_2$, $r_1^2 + r_2^2 = b_1^2 - 2b_2$, $r_1r_2 = b_2$, $r_1 + r_2 = -b_1$. Substituting these values, we have $b_2^2 - a_1b_1b_2 + a_2b_1^2 - 2a_2b_2 + a_1^2b_2 - a_1a_2b_1 + a_2^2$.

This expression, involving the coefficients of the two given equations, is called the *eliminant* or *resultant*. Its vanishing is the condition that these equations have a root in common. More generally, if from n equations with $n-1$ variables we eliminate the variables and obtain an equation $R=0$, involving only the coefficients, the expression R is called the *eliminant* or *resultant* of the given equations.

In the above example the elimination was performed with the aid of symmetric functions. Of other methods of elimination the best known are those of Euler, Bezout, and Sylvester. We outline the last, known as Sylvester's Dialytic Method. To eliminate x between

$$f(x) \equiv a_0x^n + a_1x^{n-1} + \ldots + a_n = 0,$$

$$F(x) \equiv b_0x^m + b_1x^{m-1} + \ldots + b_n = 0,$$

multiply the first successively by $x^0, x', x^2, \ldots, x^{m-1}$, and the second successively by $x^0, x', x^2, \ldots, x^{n-1}$, and we obtain $m+n$ equations. The highest power of x is $m+n-1$. If $f(x)=0$ and $F(x)=0$ have a common root, it will satisfy all the $m+n$ equations. If the different powers of x, viz., $x, x^2, \ldots, x^{m+n-1}$, be taken as $m+n-1$ unknown quantities, satisfying $m+n$ linear equations, a relation will exist between the coefficients. This condition of consistency is the vanishing of the resultant. This resultant Sylvester expresses neatly in the form of a determinant. (See DETERMINANTS.)

Discriminants.—It has been shown that a multiple root of $f(x)=0$ is also a root of $f'(x)=0$. But the condition that these two equations have a common root is expressed by the vanishing of the resultant.

The resultant of $f(x)=0$ and $f'(x)=0$ is called the *discriminant* of $f(x)=0$. It may be otherwise defined as the simplest function of the coefficients, or of the roots, whose vanishing signifies that the equation has equal roots.

FLORIAN CAJORI,
Professor of Mathematics, Colorado College.

Equator, an imaginary great circle of the celestial vault or on the surface of the earth. As used in astronomy the term signifies a great circle of the celestial vault at right angles to its axis, and dividing it into a northern and a southern hemisphere. It is constituted by the plane of the earth's equator, produced in every direction till it reaches the concave of the celestial sphere. The sun is twice a year in the celestial equator—namely, at the equinoxes, whence the equator is also known as the equinoctial line, or simply the equinoctial (see EQUINOX). The point in the equator which touches the meridian is raised above the true horizon by an arc which is the complement of the latitude. The sun and planets all have equators. They rotate around their several axes, and the plane at right angles in each case is the equator of the heavenly body. In geography, the equator is a great circle on the surface of the earth equidistant from its poles, and dividing it into two hemispheres. Its latitude is zero; it is therefore marked on maps as 0. Other parallels of latitude are counted from it, augmenting in their numerical designation as their distance from it north or south increases, the poles being 90°. The plane of the terrestrial equator is a plane perpendicular to the earth's axis and passing through its center. The magnetic equator is a somewhat irregular line, nearly but not quite a great circle of the earth, in which there is no dip of the magnetic needle. It is hence called also the aclinic line. It is inclined to the horizon at an angle of 12°, and cuts it at two points almost exactly opposite to each other, the one in the Atlantic and the other in the Pacific. It is not far from the geographical equator, but its situation slowly alters year by year, there being a slow oscillation of the magnetic poles, while the geographical equator and poles are fixed.

Equato'rial («of the equator»), a geographical and astronomical term. In astronomy it is usually applied to a telescope so mounted as to have a motion in two planes at right angles to each other; one parallel to the axis of the earth, and the other to the equator. Each axis has a graduated circle, one for measuring declination and the other right ascension. Clockwork is sometimes attached to the instrument to give the motion in right ascension, and thereby keep the object constantly in the field of the instrument. See ASTRONOMY.

Equatorial Coudé («Elbow Equatorial»), a form of equatorial telescope invented by Loewy, of the Paris Observatory. The observer can remain stationary in a comfortable position, with a desk-table built around the eye-piece end, and can have all this part enclosed from the cold, and warmed if desired, at the same time commanding the whole heavens without rising from his chair. See ASTRONOMY; TELESCOPE.

Equatorial Current. See CURRENTS, *Marine*

Equerry, ĕk'wĕ rĭ or ē-quer'ĭ, an officer of the royal household of Great Britain in the department of the master of the horse. There are six equerries, who are in attendance monthly, one at a time, their principal duty being to precede the sovereign in a coach, when the ruler rides abroad in state. The clerk-marshal, as the chief equerry is styled, has a salary of £500 per annum, and the equerries in ordinary £300.

Equestrian Order, or **Equites,** the order of knights in ancient Rome. The equites or knights originally formed the cavalry of the army. They are said by Livy to have been instituted by Romulus, who selected 300 of them from the three principal tribes. Soon after the first Punic War the equites became a distinct order in the state, and the juries and the farmers of the revenue were selected from their ranks. They held their position in virtue of a certain property qualification, and toward the end of the republic they possessed much influence in the state. They had particular seats assigned to them in the circus and theatre, and the insignia of their rank, in addition to a horse, were a gold ring and a tunic with two narrow purple stripes. Their privileges were curtailed by Sulla and under the later emperors the order disappeared from the stage of political life.

Equidæ, ĕk'wĭ-dē, the horse family, the most highly specialized of the perissodactyl ungulates, characterized by the fact that only one toe (the third) in each foot is now functional, traces ("the splint bones") remaining of the two other toes (the second and fourth) in the "splint bones" hidden beneath the flesh on each side of the shank of the foot. (For the relationships of this family to the titanotheres, tapirs, and rhinoceroses, see UNGULATA; and for the evolution of the characteristic foot-structure see HORSE, EVOLUTION OF.) The family contains but a single genus (*Equus*), structural distinctions not being of sufficient importance to separate generically the modern horses from several extinct species, or from the asses or zebras, or these from each other. Apart from the dependence upon a single toe, the family is characterized by the facts that the orbit is completely surrounded by bone; the incisor teeth are chisel-shaped; the canines or "tushes" are rudimentary (when present), and the premolars (except the first or "wolf tooth") resemble the hypselodont molars. Externally the members of this family are robust, with comparatively slender limbs, the feet "booted" in a single horny hoof, encasing the terminal phalanx; the body thickly clothed with short close hair, which, however, becomes longer, and in some species profuse, forming a mane, on the nape and tail. The colors are apt to be disposed in dark stripes on a yellow or brownish ground, most strikingly in the zebras, but traceable in most others. There are never any horns, and speed is depended on to escape from enemies which cannot be beaten off by kicking with the hind feet, while struggles between rival males for the leadership of the bands of mares are carried on mainly by biting and striking with the fore feet. The fore-limbs, or both pairs, have a callous pad upon the inside, "which," says Beddard, "is possibly to be looked upon as an aborted gland, probably originally of use as secreting some odorous substance calculated to enable strayed members of the herd to regain their companions." The whole structure of the equidæ has been developed in adaptation to a life upon open dry plains, where ability to travel with rapidity and to live upon grass and herbage has been perfected to a high degree. The stomach has no such complicated arrangement for the assimilation of this comparatively innutritious diet as has been acquired by the ruminants (q.v.). The alimentary canal is of great length (about eight times the length of the body); and the stomach, simple in form, is divided into a cardiac, and a pyloric part, sharply distinguished by the dense epithelium lining of the former. The cæcum is twice as large as the stomach, and there is no gall-bladder. The teats are two in number and situated in the groin. One or two foals are produced at a birth after a gestation of about 11 months. All the species are gregarious and polygamous: and like most such animals are readily tamable, though the zebra has proved somewhat intractable and useless to mankind.

The family in the course of its history has occupied all the larger land-areas of the globe except Australia; but although its ancestors abounded in both Americas in the past, and modern horses run wild have multiplied and flourished exceedingly upon their grassy plains, no living species inhabited the New World. In the Old World the horse or horses and one of the asses were Asiatic and European; a second species of ass and the various zebras were wholly African. See ASS; HORSE; QUAGGA; ZEBRA.

Equilib'rium, a state of equipoise, produced by the mutual counteraction of two or more forces; as the state of the two ends of a lever or balance when both are charged with equal weight. Equilibrium is characterized by three phases. When a body suspended by a string, for example, on being slightly moved out of any position, always tends to return to its position, that position is said to be one of *stable equilibrium;* when a body like a stick or other object balanced on its point will not thus return to its previous position, its position is said to be one of *unstable equilibrium;* and when a body such as a sphere resting upon a horizontal plane will rest in any position in which it is placed, it is said to be of *neutral* or *indifferent equilibrium.*

Equilibrium, in physiology, the ability to maintain the body by proper muscular force under nervous control, so that it can perform co-ordinated movements, or resist the force of gravity. By equilibrium is here meant the control of the body in the upright position, apart from the localized processes of co-ordination. Loss of equilibrium shows itself particularly in walking and running. Here the centre of gravity of the body is constantly changing and the ability of the individual to hold himself erect depends upon a number of features. The eye, the tactile sense of the feet, the joint-senses, the muscular sense that weighs the various muscular movements, and the higher cerebral centres are all involved, and loss of equilibrium or inco-ordination may result from disease or injury to any of these functions. Loss of eyesight does not necessarily involve any loss of equilibrium, but loss of tactile sense of the feet, such as is seen in locomotor ataxia, or in people who have had their feet frozen, almost invariably produces a loss of equilibrium. In the same disease (locomotor ataxia), and in forms of neuritis, the loss of muscular sense and joint-sense produces similar phenomena. For the higher cerebral centres of control there is good reason to believe that the semicircular canals in the internal ear constitute a special sense-organ for the determination of the direction of the movements of the head which are so essential in the preservation of general equilibrium. Diseases of the semicircular canals are frequently accompanied with dizziness and vertigo. It also seems probable that certain areas in the cerebellum are closely associated with the equilibrium. See CEREBELLUM; INCO-ORDINATION; LOCOMOTOR ATAXIA; SEMICIRCULAR CANALS.

Equilibrium, Chemical. In mechanics a system is said to be in equilibrium when the forces that act upon it are precisely balanced, so that their resultant is everywhere zero. A system is similarly said to be in chemical equilibrium when its state is such that there is no tendency toward a sensible chemical change, in any of its parts. The absence of chemical action may be absolute, or merely apparent. In other words, there may be no chemical changes going on at all, or there may be opposite changes going on simultaneously, in such a way that no resultant modification can be observed in any part of the system, however small the part selected for observation may be. In the latter case the existence of the simultaneous and opposite reactions can only be indirectly inferred from a study of the system when it is not in equilibrium.

According to the theory of chemical affinity that was held before the importance of mass-action was understood, two substances either would combine or would not, according as their "affinities" were more or less completely satisfied in the combined state, or in the uncombined state. That this view is entirely inadequate to explain the facts of chemistry is made evident by the following simple example: When steam is passed over red-hot iron filings, it is decomposed into oxygen and hydrogen, the iron absorbing the oxygen with the formation of oxide of iron, while the hydrogen escapes in the free state; but if hydrogen is passed over red-hot oxide of iron, the oxide is reduced to the metallic state, its oxygen combining with the hydrogen to produce steam, which passes on in the hydrogen current. This apparent contradiction may be best explained by assuming that when a mixture of steam and hydrogen is in contact with a red-hot mixture of iron oxide and metallic iron, both of the foregoing reactions take place simultaneously. If the metallic iron and the steam are present in excessive amounts, the resultant action will be, on the whole, the oxidation of the iron and the decomposition of the steam; while if the iron oxide and the hydrogen are present in excess, the resultant action will be the reduction of the oxide to the metallic state, and the simultaneous formation of steam. It is therefore apparent that in some reactions, at any rate, the relative masses in which the various constituents are present must be considered with much care, before any prediction of the chemical deportment of the mixture can be made. Attention was first directed to this fact by Claude Louis Berthollet ('Essai de statique chimique,' 1803). In the example cited above, if the iron, iron oxide, hydrogen, and steam were left in contact in a closed vessel, a state of apparent equilibrium would be finally attained, in which the formation and decomposition of the steam would occur with equal rapidity, so that no visible change would take place thereafter. When this state of "chemical equilibrium" is attained, the abstraction of hydrogen or of iron oxide, or the addition of steam or of metallic iron, will destroy the equilibrium, and more iron will be oxidized, until a new state of equilibrium is established. Similarly, the abstraction of steam or of metallic iron, or the addition of hydrogen or of iron oxide, when the system is in equilibrium, will be followed by the reduction of a portion of the iron oxide, and the establishment of a new state of equilibrium. According to Berthollet, all reactions are fundamentally of this kind. When sodium chloride is added to a solution of silver nitrate, we know that the silver is all thrown down in the form of an insoluble chloride. In this case, Berthollet would consider that the sodium chloride, sodium nitrate, silver chloride, and silver nitrate tend toward a state of chemical equilibrium, but that since the silver chloride is continually removed from the solution by reason of its insolubility, it is impossible for the state of equilibrium ever to be attained, just as it would be impossible for such a state to be attained in our previous illustration if one of the constituents (say the iron oxide) were removed, or rendered inactive in any way, as fast as it were formed.

The ideas of Berthollet have been found to be sound in their essentials, and they have served as the foundation stones for the modern theory of chemical action, though their full development cannot be explained without the use of the differential calculus. The basis of the theory of mass-action, so far as solutions are concerned at all events, appears to be substantially as follows: Two substances in solution cannot combine with each other, except when a molecule, or ion (see SOLUTION) of the one, in its wandering through the solution, chances to encounter a molecule or ion of the other. Now while we do not know the actual number of encounters that take place in a given time between molecules of different kinds, we do know that in a homogeneous solution the chance that any one given molecule of the first kind will encounter some molecule of the second kind within (say) the next second, is strictly proportional to the number of molecules of the second kind that are present in the solution; and conversely, the chance that any given molecule of the second kind will encounter some molecule of the first kind, within the next second is strictly proportional to the number of molecules of the first kind that are present. Since the number of molecules of each kind that are present in an actual solution is practically infinite, this amounts to saying that the actual number of encounters between molecules of different kinds, in one second, is proportional to the product of the numbers of molecules of the first and second kinds that are present. As an illustration of the usefulness of this principle, we may consider the equilibrium of a mixture of acetic acid and ethyl alcohol. Some of the acid combines with some of the alcohol to form water and ethyl-acetic ester (see ESTER), but the reaction is never complete, since a state of equilibrium is attained after a time, in which the inverse combination takes place just as fast as the direct one. The molecular weight of acetic acid ($CH_3COO.H$) is 60, that of ethyl alcohol (C_2H_5OH) is 46, that of ethyl-acetic ester or ethyl acetate ($CH_3COO.C_2H_5$) is 88, and that of water (H_2O) is 18. A mass of any substance which contains as many grams as there are units in the molecular weight of the substance is known as a «gram-molecule» of the substance. This name is rather unhappily chosen, but the idea itself is a useful one, and is commonly employed in modern writings upon theoretical chemistry. Let us suppose that one gram-molecule of acetic acid (60 grams) is originally mixed with M gram-molecules of ethyl alcohol (46M grams), and with N gram-molecules (18M grams) of water, and let us inquire what the composition of the mixture will be when the state of final chemical equilibrium has been attained. The advantage of taking the gram-molecule as the unit of mass is, that when this unit is used the number of grams of acetic acid, alcohol, and water that are originally present will be proportional to 1, M and N, and we may speak of M and N, and write them in our equations precisely as though they were really the number of actual molecules present. The acetic acid and alcohol act upon each other as indicated by the equation $CH_3COO.H + C_2H_5OH = CH_3COO.C_2H_5 + H_2O$. Now let us assume that when the state of equilibrium has been attained, X gram-molecules of the alcohol have been decomposed. This implies that X gram-molecules of the acetic acid have also been decomposed, and that X gram-molecules, each, of water and of ethyl acetate have been formed. The total numbers of gram-molecules of the various substances that are present when the final state of equilibrium is attained are therefore as follows: Acetic acid, $1 - X$; alcohol, $M - X$; water, X; ethyl acetate, $N + X$. The number of molecular collisions per second, in which a molecule of acetic acid encounters a molecule of alcohol, is therefore (in the final state) proportional to $(1 - X)(M - X)$; and since the chemical action is itself proportional to the number of such collisions, we may assume that the number of gram-molecules of ethyl acetate formed per second, in the state of equilibrium, is $A(1 - X)(M - X)$, where A is a constant whose value we do not know. The same line of reasoning shows that the number of gram-molecules of ethyl acetate that are lost from the solution, in the same time, through combining with water to reproduce acetic acid and alcohol, is $B(N + X)X$, where B is another constant, whose value is also unknown. Since the existence of equilibrium requires that the quantity of ethyl acetate present shall be constant, we have $A(1 - X)(M - X) = B(N + X)X$. Now it is known by experiment that when the original mixture is free from water, and contains chemically equivalent amounts of acetic acid and alcohol, so that $M = 1$ and $N = O$, the state of final equilibrium is attained when $X = \frac{2}{3}$. If these values of M, N and X are substituted in the foregoing equation, we find that A and B are connected by the necessary relation $A = 4B$. If we replace A by 4B and then divide through by B, the foregoing equation reduces to $4(1-X)(M-X) = (N+X)X$, or $3X^2 - (4 + 4M + N)X + 4M = O$, a quadratic equation from which the value of X (that is, the number of gram-molecules of acetic acid decomposed) may be inferred, in the final state of equilibrium, for any desired initial mixture of acetic acid, alcohol, and water. This example has been given at some length, both because it illustrates clearly the principles of chemical equilibrium and the law of mass-action, and because reactions of this very kind, in which esters are formed by the direct action of an acid upon an alcohol, have a special historic interest, since their study has contributed in no small measure toward placing the modern theory of chemical equilibrium upon a firm foundation.

When it is desired to determine the state of a chemical system after the lapse of a definite interval from an initial instant for which its state is given, we must form a differential equation in which the condition is expressed that the chemical change, per unit of time, is proportional (as above) to the product of the number of gram-molecules of the reacting substances that are present at the instant considered; and having formed this equation and integrated it, we obtain an expression in which the composition of the system is expressed as a function of the time. When several substances that may react upon one another are present, the differential equation is more complicated in form, as might be expected; but for details of this sort reference must be made to works on theoretical chemistry. When the system contains several acids and one or more bases, the distribution of the bases among the various acids may be investigated in accordance with similar principles, and by comparing the numerical results that are thus obtained with the facts of observation, estimates of the true relative «affinities» of the acids may be had.

When, as is often the case, the course of a reaction depends upon the temperature, the principles of mass-action apply as before, but regard must also be had for the laws of thermodynamics (q.v.), which usually impose certain limitations upon the equations. The full theory of chemical changes in which thermodynamical considerations play an important part was given by J. Willard Gibbs, in a paper of great power and originality entitled 'On the Equilibrium of Heterogeneous Substances,' published in the 'Transactions of the Connecticut Academy of Arts and Sciences' for 1875. This paper is exceedingly difficult reading on account of its generality, but it contains the germs of many discoveries that were made years afterward. Consult: Nernst, 'Theoretical Chemistry.'

Equine Antelope. See BLAUBOK.

Equinoc'tial, in astronomy, synonymous with equator. When the sun is on the equator there is equal length of day and night over all the earth: hence the name equinoctial. See EQUATOR; EQUINOX.

Equinoctial Gale, a gale popularly supposed to occur at the time of the spring or autumn equinox. See EQUINOX.

Equinoctial Points are the two points wherein the equator and ecliptic intersect each other; the one, being the first point of Aries, is called the vernal point; and the other, in the first point of Libra, the autumnal point. See ECLIPTIC; EQUINOX; EQUINOXES, PRECESSION OF THE.

Equinovalgus. See DEFORMITIES.

Equinovarus. See DEFORMITIES.

E'quinox, in astronomy, is that time of the year when the day and night are equal: the length of the day is then 12 hours; the sun is ascending 6 hours, and descending the same time. This is the case twice a year, in spring and in autumn, when the sun is on the equator. When the sun is in this situation the horizon of every place is divided into two equal parts by the circle bounding light and darkness; hence the sun is visible everywhere 12 hours, and invisible for the same time in each 24 hours. The vernal equinox is on 21 March, and marks the beginning of spring; the autumnal is on 23 September, which is considered the commencement of autumn; at all other times the length of the day and of the night are unequal, and their difference is the greater the more we approach either pole, and in the same latitude it is everywhere the same. On the equator this inequality entirely vanishes; there, during the day, which is equal to the night, the sun always ascends six hours and descends six hours. In the opposite hemisphere of our earth the inequality of the days increases in proportion to the latitude: the days increase there while they diminish with us, and *vice versa.* The points where the ecliptic intersects the equator are called equinoctial points. The vernal equinoctial point was formerly at the entrance of the constellation of Aries; hence the next 30 degrees of the ecliptic, reckoned eastward from it, have been called Aries; but this point long ago deserted the constellation of Aries, and now stands in Pisces; for it is found by observation that the equinoctial points, and all the other points of the ecliptic, are continually moving backward or westward; which retrograde motion of the equinoctial points is what is called the precession of the equinoxes. It appears from the result of calculations that the path of either of the poles is a circle, the poles of which coincide with those of the ecliptic, and that the pole will move along that circle so slowly as to accomplish the whole revolution in about 25,800 years nearly. The diameter of this circle is equal to twice the inclination of the ecliptic to the equator, or about 47°. Now, as the ecliptic is a fixed circle in the heavens, but the equator, which must be equidistant from the poles, moves with the poles, therefore the equator must be constantly changing its intersection with the ecliptic. And from the best observations it appears that the equator cuts the ecliptic every year 50.25″ more to the westward than it did the year before; hence the sun's arrival at the equinoctial point precedes its arrival at the same fixed point of the heavens every year by 20 minutes 23 seconds of time, or by an arc of 50.25″. Thus, by little and little, these equinoctial points will cut the ecliptic more and more to the westward, till, after 25,800 years, they return to the same point. See DAY; ECLIPTIC; EQUATOR.

Equinoxes, Precession of the, the motion of the equinoxes along the ecliptic due to the change in the direction of the earth's axis of rotation, caused by the attraction of the moon and sun on the protuberant equatorial ring of the earth. See EQUINOX.

Equiseta'ceæ. See *Equisetales* under FERNS AND FERN ALLIES.

Equise'tum. See *Equisetales* under FERNS AND FERN ALLIES.

Equites, ĕk'wĭ-tēz. See EQUESTRIAN ORDER.

Equity is "that system of justice which was administered by the high court of chancery in England in the exercise of its extraordinary jurisdiction." Bispham, 'Principles of Equity.'

In England, prior to the American Revolution, the courts were divided into courts of law and courts of equity. In the law courts the parties were compelled to proceed strictly according to the law and the practice, and the forms of pleading were so intricate that many cases were decided on the pleadings without the merits of the case ever being heard; and often when the cause was heard it was impossible to administer justice on account of the form of action, the parties to the action, and the cause of action on which suit had been brought. In the courts of equity they were not restricted by the technical pleadings; amendments could more readily be granted; the parties to the action could be changed by either dropping some or adding others; and the decree could be framed to meet the particular question involved, so that justice would be done to all the parties interested.

After the Revolution the States adopted the English system; but while some of them have kept strictly to that system and have had distinct courts of law and of equity, other States have law and equity administered by the same judges and courts, at one time sitting as courts of law and at another time as courts of equity.

Some of the rules and maxims of equity are: "Equity considers that as done which ought to be done." "Equity acts *in personam.*" "He who comes into equity must do so with clear hands." "Between equal equities priority of time will prevail." "Between equal equities the law will prevail." "No right without a remedy." "When a court of equity has once acquired jurisdiction of a cause it will continue to act until the matter is finally disposed of."

Equity is divided into three great classes or divisions: Equitable titles, equitable rights, and equitable remedies. Equitable titles are those which are recognized only by a court of equity, as where, when a person gave value for a chose in action which was assigned to him, the assignment was not recognized at law, as it would violate the rules against champerty and maintenance, but equity allows the assignee to bring suit in the name of the assignor. Equitable rights arise where a guardian enters into a transaction with his former ward a very short time after the ward has obtained his majority. If within a reasonable time the ward returns what he received from the guardian the guardian will, in equity, be compelled to return the property to the ward. Equitable remedies arise in those cases in which the law recognizes a right but cannot enforce it, as where a contract is made for the sale of a piece of property, if the seller refuses to convey, the purchaser's remedy at law is for damages for breach of the contract; but in equity the court will decree specific performance. Generally this applies only to real estate, because if it is personal property, after the damages are recovered other personal property of the same kind can be purchased; but if the personal property is of such nature that it cannot be duplicated, such as a painting by a particular artist, equity will affirm relief in the way of specific performance.

Suits in equity are commenced by a bill or petition. The bill may be amended, or, if the proceeding have gone too far for that, a supplemental bill may be filed. The defense is by demurrer, plea, or answer. The judgment of the court is called a decree, and the relief granted is such as to affect all the parties, and is adapted to the facts and circumstances of that particular case. The general rules of evidence are the same as in a proceeding at law, but the answer to the bill, if made under oath, is evidence for the defendant in so far as it is responsive to the bill.

Equity, Courts of. See COURT.

Equity of Redemption. Upon a mortgage, although the estate, upon non-payment of the money, becomes vested in the mortgagee, yet equity considers it only a pledge for the money, and gives the party a right to redeem, which is called his equity of redemption. If the mortgagee is desirous to bar the equity of redemption he may oblige the mortgagor either to pay the money or be foreclosed of his equity, which is done by proceedings in chancery by bill of foreclosure. See CHANCERY; EQUITY; FORFEITURE; MORTGAGE; REDEMPTION.

Equiv'alent, having equal value, power, area, or volume. As the quantities by weight of bodies which combine with hydrogen, oxygen, and one another are fixed, there is always one simplest proportion in which they can be regarded as combining with or substituting one another. This quantity was called by Dalton the atomic weight, because he considered these proportions as the comparative weights of the atoms, or ultimate particles of the bodies. The term, however, was regarded as hypothetical, and both combining proportion and equivalent were proposed instead. The latter, which was suggested by Dr. Wollaston, was accepted, and was till quite recently applied to elements and compounds. It has been shown, however, that quantities were thus styled equivalent which were not so in any sense of the term. Thus, while one part by weight of hydrogen combines with 8 of oxygen, and 8 of oxygen with 14 of nitrogen, this quantity of nitrogen combines not with 1 but with 3 of hydrogen. Strictly, therefore, the quantity of nitrogen equivalent to 1 of hydrogen is $4\frac{2}{3}$. The older equivalent notation was consequently irregular and unsystematic,— equivalents being used in some cases but not in others. Hence has arisen the modern use of the word, in which it is expressly distinguished from the combining proportion or atomic weight. The latter is the number which best denotes the proportion in which the substance reacts chemically with all other bodies, and which is fixed by reference not to mere proportional weight, but also to vapor density, specific heat, crystalline form, diffusion, etc.; physical phenomena, in which certain relations are so constant that they presumably indicate natural laws. The former simply denotes the proportion by weight in which a body combines with or replaces a unit of hydrogen. See CHEMISTRY.

Equuleus, ĕ-kwoo'lē-ŭs, in astronomy («the Colt» or «Little Horse»), one of the 48 original constellations of the Almagest, situated just between the head of Pegasus and Delphinus. It has Aquarius on its south side. It is a very inconspicuous constellation, its brightest star being of the fourth magnitude. Also a name given to the rack, or instrument of torture.

Era. See CHRONOLOGY; EPOCH.

Era of Good Feeling, 1817–23. In American political history, Monroe's two administrations, up to the canvass for his successor. There were practically no issues, and but one party. The issue on which the Federalist party was founded had long since been appropriated by the Democrats, and it had foolishly taken theirs in exchange; the embargo and the war had created a sectional issue, but the peace ended that and left absolutely no pretext for division. The Hartford Convention (q.v.) had killed the old leaders politically; the new ones had joined the Democrats, because the embargo and the war had driven New England capital from commerce into manufactures, and it wished to demand tariff favors from the administration. But it was a decade before the tariff and internal improvements, the next division lines, assumed theoretic consistency. Monroe issued an inaugural in 1817 especially to placate the Federalists; and followed it by a tour through New England where he was received with immense ovations from both parties. He was unanimously re-elected in 1820, save for the whim of one elector who did not object to him. The personal factions which contested the field in 1824, the coalition (q.v.) which decided the result, and the Jacksonians' fury over it, effectually ended the good feeling.

Eragros'tis, a large genus of the grass family, represented in America by about 30 species, either native or naturalized. The species are from a few inches to several feet in height, and are found in nearly all parts of the United States. None are of commercial importance, and such as are used for hay are accidental growths among cultivated grasses. The strong-scented eragrostis (*E. major*), is an ill-smelling grass, but tall, erect, and rather handsome, owing to the shape and size of its leaves. It is found in almost every part of the United States and Ontario, naturalized from Europe.

Erard, ā-rär, **Sebastien,** French musical instrument maker: b. Strasburg 5 April 1752; d. Passy, near Paris, 5 Aug. 1831. He went to Paris at 18, and with his brother, Jean Baptiste, produced pianofortes so superior to any previously made in France that his fame quickly spread, and orders flowed in upon him from all quarters. During the Revolution he went to England and established a manufactory in London, and when peace was restored his life was passed between that city and Paris. His improvements upon the harp, more especially that of the double movement, the principle of which he afterward communicated to the piano, entitle him to high merit as an inventor.

Erasistratus, ĕr-a-sĭs'tra-tŭs, Greek physician. He lived in the 3d century before the Christian Era. He was the court physician of Seleucus Nicator, king of Syria, and rendered himself famous by the sagacity with which he discovered the malady of Antiochus, the king's son. He subsequently went to Alexandria, where he devoted himself to the study of anatomy. He was the first who systematically dissected the human body, and his description of the brain and nerves is much more exact than any given by his predecessors. He classified the nerves into nerves of sensation and of locomotion, and it is said had almost stumbled upon the discovery of the circulation of the blood. He was remarkably averse to blood-letting and the giving of purgatives, relying chiefly upon diet and regimen, bathing, exercise, friction, and the most simple articles of the vegetable kingdom, for the restoration and preservation of health. He wrote several works on anatomy, practical medicine, and pharmacy, of which only the titles remain, together with a great number of short fragments preserved by Galen and other ancient medical writers.

Erasmus, ĕ-răz'mŭs, **Saint,** Syrian bishop and martyr. He was put to death under Diocletian by disemboweling, and his martyrdom is frequently represented in art. As he was counted as one of the 14 Succorers of the Distressed, so was his aid especially invoked in affections of the stomach. The remaining 13 Succorers are Saints Acasius, Blasius, Christopher, Cyriacus, Dionysius the Areopagite, Egidius, Eustathius, George the Martyr, Pantaleon, Vitus, Barbara, Catharine, and Margaret.

Erasmus, Desiderius, Dutch scholar: b. Rotterdam probably 28 Oct. 1467; d. Basel, Switzerland, 12 July 1536. He was the illegitimate son of one Gerhard of Gouda. The name by which he is known is merely the Latin and Greek rendering of Gerhard, Desiderius the Latin, and Erasmus, or, more correctly, Erasmius, the Greek equivalent. He was a singing-boy in the Cathedral of Utrecht till his 9th year, then entered the school at Deventer, where he displayed such brilliant powers that it was predicted that he would be the most learned man of his time. At the age of 17 he assumed the monastic habit, but the bishop of Cambray delivered him from this constraint by taking him as a secretary. In 1492 he traveled to Paris to perfect himself in theology and polite literature, and there became the instructor of several rich Englishmen, from one of whom — Lord Montjoy — he received a pension for life. He accompanied them to England in 1497, where he was graciously received by the king. He returned soon after to Paris, and then traveled into Italy to increase his stock of knowledge. He now asked a dispensation from the vows of his order, which the Pope granted him. He visited Venice, Padua, and Rome; but brilliant as were the offers here made him, he preferred the invitation of his friends in England. When he visited the lord-chancellor, Sir Thomas More, without making himself known to him, the chancellor was so delighted with his conversation that he exclaimed, "You are either Erasmus or the devil." He was offered a benefice, but was unwilling to fetter himself by an office of this kind. He was for a short time professor of Greek at Oxford. He afterward traveled through Germany and the Netherlands, and went to Basel, where he had his works printed by Froben.

To profound and extensive learning Erasmus joined a refined taste and a delicate wit. Naturally fond of tranquillity and independence, he preferred the pleasure of literary ease and retirement to the pomp of high life. His caution and worldly prudence offended many of the best men of his times, but he did great and lasting service to the cause of the revival of learning. Like many notable men of his day who recognized the need of reforming ecclesiastical abuses, he sympathized with the beginnings of the Reformation, but repudiated it when it went to the excess of rebellion. He wished for a general ecclesiastical council, to be composed of the most learned and enlightened men, but had not the satisfaction of seeing his wish accomplished. What he did to serve the world was effected by his writings, which will always be prized for their interesting matter and graceful style. Besides his editions of various classics, the first edition of the Greek Testament from MSS. (with Latin translation), and his other philological and theological writings, may be only mentioned his well-known book in praise of folly 'Encomium Moriæ,' and his 'Colloquies.' His letters are very valuable in reference to the history of that period. See Lives by Knight (1726); Jortin (1748); Burigny (1752); Durand de Laur (1874); Feugère (1874); Drummond (1873); Froude (1894).

Eras'tians, in England, a name applied to a party that arose in the 17th century, denying the right of autonomy to the Church — a right neither maintained nor denied by Erastus. The Erastian controversy broke out at the time of the Westminster Assembly. The leading Erastians in that assembly were Lightfoot and Coleman, who were supported by Selden and Whitelocke in the House of Commons. Since the time of the Reformation the controversy has been confined chiefly to the Church in Scotland.

Eras'tus, Thomas (properly LIEBLER or LIEBER), German theologian and physician: b. Auggen, near Mühlheim, 1524; d. Basel, Switzerland, 1583. He studied theology at Basel (where he Grecized his name), and philosophy and medicine at Bologna and Padua. After nine years in Italy, he was appointed physician to the counts of Henneberg; then professor of medicine at Heidelberg, and court-physician to the elector palatine. He removed from Heidelberg to fill the chair of medicine at Basel in 1580. Shortly before his death he had been appointed professor of ethics. Erastus was a skilful physician and a man of upright character, an equally vigorous writer against "the new medicine of Philip Paracelsus" (1572) and in favor of the burning of witches (1577 et seq.). In theology he was a follower of Zwingli, and his fame now rests on his strenuous opposition to Calvinist discipline and Presbyterian order. Erastus was excommunicated on a false suspicion of heresy, founded on a correspondence with Unitarians of Transylvania, but was restored in 1575. His chief work is a treatise on excommunication entitled: 'Explicatio gravissimæ quæstionis utrum Excommunicatio . . . mandato nitatur divino, an excogitata sit ab hominibus.' This was answered by Beza in his 'De vera Excommunicatione et Christiano Presbyterio' (1590). Erastus maintained that no member of the Church should be excluded from her communion as a punishment for sin. Punishment is "the special duty and office" of the civil magistrate. See Bonnard, 'Thomas Eraste et la discipline ecclésiastique' (1894).

Erato, ĕr'a̤-tō (Gr. *eraō,* I love), one of the nine Muses, whose name signifies loving, or lovely. She presides over the songs of lovers, and touches, as Ovid, in his 'Art of Love,' informs us, the hearts of the coldest maidens by her tender lays. (See MUSES.) Erato is also the name of one of the planetoids.

Eratosthenes, ĕr-a̤-tŏs'thē-nēz, Alexandrian astronomer, geographer, and philosopher: b. Cyrene, Africa, 276 B.C.; d. about 196 B.C. He became librarian at Alexandria, and improved the science of mathematical geography, which he reduced to system, but gained his greatest renown by his investigations of the size of the earth, his estimate of the circumference of which was surprisingly near the truth. He wrote also on chronology, grammar, etc. and was considered no mean poet. He rendered much service to astronomy and first observed the obliquity of the ecliptic. He is said to have starved himself to death after becoming blind. The extant fragments of his writings were collected by Bernhardy in his 'Eratosthenica' (1822); his geographical fragments were published by Berger in 1880.

Er'ben, Henry, American naval officer: b. New York September 1832. He was graduated at the United States Naval Academy in 1854; became commander in 1868; rear-admiral in 1894; and was retired in the latter year. During the Civil War he served with Admiral Farragut in the Gulf of Mexico and on the Mississippi River with Admiral Dupont, etc. In 1866–9 he was on duty in South America; later, in command of the Tuscarora, he made deep-sea soundings in the Pacific; afterward commanded the Pensacola in a trip round the world; and in 1891–2 was commandant of the New York Navy Yard.

Er'bium, a rare metallic element, occurring in the form of a tantalate or silicate in the minerals gadolinite, fergusonite and euxenite, and as a phosphate in the mineral xenotime. It has the chemical symbol Er, or E, and an atomic weight of about 166. The oxide of erbium, Er_2O_3, has a pale rose color, is infusible, and, when strongly heated glows with a brilliant green light. It is not affected by water, but dissolves slowly in hot acids with the formation of the corresponding erbium salts. Most of the salts are rose-colored, and the haloid compounds are also deliquescent. The name erbium is derived from Ytterby, Sweden, where the mineral gadolinite is found. The recognition of erbium as a new element is attributed to Mosander (1843); but the metal itself has not yet been isolated.

Er'cildoune, Thomas of (called the Rhymer, and Learmont), a Scottish poet and seer, who flourished probably between 1220 and 1297, and wrote a poem called 'Sir Tristrem.' He occupies a very conspicuous position in the annals of Anglo-Saxon literature, but not very much is known of his life, and there is even some dispute respecting his authorship of various pieces attributed to him.

Ercilla y Zuniga, ār-thēl'yä ē thoo-yē'gä, **Alonzo de,** Spanish soldier and poet: b. Madrid 7 Aug. 1533; d. there 29 Nov. 1594. An insurrection breaking out among the Araucanians, a tribe of Indians on the coast of Chile, Ercilla joined an expedition sent against them. The difficulties the Spaniards had to encounter, the heroic resistance of the natives, and the multitude of gallant deeds by which the war was signalized, inspired the young and brave Ercilla with the idea of making it the subject of an epic poem, to which he gave the name of 'La Araucana.' He returned to Spain after having finished the first part of his epic. In 1570 he married Maria Bazan at Madrid, whose charms and virtues are celebrated by him in various passages of his poem. In 1569 the first 15 cantos of his poem, in 1578 a second, and in 1590 a third part were added, making in all 37 cantos; he did not live, however, to complete the work, but died in great poverty and obscurity. The 'Araucana' is an historical epic in the octave measure, in which the author confines himself, with the exception of some episodes and a few fictions, to the exact historical course of events. Hence the poem often assumes almost the character of a chronicle. Lope de Vega has taken from the epic of Ercilla the materials for his piece 'Arauca Conquered.' The best editions are those published at Madrid in 1776 and 1828. It has been translated into Italian, and twice into French. See ARAUCANIANS.

Erckmann-Chatrian, ĕrk'män - shä-trē-äṅ', the combined surnames of two Frenchmen, natives of Alsace, who collaborated in writing romances. EMILE ERCKMANN: b. Phalsbourg 20 May 1822; d. Paris 14 March 1899. Having completed his studies in the communal college of his native town, he went to Paris in 1842 to study law. Returning to Phalsbourg in 1847 because of a serious illness, he began to turn his attention to romance writing during his convalescence. It was about this time (1848) that he met his collaborateur, LOUIS GRATIEN CHARLES ALEXANDRE CHATRIAN, b. Soldatenthal 18 Dec. 1826; d. Raincy 5 Sept. 1890. Chatrian's father was a glass-blower, and it was intended that he should follow the same craft. Instead of doing so, however, he left his native village and became a teacher in Phalsbourg, where he made the acquaintance of Erckmann. For several years the stories produced by this co-partnership were published in obscure newspapers, both in Strasburg and Paris, but about 1860 their graphic romances of eastern France in the time of Napoleon I. gained a rapid popularity. Their success was continued in a series of which the best known are: 'Le Fou Yégof (1862); 'L'Ami Fritz' (1864); 'Histoire d'un Conscrit de 1813' (1864); 'Waterloo' (1865); 'Le Blocus' (1867); 'Histoire d'un Paysan' (1868); and 'Contes Populaires.' They also published three plays — 'Le Juif Polonais' (known in its English adaptation as 'The Bells'), a dramatized version of 'L'Ami Fritz' and 'Les Rantzau.' When the two friends met they elaborated the scheme of a work; then Erckmann wrote it. Chatrian corrected it, and sometimes put it in the fire. Erckmann would even be required by his friend to write his story over three times. Latterly the two friends disagreed, and the world received no more of their minute transcripts from the daily life of the Alsatian peasant.

Erdmann, Johann Eduard, yō'hän ĕd'oo-ärd ĕrd'män, German philosopher: b. Wolmar, in Livonia, 13 June 1805; d. Halle 12 June 1892. In 1829 he became a clergyman in his native town, and in 1836 professor extraordinary of philosophy at the University of Halle, being appointed ordinary professor in 1839. He wrote numerous philosophical works, characterized for the most part by their Hegelian tendencies. Of these some of the chief are: 'Body and Soul'; 'Nature and Creation'; 'Outlines of Psychology'; 'Outlines of Logic and Metaphysics'; 'Psychological Letters'; 'Belief and Knowledge,' etc. His greatest work, however, is his 'Outlines of the History of Philosophy,' of which an English translation appeared in 1889.

Erdmann, Otto Linné, ŏt'tō lin-nā', German chemist: b. Dresden 11 April 1804; d. Leipsic 9 Oct. 1869. His researches embrace a wide range of subjects. He examined minutely the technology of nickel, and described some of its compounds; analyzed a number of minerals and slags, and experimented on several other points of inorganic chemistry. In organic chemistry his chief research is upon indigo, in the course of which he discovered isatin. The most important work in which he engaged was that upon the combining weights of several of the elements. In company with Marchand he made determinations of oxygen, carbon, hydrogen, sulphur, calcium, copper, mercury, and some others, and his numbers have been fully confirmed by subsequent experimenters. He was the author of a chemical text-book and for many years conducted the 'Journal für technische und ökonomische Chemie,' which was afterward changed to the 'Journal für praktische Chemie.'

Erdmannsdörfer, ĕrd'mänz-dėrf-ĕr, **Bernhard,** German historian: b. Altenburg 24 Jan. 1833; d. 1901. He held professorships of history at several German universities, and among his more important works are: 'Das Zeitalter der Novelle in Hellas' (1870); 'Deutsche Geschichte vom Westfälischen Frieden bis zur Regierungszeit Friedrichs des Grossen' (1890–4).

Erdmannsdörfer, Max, German musician: b. Nuremberg 1848. He conducted the court orchestra at Sondershausen 1871-80, becoming director of the Imperial Musical Society at Moscow 1882 and professor in the conservatory in that city. He was leader of the Philharmonic Society at Bremen 1889–95, and became leader of the court orchestra at Munich 1896. His chief works are: 'Prinzessin Ilse' (1870); 'Schneewittchen' (1873); and 'Traumkönig and sein Lieb.'

Er'ebus, in Greek mythology, the son of Chaos and Darkness. He married his sister, Night, and was the father of the Light and Day. The Moirai, or Fates, by some are called his daughters. He was transformed into a river, and plunged into Tartarus, because he aided the Titans. From him the name Erebus was given to the infernal regions, particularly that part of it designated as the abode of virtuous shades, whence they pass over immediately to the Elysian fields.

Erebus, Mount, an active volcano on Victoria Land, in lat. 78° 10' S., rising 12,367 feet above the sea. It was discovered in 1841 by Ross, who named it after one of his vessels. His progress further south was barred by a wall of ice.

Erechtheum, ē-rek-thē'ŭm, the temple of Erechtheus (q.v.) on the Acropolis at Athens. It was built in honor of Athene, Poseidon, and Zeus. The name of Erechtheus is associated, as a local hero or demigod, with that of Athene. In this temple was preserved the oldest existing statue of Athene, which was fabled to have fallen from heaven, and the sacred olive-tree created by Athene as a gift to the city, of which she is worshipped as Athene Polias, the protector of the town and state. The building is one of the finest remaining examples of Greek architecture, having been rebuilt during the Peloponnesian war in pure Ionic style. Its ground plan is unusual, resulting from the union under one roof of three separate chapels, or halls of worship. The porch of the caryatides is one of its distinguishing features. In this porch the place of columns is taken by colossal figures of women whose heads support the capitals on which the entablature rests.

Erechtheus, ē-rĕk'thūs, Attic hero or demigod, worshipped in the earliest period of Athenian history. He was brought up by Athene, who placed him while yet a babe in a chest, which was entrusted to Agraulos, Pandrosos, and Herse, the daughters of Cecrops, with the strict charge that it was not to be opened. Unable to restrain their curiosity, they opened the chest, and discovering a child entwined with serpents, were punished with frenzy, and threw themselves down the most precipitous part of the Acropolis. Afterward Erechtheus was the chief means of establishing the worship of Athene in Attica, where he instituted the Panathenæa in her honor. See ERECHTHEUM.

Eremacausis, ĕr'ē-ma-kâ'rĭs, slow combustion (from Greek *ērēma,* gently, and *kausis,* burning), a term employed by Liebig to denote the gradual combination of the constituents of a combustible substance with the oxygen of the air.

Eremites (ĕr'e-mīts) **of St. Francis,** and **Eremites of St. Jerome,** two religious orders of the Roman Catholic Church. The order of the Eremites of St. Francis de Paula was founded by Francis, a native of Paula, in Calabria, 1436, and had there its first house. It received the approval of the Holy See 1474; it is properly styled Order of Minim Hermits of St. Francis de Paula (Ordo Minimorum Eremitarum Sancti Francisci de Paula). Their founder chose the name "Minims" (*minimi,* least, littlest) to keep the brethren ever in mind of the Christian humility to which they were vowed. The order of Eremites of St. Jerome, styled also Hieronymites, consisted originally of hermits, but they adopted the cenobite rule of St. Austin with the approval of Gregory XI., 1373. This order was confined to the Spanish peninsula.

Ere'tria, Greece, an ancient Ionic trading and colonizing town on the southwest coast of Eubœa, which was destroyed by the Persians in 490 B.C., and rebuilt by the Athenians. The recent excavations and explorations made by the American school at Athens and the Greek Archæological Society, have resulted in finding an old temple and many other buildings.

Erfurt, ĕr'foort, Germany, (1) town, in the Prussian province of Saxony, formerly the capital of Thuringia, and a fortress till 1873), situated on the river Gera, about 13 miles west of Weimar. In the 15th and 16th centuries Erfurt was a flourishing commercial and manufacturing place, but its university made it one of the most famous of German cities. The university, established in 1378, was suppressed in 1816. Its trade and manufactures have rapidly increased in recent times along with its population. The most characteristic industry is that of flower-growing, plants and seed being exported in enormous quantities to almost all parts of the world. The most important edifice is the cathedral. The large bell called *Maria gloriosa,* made of the finest bell-metal, and weighing 275 hundredweights, hangs in one of the towers. The cell in which Luther lived while an Augustinian monk, from 1505 to 1512, containing his Bible, portrait, etc., was in the Martinsstift or orphan-house into which the old Augustinian convent had been converted, but was destroyed by fire, along with the relics of Luther, in 1872. According to tradition Erfurt was founded as early as the 5th century, by a certain Erpes. It was not a free imperial city, but always maintained a sort of independence. Saint Boniface established here an episcopal see. In 1483 it concluded a treaty with Saxony, by which it agreed to pay an annual sum for protection. In the 17th century the Elector of Mainz obtained possession of it. The Congress of Erfurt (September–October 1808) was attended by Napoleon, Alexander of Russia, and many German sovereigns. In 1813 the town was taken by the Prussians, after a severe bombardment. In 1814 it was granted to Prussia by the Congress of Vienna. Pop. 73,581. (2) The government of Erfurt of which it is the capital has an area of 1,263 square miles. Pop. 434,180.

Erg (Gr. «work»), in physics, the unit of work in the C. G. S. system. It is the work done in overcoming a force of one dyne, through a distance of one centimetre. See UNITS.

Er'gograph, The, a machine for testing a child's capacity for study, and which shows the degree of fatigue that is experienced by pupils. Its operation is based on the fact that the fatigue of a set of muscles, if accurately measured, will show the extent of the general weariness. The physical deterioration of many school children has been a source of anxiety to both physicians and instructors; if by means of this instrument the exact power of endurance of each pupil can be demonstrated, the course of study can be so arranged as to suit different temperaments and so lessen the mental strain. Also a machine for registering the exact effort made in any feat of strength, testing the comparative and relative strength of various sets of muscles.

Ergot, ėr'gŏt, according to the United States Pharmacopœia, «is the sclerotium of the fungus *Claviceps purpurea* replacing the seed of the rye.» Thus the Pharmacopœia calls for a certain definite kind of ergot for medicinal use; but there are a number of allied species of parasitic fungi that infest not only the rye, but a number of other grasses; other species of the same genus (*Claviceps*), and other genera. Both the botanical and physiological relationships of these forms are close. The ordinary ergot of commerce consists of purplish grain-like masses, one half to three quarters of an inch long and one eighth to one quarter of an inch wide, and somewhat resembling large grains of rye. Microscopically the ergot is made up of the closely matted mycelium of the fungus, which has entirely replaced the cells of the seed.

The fungus is propagated by means of minute spores. These are blown about by the wind, or carried about by insects, and lodge upon rye or other grasses. They there germinate and form a more or less viscid yellowish mass filled with spores of another type, the conidia. These in turn may be carried by insects to other grasses. As the fungus grows and, little by little, replaces the tissue in the grain, there results a brownish to blackish mass which in different species assumes different shapes. These are collected with the different grasses and may be the cause of various types of poisoning in cattle. The fungus growing on rye constitutes the ergot of commerce, which has been used in medicine for many years. The principal sources of ergot at the present time are Spain and Russia.

Chemically considered, ergot is an extremely complex body, and it cannot be said that even at the present time a full knowledge of its composition has been gained. It contains large quantities of an inert fixed oil, a resin, and one or two active principles which, from the earliest chemical investigation to the present, have been called by no less than 50 or 60 different names, among these being ergotine, ecboline, ergotin, cornutine, sphacelic acid, ergotic acid, etc. The unsatisfactory condition of organic drug analysis accounts for these varying results and confusions. The investigations of Kobert (1890) and his students are the first of real merit, and Kobert isolated a body cornutine to which he ascribed the chief activity of ergot. More recently, however, Jacobi, a student of Schmiedeberg, has isolated two bodies, sphacelotoxin and chrystoxin which are, he claims, the active principles.

Taken internally, ergot has the singular power of stimulating an involuntary muscle, causing it to contract. In this manner it produces a number of reactions on those organs which are rich in this type of muscular fibre. Acting on the heart and blood vessels, it contracts the cardiac muscle and the arterial walls, causing an increase in the force of the heart's contraction and a marked rise in the blood-pressure. It also stimulates the unstriped muscular tissue of the stomach and intestines, occasionally causing purging with violent peristalsis. The organ in the body containing the greatest amount of unstriped muscular tissue is the uterus, and naturally the action of ergot would be most forcibly manifested in this organ. It here causes contractions, the uterus becoming hard and pale, and forces the blood out of the uterine blood vessels. During pregnancy the action is much more pronounced, since the uterus is so much more dilated. Ergot has many applications in medicine, but its chief uses are to control blood pressure and to treat uterine disorders.

Er'gotism. In the article on ergot it has been shown that there are a great many closely related parasitic fungi, growing on different varieties of grasses. A number of these infected grasses, belonging to the ergot family produce, when eaten by cattle, forms of acute and chronic poisoning. These are characterized by changes, particularly in the blood vessels, causing swellings below the knees or ankles, with gangrene of the skin, and at times symptoms of paralysis of the extremities. In years in which unusual humid conditions have permitted the wide and abundant growth of these parasitic fungi, large areas of pasture land have become infected, resulting in widespread poisoning of cattle, almost resembling epidemics.

In Europe, where the eating of rye bread is much more common than in this country, particularly in Russia and Italy, cases of chronic poisoning by ergot occur in man from eating the bread made from infected grain. The chief symptoms here are those referable to changes in the blood vessels of different parts of the body, with secondary consequences. Thus, in some, there is a loss of touch-sensations in the hands and feet, a condition which may go on to the formation of ulcers and gangrene. This is the result of the cutting off of the blood supply to the periphery of the body by the contracting influence of the poison on the walls of the blood vessels. In some cases disease of the spinal cord results. This is thought to be due to the artificially induced anæmia with secondary degenerations in the columns of the cord. This disease, called pellagra, closely resembles a toxic neuritis, or locomotor ataxia. See ERGOT; PELLAGRA.

Eric, ē'rĭk or ā'rĭk, the name of several Danish and Swedish kings. ERIC VII., king of Denmark, b. 1382; d. Rügenwald 1459; the son of Duke Wratislaw of Pomerania, was selected as her successor by Queen Margaret of Denmark, and in 1412 mounted the throne of Denmark, Norway, and Sweden, united by the treaty of Calmar. Cruel and cowardly in character, he lost Sweden in 1437 through a revolt of the peasants of Dalecarlia, and in 1439 was deposed also in Denmark. ERIC VIII., "THE SAINT," became king of Sweden in 1155, did much to extend Christianity in his dominions, and to improve the laws, and fell in battle with the Danes in 1160. ERIC XIV., the last of the name who reigned in Sweden, succeeded in 1560 to the throne of his father, the great Gustavus Vasa, and at once began to exhibit the folly that disgraced his reign. He married a Swedish peasant girl, who acquired an influence over him which was ascribed by the superstitious to witchcraft; she alone was able to control him in the violent paroxysms of blind fury to which he was subject. His capricious cruelties and the disastrous wars that followed on his follies at length alienated his subjects, who threw off their allegiance in 1568 and elected his brother John to the throne. In 1577 he ended his miserable life half voluntarily by a cup of poison. He had a genuine love of letters, and solaced his captivity with music and the composition of psalms. His story has been worked into dramatic form by Swedish poets; in German by Kruse in his tragedy, 'King Erich' (1871).

Eric the Red, the colonizer of Greenland: b. Norway about 950. After committing homicide he fled to Iceland and in 984, again seeking asylum as a murderer, he reached Greenland. Here he built a chief town, called Gardar, which he settled with Norwegians. His son, Leif Ericson, introduced Christianity, but after flourishing for about four centuries the colony was wiped out, probably by some such plague as black death, although recent authorities attribute its disappearance to famine.

Ericaceæ, ĕr-ĭ-kā'sē-ē, the heaths, a family of shrubs or under-shrubs with small leaves, evergreen in some of the genera, rigid, whorled, or opposite, and without stipules. The flowers are arranged in various styles of inflorescence, and are generally very beautiful, the heath probably excelling all other families in the universal beauty of its blossoms. Different writers number the genera from 40 to 70, and the species from 1,000 to upward of 1,300. They are of very wide distribution, the greater number being natives of South Africa. In the North American flora, at least 20 genera are represented, among them such plants as the azaleas, rhododendrons, kalmias, trailing arbutus, and the heaths.

Er'ichsen, SIR **John Eric,** English surgeon: b. Copenhagen, Denmark, 19 July 1818; d. Folkestone, England, 23 Sept. 1896. He became a member of the Royal College of Surgeons in 1839, and in 1850 professor of surgery at University College. In 1865 he succeeded Quain as professor of clinical surgery in the same college, a post which he held till his retirement in 1875. He was appointed president of University College in 1887, and held that post till his death. His most important work was his 'Science and Art of Surgery' (1853), which has gone through many editions, and has been translated into several languages. He also published a volume on 'Concussion of the Spine' (1875).

Ericht, ĕr'ɪʜt, **Loch,** a lake in the Grampian Mountains, in Scotland, on the boundary between the counties of Perth and Inverness; it is 60 miles northwest of Perth. It is 14⅝ miles long, from ¼ to 1⅛ miles wide, and 1,153 feet above sea-level. It has two outlets, one flows into Loch Lydoch and one into Loch Rannoch.

Erichthonius, in Greek mythology, the son of Dardanus and Bateia, and grandson of Zeus. He obtained the kingdom of Troy by the death of his brother Ilus without children. He married Astyoche, the daughter of Simos, by whom (or according to some by Callirrhoë, the daughter of Scamander) he became the father of Tros. The myth or tradition of Erichthonius is sometimes blent or confused with that of Erectheus.

Ericson, Leif, līf ĕr'ik-sŏn, Icelandic discoverer. According to Sagas he was the son of Eric the Red (q.v.) and at the beginning of the 11th century discovered a transatlantic country, which he called Vinland, from the vines which abounded there. Here an Icelandic settlement was established, but whether the coast was Labrador, Newfoundland or some region farther south has not been decided. A much idealized statue of Leif Ericson adorns Commonwealth Avenue, Boston, the work of Miss Anne Whitney, the sculptor.

Er'icsson, John, American inventor: b. Wermland, Sweden, 31 July 1803; d. New York 8 March 1889. He entered the Swedish army in 1820, but resigned in 1827, and soon became known as an inventor. In 1828 he made the first application to navigation of the principle of condensing steam and returning the water to the boiler; later he brought out a self-acting gunlock by means of which naval cannon could be automatically discharged at any elevation without regard to the rolling of the ship. In 1833 he designed a caloric engine; and in 1836

JOHN ERICSSON,

INVENTOR OF THE MONITOR.

invented the screw propeller, which revolutionized navigation. Ericsson came to the United States in 1839 and two years later built the screw-propelling warship Princeton for the government. This was the pioneer of modern naval construction and the foundation of the steam marine of the world. The achievement, however, which made him most famous in the United States was the construction in 1861 of the ironclad Monitor, which was built under a patent granted by the United States government to Theodore Ruggles Timby (q.v.), the inventor of the revolving turret, etc., was launched 100 days after its keel was laid, and arrived in Hampton Roads just in time to defeat, on 9 March 1862, the Confederate ironclad Merrimac, which had destroyed several wooden warships. But for this signal victory the result of the War would doubtless have been changed and European interference attempted. A fleet of monitors was soon built and did important service during the remainder of the War. His remains were taken to Sweden on the cruiser Baltimore, and interred with imposing ceremonies. The centenary of his birth, 31 July 1903, was observed in New York by the unveiling of a bronze statue of the inventor in Battery Park and in Worcester, Mass., which has a Swedish population of 2,000, by public orations and eulogies.

Ericsson, Nils, Swedish engineer: b. Stockholm 31 Jan. 1802; d. there 8 Sept. 1870. He was a brother of John Ericsson (q.v.). He received the appointment as colonel of the Naval Engineering Corps 1850, becoming director of government railroad construction 1858. Among his engineering achievements were the construction of the Stockholm docks, the canal between Lake Saima and the Gulf of Finland and the Trollhättan Canal sluices.

Eridanus, ē-rĭd'a-nŭs, a river famous in mythology, mentioned in the return of the Argonauts. It is located in northern Europe and by some said to mean the Rhône, but generally thought to refer to the Po, in Italy. When Phæthon was struck by the thunderbolts of Zeus he fell into this river — and his three sisters, the Heliades, lamented him until they were changed into poplars. They did not cease to weep for him even in this condition; and their tears falling into the water of the river, became transparent amber.

Erie, Kan., city, county-seat of Neosho County; 115 miles west by south of Wichita; on the Atchison, T. & S. F. and the M. K. & T. R.R.'s. It is surrounded by a good farming country; and contains flour-mills, grain elevators, and lumber yards. There are oil and natural gas fields nearby. Pop. 1,318.

Erie, Pa., city, port of entry, county-seat of Erie County, on Lake Erie, and on the Lake Shore, the Pennsylvania, the Erie, and several other railroads; 85 miles southwest of Buffalo; 100 miles northeast of Cleveland. Erie is on a bluff having a grand view of the lake, is laid out with broad streets at right angles with each other, and has several large and attractive parks. It is lighted with gas and electricity, and has a bountiful supply of water from the lake. The peculiarly advantageous location of Erie has given it high rank as a shipping and manufacturing point. It has the largest land-locked harbor on Lake Erie. The harbor has been greatly improved, and is now 5 miles long by 1 mile wide, depth 9 to 25 feet. Presque Isle, lying directly in front of the city, furnishes means of ample protection; three lighthouses stand at the entrance to the harbor, and substantial wharves, where merchandise is transferred directly from vessels to cars, extend along the entire front. The principal industries are manufactures of iron, steam engines, machinery, car-wheels, car-work, and stoves; flour and grist mill products, brick, leather, organ, pump, furniture, and various kinds of woodwork factories, petroleum refineries, breweries, and malt-houses. The leading articles of shipment are lumber, bituminous and semi-bituminous coal, iron ore, petroleum, and manufacturing products, and these are conveyed by railroads, steamboats, and sailing vessels that ply regularly between Erie and other ports on the Great Lakes. Among the notable buildings are the City Hall, Union Depot, Government Building (including Post-office, Custom House, and other departments), State Soldiers' and Sailors' Home on Garrison Hill, Hamot Hospital, St. Vincent Hospital, Protestant Home for the Friendless, United States Marine Hospital, and Central School. Near the city is a memorial in the form of a blockhouse, erected by the State, in honor of Anthony Wayne. The city has excellent public and private schools, a public library, daily and weekly newspapers, three national and several savings banks. Erie occupies the site of a French fort, called Fort de la Presque, built in 1749; was laid out as a town in 1795; had a portion incorporated as a borough in 1805; and the whole was given a city charter in 1851. It was the headquarters of Commodore Perry in the War of 1812; the fleet with which he defeated the British in the battle of Put-in-Bay (10 Sept. 1813) was built and equipped here. Natural gas was discovered in 1889. Pop. (1900) 52,733.

Erie Canal. See CANALS.

Erie, Fort. See FORT ERIE.

Erie, Lake, one of the Great Lakes of North America; situated between lat. 41° 30′ and 42° 52′ N., and lon. 78° 53′ and 83° 25′ W. It lies between Lakes Huron and Ontario and is bordered on the north by Canada, on the east and south by New York, Pennsylvania, and Ohio, on the west by Ohio and Michigan. Its greatest extent is northeast and southwest; it is about 245 miles long, 50 miles wide (from 28 to 58), and has an area of about 9,900 square miles; is 573 feet above sea-level, 8 feet below Lake Huron; has a maximum of 210 feet, and an average depth of 100 feet. It receives, through the strait, Detroit River, the waters from all the other Great Lakes except Ontario; and the chief streams exclusive of the waters from the Great Lakes which flow into it are the Grand, from the north, the Maumee, Sandusky, Huron, Grand, and Cuyahoga from the south. Its outlet is Niagara River which flows into Lake Ontario. Some of the indentations are the bays of Sandusky and Maumee, on the south coast, and Long Point Bay on the north. In the western part is a group of islands, some of which are Point Pelee, Kelly's, North, Middle, and South Bass. Lake Erie is the shallowest of all the Great Lakes, and dangers to navigation are increased by the heavy ground-swell. In 1670 the Weather Bureau of the United States established a number of stations on the Great

Lakes, and since have made accurate observations and reports on the rainfall, the changes taking place, and other matters connected with these lakes. In 1872 the water in Lake Erie was below normal, and the rainfall was below normal at every station on the Great Lakes (Ontario stations not considered in these statements). In 1876 the water in Lake Erie was higher than usual, the rainfall at all stations above normal except Marquette, where it was nearly an inch below. In 1878 the Lake was again high; the rainfall also above normal except at Duluth and Grand Haven, where it was below normal. In 1882 the Lake was again above normal, and at 10 stations the rainfall was above normal, but at Milwaukee, Detroit, and Buffalo it was below normal. In 1902 the rainfall at all stations was heavy and Lake Erie was above normal. The effect rainfall has on the level of Lake Erie has been shown from the observations made since 1870. The destruction of lakes is largely due to filling from deposits brought by inlets or tributaries; every particle of sediment brought into a lake tends toward its destruction. Another danger is in changes in outlets. Where the Niagara River emerges from Lake Erie there has been but little change for centuries. It flows through a plain, and the channel is to-day, apparently, what it was hundreds of years ago; but «Niagara is wearing back its falls toward Lake Erie; and in given time, as a result of this work, it will so lower the outlet as to completely drain Lake Erie.» The importance of Lake Erie for commercial purpose has been greatly enhanced by its canal connections. The Welland Canal around Niagara Falls removes obstacles to direct navigation from the Atlantic; the Erie Canal connects the Lake by a short route, with the Hudson River; canals crossing Ohio connect the Lake with the Ohio River. There are many excellent harbors, not all of them in use by the large steamship lines. Some of the principal ports are Buffalo, Erie, Cleveland, Sandusky, and Toledo. At Put-in-Bay, near Sandusky on 10 Sept. 1813, took place the Battle of Lake Erie (q.v.) The Americans were successful, and the result was most important to the United States; it had much to do with the regaining of the territory of Michigan, which at the time was in possession of the British. Consult: Russell, ‹Lakes of North America›; Smithsonian An. Report, ‹Modification of Great Lakes by Earth Movement› (1898).

Erie, Lake, Battle of, 10 Sept. 1813: a naval battle which annihilated the British fleet on that lake, and gave the Americans their northwest at the Treaty of Ghent. In 1813 it had become evident that the reconquest of the northwest from the British, who had captured Detroit and were building a fleet at Malden, near by to control the Lake, depended on wresting the control from them; and Oliver Hazard Perry spent from 27 March till September building a rival fleet at Presque Isle, now Erie, Pa. It had nine vessels: the Lawrence, flagship, 20 guns; the Niagara, Capt. J. D. Elliott, 20 guns; the Caledonia, three-gun brig; five two-gun schooners and a one-gun sloop; in all 54 guns with 714 pounds metal at a broadside. The British had six vessels averaging much heavier, with 63 guns averaging much lighter — about 430 pounds to a broadside; but most of them were far longer range than the American, whose policy therefore was close action. The crews were about equal, some 500 each. The British commandant was Capt. Robert H. Barclay, a veteran of Nelson's; two of the captains were veterans also. The fleets engaged off the islands north of Sandusky Bay, near noon of 10 September. Perry in the Lawrence, with two gunboats, came to close quarters shortly after, and if the whole fleet had followed, the British would soon have been overwhelmed; but for some reason (hotly disputed and a sore point for many years) the other vessels kept off and played away at long range, while for two hours the British vessels concentrated their fire on the Lawrence. Such carnage was scarcely ever known on the ocean; of 103 officers and men, but 20 were unhurt; the vessel was literally shot to pieces, and the very wounded were killed on the surgeon's board by the crashing balls. Seeing that no more could be done with it, Perry turned over the command to a lieutenant, transferred himself in a small boat to the Niagara, now tardily drawn nearer, brought that and the rest into close action, and in 15 minutes (about 3 P.M.) forced the entire British fleet to surrender. The latter was in a dreadful condition, too; the English had fought with heroism and skill, but a third of its force was disabled or dead. The losses were: Americans, 27 killed, and 96 wounded; British, 41 killed and 94 wounded. The battle raised Perry to the summit of naval fame, justly, for no victory was ever more due to the genius and energy of one man, and few naval battles have had such momentous results. The remains of the slain officers were buried at Put-in-Bay Island in 1858. Maclay's ‹History of the Navy› (Vol II. 1894); Spears' ‹History of Our Navy› (1899); Roosevelt's ‹History of the Naval War of 1812› (1882); Henry Adams, ‹History of the United States› (Vol. VII. 1891).

Erie Railroad. Chartered 24 April 1832, by the New York State Legislature to construct a railroad from Lake Erie to the Hudson river, the New York & Lake Erie Railway Company was organized with a capital of $3,000,000, the credit of the State being extended to a like amount. The charter provided that the road should make no connection with any railroad in New Jersey or Pennsylvania without special legislative consent and also provided that it should run through the southern tier counties of New York. This plan was in accordance with the idea advanced by W. C. Redfield in 1830 when he proposed a railroad from the Atlantic to the Mississippi river. His plan was that it should be a great national road to follow the so-called «Appian Way» advocated by Generals Clinton and Sullivan in 1780 to further the development of what then constituted the United States.

In 1841, the railroad was opened from Piermont, at the extreme southern point of New York State on the Hudson river, inland to Goshen, Orange County, a distance of 46 miles. Opposed at it was by the canal counties and their representatives in both the State and National Legislatures, the Erie had to fight for its existence from its birth through a series of legislative obstructions and financial manipulations that developed even in its early days. Before its completion to Dunkirk, which was the objective point on Lake Erie, and as a consequence of these obstacles to progress, the road had to be placed in the hands of a receiver. In 1845, the State released its claim for the money advanced for construction and through the energetic efforts of the Erie's friends, it was finally opened by President Fillmore, Daniel Webster, his Secretary of State, and other government and state officials, from Piermont to Dunkirk, on 22 April 1851, a distance of 463 miles. From Piermont, passengers were conveyed to New York by steamer. This operated so much to the disadvantage of the road that its charter was amended in 1852 permitting it to pass through New Jersey to its present terminal in Jersey City, and Piermont was abandoned as a terminal in May, 1861. Previous to that abandonment, the road was again — in 1859 — in the hands of a receiver and was sold to the Erie Railway Company in 1861. This new company also bought the Buffalo and New York City Railroad and so secured independent entrance into Buffalo, which was made its principal lake terminal in place of Dunkirk. It has so remained up to this time. The company also took over the Union Steamboat Company, operating on Lake Erie, in the same year and so added Cleveland and Detroit to its lake terminals.

In accordance with English ideas, the road was built with a six foot gauge, a mistake in construction that for years acted as a deterrent to its successful operation, owing to the fact that contents of cars had to be transferred at connecting points. Another mistake of its early managers was a refusal of the Erie to accept entrance into New York City over the New York & Harlem lines, then being constructed and which later passed to the control of the New York Central. But this management did see the value of the coal traffic and in 1861, it entered the anthracite coal fields of Pennsylvania and later through its Bradford branch, reached the bituminous fields. But in the meantime, it had become a financial foot-ball in Wall street, partly through a desire to combine with the Atlantic & Great Western, then building through Ohio, for the purpose of making a route to St. Louis on the Mississippi river. A connection to the Ohio river at Cincinnati was ultimately effected through a combination with the Atlantic & Great Western and an operating connection with the C., H. & D. completed 33 years after the first work on the Erie was begun.

In 1867, Jay Gould and Colonel James Fisk came into possession of the Erie and from 1868 to 1872 a fight ensued between Gould, Vanderbilt, Fisk, James McHenry, and Daniel Drew for the possession of the property, resulting in its spectacular wreckage after one of the bitterest and most vindictive railway wars in history. The contest for the possession of the property and the financial manipulations indulged in enriched all who were interested excepting the actual owners of the road and these it impoverished as it did the road itself. At the conclusion of this historic fight, Hugh J. Jewett came in as president in 1874 and a year later was made receiver, the property having been purchased by the security holders to prevent its complete wreckage. It was reorganized in 1878 as the New York, Lake Erie & Western. It then owned 525 miles of road and leased 400 more. The road was converted into a standard gauge road at a cost of $25,000,000 and was double tracked from Jersey City to Buffalo.

Attempts to enter Chicago, first over what is now known as the "Panhandle Route," and later over the Pittsburg, Fort Wayne & Chicago were successfully blocked by rivals and it was not until 1883 that it secured an entrance into the western metropolis over the Chicago & Atlantic Railway. Under succeeding managements, the road, in spite of the enormous financial obligations which hampered it, was operated as a paying and successful property until the panic of 1883–4. The obligations accruing because of its purchase of the Chicago & Atlantic and Pennsylvania coal properties led the road to still further embarrassment and finally to another receivership in 1893. Two years later, the company was reorganized as the Erie Railroad Company and assumed possession of the property on 1 Dec. 1895, which it has since operated.

The history of the Erie Railroad is briefly the history of railroading in the United States. The total mileage of the Erie is 2,147, made up as follows: *Erie Division*: New York Div., 197 miles; Delaware Div., 128 miles; Susquehanna Div., 140 miles; Jefferson Div., 43 miles; Tioga Div., 65 miles; Rochester Div., 146 miles; Buffalo Div., 203 miles; Alleghany Div., 131 miles; Bradford Div., 83 miles; Wyoming Div., 59 miles. *Ohio Division*: Meadville Div., 225 miles; Cincinnati Div., 197 miles; Mahoning Div., 164 miles; Lima Div., 127 miles; Chicago Div., 123 miles; Greenwood Lake Div., 52 miles; Northern R. R. of New Jersey, 26 miles; New Jersey & N. Y. R. R., 38 miles.

For the year ending 30 June 1905, the total earnings were $45,724,737, other income $1,048,689, operating expenses $33,142,208, leaving a total net income of $13,631,218.

A pioneer as a trunk line, it was also the first railroad to adopt what are now universal methods — among these, the running of trains by telegraph, the use of a printed time table, the running of Sunday trains, emigrant trains, and special service for suburban passengers, the use of parlor cars, the establishment of dining rooms along the line, the establishment of special milk trains, the running of a newspaper special train (this being done in 1842). It was also the first road to run an excursion train of the modern type with a brass band and a reduced round trip fare, the first road to use a bell cord to signal from the conductor to the engineer, the first to build up local industries by furnishing to manufacturing companies the use of switching and terminal tracks, a custom now so universal, and in more modern days, the first road to adopt all-steel baggage, express, and mail cars.

J. H. Maddy,
Special Representative.

Erigena, ĕ-rĭj'ĕ-na, **Johannes.** See Scotus, Johannes Erigena.

E'rin, an old name for Ireland. Now used only in poetry.

Erinite, a basic copper arsenate having the formula $Cu_5(OH)_4As_2O_8$, occurring as a dark green crystalline coating of fibrous structure in Cornwall, England, and the Tintic district, Utah. The name is also applied to an aluminum silicate from the Giant's Causeway, Ireland.

Erinna, ē-rĭn'a, Greek poetess: b. Rhodes or Teos, about 600 B.C.; d. at age of 19. According to some she was a Lesbian, and the intimate friend of Sappho. Others aver that she was born at Teos, Rhodes, or Telos, and that she lived in the age of Demosthenes; while others again assert that there were two poetesses of the same name. She left behind her a few poems which were thought equal to those of Homer in point of merit. The chief of them was a work of about 300 lines, called 'Elakatē' (The Distaff), of which nothing has come down to us.

Erinyes, ĕ-rĭn'ĭ-ēz. The Furies (q.v.).

Eriocaulon, ĕr-ĭ-ō-kâ'lòn, the typical genus of the pipewort family (*Eriocaulonaceæ*). See Pipewort.

Eriodendron, ĕr-ĭ-ō-dĕn'dròn, a genus of tropical trees of the natural order *Malvaceæ*. There are about a dozen species, which are characterized by digitate leaves, medium to large, white or reddish, solitary or clustered flowers, and thick, woody seed-capsules containing a cotton-like fibre which suggested the name silk cotton-tree. Some of the species exceed 100 feet in height, and furnish wood used in making boats. The seeds of several species are used for food to some extent. But the principal economic value for which these trees are noted is in the fibre which surrounds the seeds. This is too short to be successfully woven like cotton, but is highly valued in upholstery for stuffing cushions, lounges, etc., for making floss and, it is said, as a substitute for animal hair in making felt for hats. The chief source of supply is Java. It is known in various countries as kapok, rimi, bentang, etc. Various South American species of *Bombax,* a related genus, also furnish a similar fibre. Like many other species of the natural order *Malvaceæ*, the species of these two genera also furnish a valuable bast fibre which is used for rope and cordage-making. One species, *E. occidentale,* is grown in California to a small extent as an ornamental tree under the name *Ceiba occidentalis.*

Eriom'eter, an optical instrument for measuring the diameters of minute particles and fibres from the size of the colored rings produced by the diffraction of the light in which the objects are viewed.

Eriphyle, ĕr-ĭ-fī'lē, in the Greek mythology, the daughter of Talaus, and wife of Amphiaraus, whom she betrayed for a necklace presented to her by Polynices. The necklace was made by Hephæstus (Vulcan), and had the power of rendering whoever wore it unlucky.

Eris, ē'rĭs or ĕr'ĭs, in Greek mythology the goddess of discord, daughter of Night, and sister of Nemesis, and the Parcæ or Fates. Not being invited to the marriage of Peleus, she revenged herself by means of the apple of discord. See Paris.

Er'ith, England, town in Kent, on the Thames, about 14 miles east of London, contains the Maxim-Nordenfeldt gun-factory, engineering works, and other manufactories. Several yacht clubs have their headquarters here. Pop. 25,862.

Eritrea, ā-rē-trā'a, or **Eryth'ræa** (from Greek *erythros,* red, referring to the Red Sea), the official name of an Italian colonial possession stretching along the African shore of the Red Sea from Cape Kasar in lat. 18° 2' N. to the Sultanate of Raheita on Bab-el-Mandeb in lat. 12° 30' N. The coast-line is between 500 and 600 miles in length, and the area of the colony is about 94,800 square miles. The chief town is Massowah. Pop. of the colony about 400,000, the majority of whom are Arabs.

Erivan, ĕr-ĭ-vän', Russia, (1) a fortified town, capital of the government of the same name in Transcaucasia; on the Sanga River, 33 miles northeast from Mount Ararat. The manufactures consist of cottons, earthenware, and leather; and the situation of the town, on the caravan route between Russia and Persia, gives it a considerable transit trade. Pop. 30,275. (2) The government of Erivan has an area of 10,745 square miles, and a pop. of 1,128,003.

Erlangen, ĕr'läng ĕn, Bavaria, town on the Regnitz, 12 miles north of Nuremberg. As old as the 10th century, it owes its prosperity to the settlement here of French Huguenots after the revocation of the Edict of Nantes (1685), and to its university. The chief manufactures are articles made from wood, ivory, and horn, and some cotton goods. It has large breweries. Pop. 23,113.

Erlangen, University of, a Lutheran institution founded in 1742 in Baireuth, but the following year moved to Erlangen (q.v.). In 1760 Alexander, the then margrave of Baireuth, gave valuable assistance to the university and the name was changed to its present legal title, «Friedrich-Alexander University.» Owing to the changes of government of the country the growth of the institution was retarded until 1880. Since that time the school has increased in attendance and influence. In 1903 the number of pupils enrolled was about 1,200. Consult: Minerva.

Erlau, ĕr'low, or **Eger,** ā'ger, Hungary, town, capital of the county Heves, on the Eger, 75 miles east-northeast of Budapest. The manufactures consist chiefly of woolen and linen cloth, hats, combs, leather, shoes, and harness. The finest red wines of Hungary are made from grapes grown in the neighborhood. There are two thermal springs, one on each side of the river. Pop. 25,102.

Erl'king (Ger. *Erlkönig*), a mythical personage first introduced into German poetry, through Herder's translation of a Danish ballad, 'The Erlking's Daughter,' and made familiar to all readers by Goethe's ballad, 'Der Erlkönig,' or translations of it. This goblin is represented as exercising a malignant and fatal influence upon men, and especially children, by alluring promises or visions which lead to their destruction. The word is of Danish origin (*Ellerkonge,* or *Elverkonge,* king of the elves).

Erman, ĕr'män, **Adolf,** German Egyptologist: b. Berlin 31 Oct. 1854. He was educated at Leipsic and Berlin, receiving an appointment as associate professor of Egyptology in the University of Berlin 1883, becoming director of the Egyptian department of the Royal Museum 1855 and attaining full professorship in the university in 1892. He has paid special attention to Egyptian grammar and has written many works on Egyptology, among which are: 'Die Pluralbildung des Ägyptischen' (1878); 'Neuägyptische Grammatik' (1880); 'Die Sprache des Papyrus Westcar' (1889); 'Die Märchen des Papyrus Westcar' (1890); 'Altägyptische Grammatik' (1894); 'Gespräche eines Lebensmüden mit seiner Seele' (1896); 'Die Flexion des Ägyptischen Verbums' (1900); 'Zaubersprüche fur Mutter Kind' (1901); 'Ägypten und Ägyptisches Leben im Altertum' (1885), translated into English by Tirard with title of 'Life in Ancient Egypt' (1894).

Ermine, ėr'mĭn, any weasel (q.v.) which turns white in winter, as is the habit of all those living in snowy regions; or its pelt made up as a fur. The animal's coat becomes completely yellowish white, except the tip of the tail, which remains black. When this fur is made up into tippets, coat trimmings or garments, the black tails are attached as ornaments in rows, which gives the regularly spotted effect characteristic of ermine furs, and imitated in heraldry, under the terms "ermine" and "erminois," expressive of furs as a bearing. In mediæval times the use of this kind of fur was restricted to royalty, and later it became a part of the insignia of judges in high courts, perhaps as a symbol of the majesty of the law; whence the expression "the ermine" as a metonym for the judiciary office. Ermine is mainly derived from northern Russia and Siberia, where it is the fur of the stoat (*Putorius erminea*); but a great amount is supplied by northern Canada, from two or three American species of weasels.

Ermine Moth, any of several white moths marked with black spots as in ermine furs. The name is given in America to various bombycids, but was originally applied to a European zygænid (*Ypomoneuta pellida*).

Ermine or **Ermyne Street,** one of the four great roads constructed in England by the Romans. It led from Bishopsgate, London, by way of Durolipons (Godmanchester), Lindum (Lincoln), Danim (Doncaster) to Eburacum (York), whence it continued northward past Hadrian's wall into Scotland. At Lincoln it formed a junction with the Foss Way, leading to the southwest. The Vicinal Way, a branch from London, led through Essex, Suffolk, and Norfolk to Venta Icenorum (Caistor near Norwich) and connected with the main road at Durolipons by a branch from Camulo-dunum (Colchester).

Ern, or **Erne,** a name in poetic rather than common or scientific use for any of the sea-eagles; specifically the European white-tailed eagle of which the American bald-eagle (*Haliæctus leucocephalus*) is a near relative. See EAGLE.

Ernest Maltravers, a novel by Bulwer-Lytton, published 1837. Its sequel is entitled, 'Alice; or The Mysteries' (1838). In the preface to the first-named novel, the author states that he is indebted for the leading idea of the work — that of a moral education or apprenticeship — to Goethe's 'Wilhelm Meister.' The apprenticeship of Ernest Maltravers is, however, less to art than to life. 'Ernest Maltravers' is written in the Byronic strain, and is a fair example of the English romantic and sentimental novel of the thirties.

Ernesti, Johann August, yō'hän ow'goost ĕr-nĕs'tē, German scholar: b. Tennstädt, Thuringia, 4 Aug. 1707; d. Leipsic 11 Sept. 1781. He studied at Wittenberg and Leipsic, and, devoting himself to classical studies, became rector of the Thomas School at Leipsic in 1734, a post which he held till 1759. He became professor of theology in the university in 1759. He prepared editions of Homer, Callimachus, Polybius, Suetonius, and Tacitus, and of Xenophon's 'Memorabilia' and Aristophanes' 'Clouds,' and an excellent edition of Cicero (3d ed. 1776–7), to which he added a valuable 'Key to Cicero,' often reëdited. He was the founder of a true exegesis of Scripture by the laws of grammar and history, independent of dogmatic prepossessions. His 'Latin Speeches' gained him the name of the "German Cicero."

Ernouf, ār-noof, **Alfred Auguste,** French historical writer and publicist: b. Paris 21 Sept. 1817; d. there 15 Feb. 1889. 'New Studies of the French Revolution' (1852–4); 'The French in Prussia, 1807–8' (1872); and other works by him evince research and impartiality.

Ernst (ĕrnst) **I.** (surnamed "THE PIOUS"), Duke of Saxe-Gotha: b. castle of Altenburg 24 Dec. 1601; d. 1675. He was the son of John, Duke of Weimar, and brother of the famous Bernard of Saxe-Weimar. He fought with distinction as colonel of horse under Gustavus Adolphus, at the battles of Nuremberg, Lützen, and Nördlingen during the Thirty Years' War, and was one of the signatories to the Peace of Prague in 1635. He afterward became famous for the wisdom of his administration, for the reforms that he instituted, and for the progress his principality made during his reign. He was the founder of the Gotha line which became extinct by the death of Frederick IV. in 1824. Consult: Beck's 'Ernst der Fromme' (1865).

Ernst II., Duke of Saxe-Gotha and Altenburg: b. 1745; d. 1804. On succeeding his father in the dukedom he set about to reform the government, and ameliorate the condition of his people. He refused to allow his army to join the forces of his near relative George III., in fighting against the American colonies, although large sums were offered as an inducement. He was a patron of science; instituted for the first time a measurement of an arc of the meridian in Germany, and established an observatory near Gotha. He wrote on astronomy, and among his works are: 'Astronomische Tafeln' (1799).

Ernst II., Augustus Charles John Leopold Alexander Edward, Duke of Saxe-Coburg-Gotha: b. Coburg 1818; d. 1893. He was brother of Prince Albert, consort of Queen Victoria of England, and seems to have resembled him in tastes and character. He was instrumental in winning the battle of Eckeonporde in the war against Denmark, fought on the side of Prussia in the Austro-Prussian and Franco-Prussian wars. He wrote some successful operas.

Ernst August, ŏw'goost, King of Hanover and Duke of Cumberland: b. 5 Jan. 1771; d. 18 Nov. 1851. He was the 5th son of George III. of England. He took up his abode at Berlin, but returned to England while the discussions on Catholic emancipation were going on, and endeavored by every means in his power to prevent the passing of that measure. On the death of William IV. in 1837 he ascended the throne of Hanover, in consequence of the succession to the sovereignty of that country being limited to male heirs. His arbitrary and tyrannical disposition, which had hitherto shown itself in opposing every step in the way of political reform and progress, was now manifested by his abrogating the constitution which had been granted in 1833. In 1848, however, he was compelled to accede to popular demands, and accord the nation a more liberal form of government. He was succeeded by his son, George V., the last of the Hanoverian kings. The unpopularity of the Duke of Cumberland in Britain was extreme, and the contingency of his succeeding to the throne was regarded as one of the greatest misfortunes that could befall the nation. See Wilkinson ‘Reminiscences of King Ernest of Hanover’ (1880).

Ernst Ludwig, Grand Duke of Hesse: b. Darmstadt 1868. He succeeded to the throne in 1892.

Ernst, August Frederic, American educator: b. Hanover, Germany, 25 June 1841. He was graduated at the gymnasium, Celle, Hanover, in 1859; studied later at the University of Göttingen, and came to the United States in 1863. He was pastor of Lutheran congregations till 1869, when he became a professor in the Northwestern University. He was chosen president of the university in 1870; and was president of the Joint Lutheran Synod of Wisconsin, Minnesota, and Michigan, in 1892–5–7–9.

Ernst, Harold Clarence, American bacteriologist; b. Cincinnati, Ohio, 31 July 1856. He was graduated at Harvard University in 1876 and at its Medical School in 1880; and became professor of bacteriology there. He has published: ‘Infectiousness of Milk’ (1896); ‘Infection and Immunity’ (1898); ‘Prophylactic Hygiene’; etc., and numerous articles in scientific medical periodicals.

Ernst, Heinrich Wilhelm, hīn'rĭн vil'hĕlm ĕrnst, Austrian composer and violinist: b. Brünn 1814; d. Nice, France, 8 Oct. 1865. He was educated at the Vienna Conservatory and made his début in Munich 1830, and subsequently met with a warm reception in the principal cities of Germany. A like success attended him all over the continent. His principal compositions are his ‘Elegy’, and the ‘Phantasy from Othello.’

Ernst, Henry, American educator: b. Anspach-Uringen, Germany, 17 May 1842. He was educated in Germany and in the United States; was graduated at Concordia Seminary, St. Louis, Mo., and at the Capital University, Columbus, Ohio. He entered the Lutheran ministry in 1865, and remained actively in it till 1885, when he became president and professor of theology in the Lutheran Theological Seminary, St. Paul, Minn.

Ernst, Oswald Herbert, American military officer: b. near Cincinnati, Ohio, 27 June 1842. He was graduated at the United States Military Academy and was commissioned a brigadier-general of volunteers 1898. He was engineer in charge of western river improvements in 1878–86; had charge of harbor improvements in Texas in 1886–9; and while on the latter service began the great work which resulted in the dredging of the channel at the entrance of Galveston harbor from 12 to 26 feet. In 1893–8 he was superintendent of the United States Military Academy. In the war with Spain he went with Gen. Miles to Porto Rico in July 1898, and, on 9 Aug. led the troops in the action at Coamo. He has published ‘Manual of Practical Military Engineering.’

Ernulf, ĕr'nŭlf, or **Arnulf,** English prelate: b. France 1040; d. 15 March 1124. He was appointed prior of Canterbury by Anselm, and was subsequently abbot of Peterborough (1107) and bishop of Rochester (1114). He was equally remarkable for skill in canon law and personal saintliness; and compiled a great collection of documents about his own Church, laws, papal degrees, etc. He is alluded to in Sterne's ‘Tristram Shandy.’

Eroica Symphony, The, a famous symphony by Beethoven, first given at Vienna in 1805, under the title of ‘Bonaparte.’ It was afterward renamed *Sinfonia eroica.* See BEETHOVEN.

Eros, in astronomy, one of the minor planets, discovered photographically by Witt in 1898, at the Urania Observatory, Berlin. The orbits of most of the other known asteroids lie wholly beyond that of Mars; but Eros approaches much nearer to the sun, and at times it may be within 14,000,000 miles of the earth. It is this fact which gives the planetoid its great astronomical interest. The relative dimensions of the solar system are known with high precision, and if any dimension can be accurately measured in miles, all the other dimensions become known at once, in terms of the same unit. It is apparently possible to determine the parallax of Eros (and hence its distance from the earth in miles) with relatively high precision, and a correspondingly accurate determination of the absolute dimensions of the solar system in general will result. As Eros approaches the earth more closely than any other heavenly body except the moon, its parallax is relatively large; and the fact that its diameter is only about 20 miles, so that it appears in the telescope as a mere point of light without a sensible disk, indicates that extremely precise micrometric measures of its position on the heavens may be had. Astronomers are keenly alive to the possibilities offered by this seemingly insignificant little planet, and at every favorable opposition Eros will be studied with exceeding care. It is considered probable that by the end of the century the observations of Eros will have led to a determination of the sun's distance that will not be in error by more than 25,000 miles, the present uncertainty in this distance being probably fully 150,000 miles.

Eros, the Greek equivalent of the Latin Cupid, the god of love. See CUPID.

Ero'sion, or **Denudation,** the process of slow removal in air or water of the products of rock decay whereby the surface features of the earth are obliterated. It includes the destructive work of winds, of streams, of glaciers, and of the ocean. Its various aspects may be considered under three heads, (1) subaërial; (2) marine, and (3) submarine erosion.

1. Under subaërial erosion comes the action of air and water on all land surfaces above sea-level. Changes of temperature crack off flakes from rock-ledges and reduce them to smaller flakes.

Chemical processes, due to moisture and CO_2 in the air, break up the rock-minerals. In a climate with dry seasons the dust may be swept away by the winds (deflation), leaving the larger pebbles. Stony deserts have thus been formed in Arizona and other parts of the world. The dust-charged winds can carve and wear down rock surfaces. Instances are common in the arid regions of the West and in the desert of Sahara.

The erosive action of water begins with the raindrop. If a piece of soft ground with small stones lying about be examined closely after a shower, it will be found that soil has been beaten down and washed away from the areas not protected by stones. This action sometimes takes place on a larger scale in semi-arid climates when rock-decay is slow, and curious pillars of earth or soft rock capped by protecting boulders are formed. Examples may be found in the Garden of the Gods, Colorado. When the raindrops unite to form tiny rivulets the process of river-erosion has begun. In fact, a patch of soft ground on a hillside during a shower shows many of the phenomena of stream-formation, as likewise does even a dust-covered street. The work of surface water is continuous. Some rock-constituents are dissolved and borne away in solution; other particles are carried away in suspension and, by abrasion on rocks below, help the stream carve its channel deeper. When the current slackens some of the waste from the higher lands may be deposited, the coarser materials first. Thus mountains are worn down and plains formed. The higher the mountains, the deeper the valleys can be carved; but even the highest mountains are ultimately deeply dissected, and finally worn down so that the current of the river may not be strong enough to transport the detritus. A country thus worn down is said to have reached a base-level of erosion, and its nearly level surface forms a peneplain. If such a region be uplifted, the streams will start work again vigorously, and a new cycle of erosion will begin. A region reduced to its base-level, if neither elevated nor depressed, can remain unchanged through millions of years.

The amount of waste brought down by some rivers is enormous. Thus the Po in flood carries one part sediment to every 300 parts of water; the Ganges one part sediment to 835 parts of water. These may seen small ratios of sediment, but the total amount of material discharged annually by the Ganges is calculated to be 378,100,000 tons, while the Nile annually brings down 150,000,000 tons. The Mississippi annually brings to the Gulf of Mexico 406,250,000 tons of material in suspension, enough to lower its whole basin one inch in 300 years. It is calculated that the average amount of material removed as sediment annually by streams over the whole land surface is 600 tons per square mile.

Marine erosion includes wave-action; great waves strike heavy blows against projecting headlands, and the surf on rocky beaches charged with boulders and stones is a never-ceasing mill. The undertow of waves sweeps out and rearranges the fine material ground from the rocks; tidal currents, often strong, may bear the waste long distances, or scour channels in soft formations. If a land surface be slowly sinking, the advancing ocean levels the rock ridges and hills. Submarine erosion, the work done by ocean currents, is of little importance, since these currents are seldom strong enough to abrade rocks. The erosive work of ice differs from that of running water in several particulars and is considered (see GLACIER) separately. SAMUEL SANFORD,
Engineering and Mining Journal.

Eros'tratus, Ephesian incendiary. To perpetuate his name as the destroyer of one of the seven wonders of the world, he set fire to the magnificent temple of Artemis (Diana), at Ephesus, on the night Alexander the Great was born (356 B.C.). The indignant Ephesians decreed that whoever pronounced his name would be put to death, a sure means of insuring his fame.

Erot'ic (Greek *erōs*, love), relating to love. — Erotic poetry, amatory poetry.— The name of *erotic* writers has been applied to certain modern French fictionists, and in Greek literature, particularly to a class of romance writers, and to the writer of the 'Milesian Tales.' These writers belong to the later periods of Greek literature, and abound in sophistical subtleties and ornaments. The best of them are Achilles, Tatius, Heliodorus, Longus, Xenophon of Ephesus, and Chariton.

Erpenius, ėr-pē'nĭ-ŭs (Latinized from *Van Erpe*), **Thomas,** Dutch Orientalist: b. Gorkum, Holland, 11 Sept. 1584; d. Leyden 13 Nov. 1624. His fame rests principally on his acquaintance with the Oriental languages. To extend his knowledge of them he visited England, France, Italy, and Germany, and became acquainted with the most eminent scholars. He learned at the same time the Persian, Turkish, and Ethiopian languages. He returned, in 1612, to Leyden, and was appointed professor of Arabic and other Oriental languages. He established a press, at great expense, for the printing of works of Oriental literature. In 1619 a second Hebrew professorship was founded at Leyden, and committed to Erpenius. Soon after he received the office of Oriental interpreter to the States-General. The most learned Arabs admired the elegance with which he expressed himself in their language, so rich in delicate peculiarities. His reputation as a perfect master of the Arabic became universal, and he was repeatedly invited by the king of Spain to explain inscriptions on the Moorish buildings and monuments. The works of Erpenius (some of which were published after his death), are held in the highest estimation. Beside his 'Grammatica Arabica,' his 'Grammatica Hebraica,' and other grammatical works, his most valuable and celebrated publication is his 'Elmacini Historia Saracenica' (1625).

Errante, Vincenzo, vēn-chĕnd'sō ĕr-rän'te, Italian poet and statesman: b. Palermo 16 July 1813; d. Rome 29 April 1891. He was many years an exile for his share in Sicilian politics. His works are two volumes of 'Tragedies and

Lyrics' (1874); the dramas 'The Feast of St. Felix' and 'Suleiman the Great'; the poems 'The Ideal' and 'Liberty.' He wrote also a 'History of the Osmanli Empire from Osman to the Peace of Carlowitz' (1882-3).

Errantia, ĕ-răn'shĭ-a̤, an order of annelids of the sub-class Polychæta, characterized by their not dwelling in fixed tubes, but wandering about freely, seeking animal food. They have a well-developed head, with protrusible pharynx usually armed with chitinous jaws, and efficient locomotary organs. A typical genus is *Nereis,* with many familiar species.

Errard, Charles, shärl ăr-rär, French painter and architect: b. Nantes 1606; d. Rome 15 May 1689. He was instructed in painting by his father, and perfected his knowledge at Rome. On his return to France he gradually rose to eminence in his profession. In 1648 he became one of the 12 founders of the Academy of Painting. He was engaged in the decoration of the Palais Royal, Louvre, and other palaces. His chief claim to notice rests, however, upon his connection with the foundation of the French academy at Rome, which was projected by him and carried into effect in 1666, with 12 pupils.

Errata, ĕ-rā'ta (Latin, the plural form of *erratum,* an error), the list of errors and corrections placed at the end or at the beginning of a book. Before the invention of printing, and for a short time after, the errata were corrected on the page where they occurred, but this was found to be inconvenient when the art became a little more developed. The first known example occurs in an annotated edition of 'Juvenal,' published at Venice in 1478, which contains a list occupying two pages. 'The Vulgate,' published in 1590, at Rome, by Sixtus V., and of which the proofs were revised by that Pope himself, contains, instead of a table of errata, a bull which excommunicated those who would dare to make any alterations in the text. The book, however, was found to contain so many blunders that it was afterward suppressed, and the Papal bull had no other effect than that of amusing the learned and creating a demand for the copies still existing, some of which have been sold for about $200. See Bull; Mistake.

Errat'ics, or **Erratic Blocks,** in geology, boulders or large masses of angular rock which have been transported to a distance from their original mountains by the action of ice during the Glacial Period. Thus on the slopes of the Jura Mountains, in France, immense blocks of granite are found which have traveled 60 miles from their original situation. See Geology; Glacier.

Errera, Alberto, ăl-bĕr'tō ĕr-rā'rä, Italian political economist: b. Venice 21 April 1841. He was educated at Padua and has held the professorship of political economy and statistics in the schools of several Italian cities, including Venice, Milan and Naples, and also at the University of Naples. Among his works are: 'Storia e statistica delle industrie venete' (1870); 'Storia delle economia politica nei secoli XVII. e XVIII. negli stati della repubblica Veneta' (1877); 'Demographia' (1892); and 'Lezione di economia politica' (1892).

Er'rett, Isaac, American clergyman: b. New York 2 Jan. 1820; d. near Cincinnati, Ohio, 19 Dec. 1888. In 1840 he entered the ministry of the "Christian Church," a sect founded by Alexander Campbell, and held pastorates in Pennsylvania, Ohio, Michigan, and Chicago, Ill. For a time, he assisted Campbell in the editorship of the 'Millennial Harbinger,' in 1866 he established the 'Christian Standard,' and published it until his death. He was president of Alliance College 1868-9; filled many offices in his Church, and wrote: 'Brief View of Christian Missions' (1857); 'First Principles, or the Elements of the Gospel' (1867); 'Letters to a Young Christian' (1877); 'Evenings with the Bible' (1884-7); 'Our Position; the Plea Urged by the People Known as Disciples of Christ' (1885), etc.

Error, (1) In astronomy, errors or differences in calculations and observations, to correct which recourse is had to a system of reduction known as the method of least squares. (2) Clerical error, a mistake in writing, a slip of the pen. (3) Joiner in error, in law; the taking of issue on the suggestion of error. (4) Writ of error, in law, a process issued by a court of review, to an inferior court, suggesting that error has been committed and requiring the record to be sent up for examination; now commonly known as an appeal. (5) Court of error, a court exercising appellate jurisdiction by means of writs of error. (6) Assignment of error, in law, specification of the error suggested or objected to. For ordinary errors, see Bull; Mistake.

Error, Personal. See Equation, Personal.

Ersch, Johann Samuel, yō-hän sä'moo-ĕl ersh, German bibliographer: b. Grossglogau 23 June 1766; d. Halle 16 Jan. 1828. He was principal librarian and professor of geography and statistics at Halle. Among his publications are: a 'Dictionary of French Writers'; 'Manual of German Literature'; and, in connection with Gruber, the 'Universal Encyclopædia of Arts and Sciences' (1818).

Erse, ėrs, a corruption of the word Irish; a name applied to Irish Gælic people, and also to the lowlanders of Scotland. See Celtic Language and Literature.

Erse Language. See Celtic Language and Literature.

Erskine, ėrsk'ĭn, **Ebenezer,** Scottish clergyman, the founder of the Secession Church in Scotland; b. Scotland 22 June 1680; d. Stirling, Scotland, 2 June 1754. He was ordained minister of Portmoak, in Fife, in 1703, in which situation he continued for 28 years, when he removed to Stirling. His attitude toward patronage and other abuses in the Church led to his being deposed, when, in conjunction with his brother and others, he founded the Secession Church. He was the author of several volumes of sermons. See MacEwen, 'The Erskines' (1900).

Erskine, Henry, Scottish barrister: b. Edinburgh 1 Nov. 1746; d. Ammondell, West Lothia, 8 Oct. 1817. He twice held the office of lord-advocate, was for long the leader of the Scottish bar, and had a high reputation as a wit.

Erskine, John, of Carnock, afterward of Cardross, Scottish jurist: b. 1695; d. near Dumbarton 1 March 1768. He was called to the Scotch bar in 1719, and was author of 'Principles of the Law of Scotland,' and the 'Institute of the Law of Scotland,' both authorities.

Erskine, Ralph, Scottish clergyman: b. 15 March 1685; d. Dunfermline 6 Nov. 1752. He was a brother of Ebenezer Erskine (q.v.). He was ordained to the parish of Dunfermline in 1711, and in 1737 joined his brother, who had seceded from the Established Church. His 'Gospel Sonnets' and other religious works were once very popular.

Erskine, Thomas, Baron Erskine, Scottish jurist: b. Edinburgh 21 Jan. 1750; d. there 21 Jan. 1823. He became a noted forensic orator and jurist, attaining most of his renown as a pleader in support of the accusations of corruption made against Lord Sandwich; later he added to his success by his defense of Stockdale, Hardy, Thomas Paine, Horne Tooke and others. He was a member of the House of Commons in 1790–1806. He was created Baron Erskine of Restormel, on becoming lord chancellor.

Erup'tion, a term applied to a local disturbance in the skin characterized by the formation of redness or scaliness, blistering or pustulation. In one class of affections, known as the eruptive fevers, a characteristic form of skin-eruption is diagnostic. Thus the fine red rash of scarlet fever, the bluish red rash of measles, the irregular rash of chickenpox and the pustulate rash of smallpox are readily recognized. The popular notion that an eruption is an indication of something evil within the body finding its way out belongs to the mediæval days of superstition and ignorance, when disease was regarded as an evil spirit to be exorcised, and gave notice of its evacuation by means of an eruption on the skin. At the present time we know that most eruptions are either of purely local occurrence, due to localized irritants, as in the case of pimples, boils, etc., or that they represent a disturbance of the nerve-centres, whose end-filaments are distributed to the epithelial structures of the body. Thus in measles, not only the skin, but also the mucous membranes of the respiratory tract are affected, the poison affecting the nerve-structures being evidenced by nerve-irritation at the periphery of the body. The popular idea that it is necessary to bring an eruption out in acute infectious diseases such as measles, scarlet fever, etc., is a trustworthy one, but an interpretation is frequently given to it that is not sound. The presence of an eruption on the surface of the body in these affections is an indication of the protective energies of the human organism in its fight with the infection and poisoning. The inability of the body to counteract the poison of the disease may prevent the development of the eruption, and thus its bringing out, being the sign of the body's ability successfully to cope with the poison, is the warrant for the popular idea of the efficiency of the eruption. Many drugs locally applied, or taken internally, cause the formation of eruptions. These eruptions may be due to purely nervous influences, or they may be of local origin. Drug-eruptions following the use of the iodides and bromides are of this latter character. As the drug is eliminated through the skin, its passage there causes local irritation and the formation of an eruption. See Dermatitis; Measles; Skin.

Erup'tive Rocks. See Igneous Rocks.

Erwin von Steinbach, ĕr'vēn fōn stīn'baн, German architect: b. Steinbach, Baden; d. 17 Jan. 1318. The principal tower of the cathedral of Strasburg had been completed in the 7th century. It was partly built of wood, and was reduced to ruins by lightning and successive fires. The nave, begun in 1015, was only completed in 1275. Erwin was then requested to furnish designs for the decoration of the interior of the church, and for the construction of two new towers and a façade upon the site of the ruins of the old tower. The foundation stone of the new structure was laid 25 May 1277. The architect died when the work was only half finished; it was continued by his son Johannes (died 18 March 1339), and subsequently continued chiefly after his designs, still preserved at Strasburg. His daughter Sabina assisted him in the decoration of the interior of the church; and another of his sons, Winhing (d. 1330), was also an architect of some distinction. The remains of this family of architects are interred within the cathedral.

Eryman'thus, in ancient geography, a river and mountain of Arcadia, in Greece. The river, according to some the modern Dimitzana, rises on the frontiers of Arcadia and Elis, and flows into the Alpheus. The mountain, situated to the east of the river, formed the western point of the northern barrier of Arcadia, and was covered with forests. It was in this mountain that Hercules chased and killed the famous wild boar.

Eryngium, e-rĭn'jĭ-ŭm, a species of plants of the carrot family (*Umbelliferæ*). The generic name from the Greek refers to their thistle-like appearance. There are about 150 species in the genus, of which 22 are found in America. Rattlesnake-master, or button-snakewood (*E. aquaticum*) grows in wet soil and in the pine-barrens, from New Jersey south to Florida and west to Texas, Missouri, and Minnesota. Its common names are given to it because of its supposed efficacy as an antidote to the venom of snakes. A number of species are cultivated, both on account of the steel-blue color of the stem and branches, and of the unusual manner of growth. Eryngo (*E. maritimum*), sea-holly, is a native of England. It frequents sandy shores, and is distinguished from other plants of the order by its rigid, spiny, glaucous, veined leaves, and its dense heads of blue flowers. The roots are sometimes candied, and are reputed to be stimulating and restorative. Falstaff speaks of its use as a confection and its aphrodisiac qualities, either real or supposed, are mentioned by dramatists from Jonson to Prior.

Eryops, ĕr'ĭ-ops, a large fossil labyrinthodont amphibian, characteristic of the Permian Period in North America. The skull is 18 inches to 2 feet in length, very flat and broad.

Erysichthon, ĕr-ĭ-sĭk'thŏn, a legendary king of Thessaly, who, being guilty of sacrilege against Ceres, devoured his own flesh.

Erysimum, ĕ-rĭs'ĭ-mŭm, a genus of plants of the natural order *Cruciferæ*, chiefly biennials, with narrow entire leaves, and yellow, often fragrant, flowers. There are about 85 species, natives of northern temperate and cold countries. *E. cheiranthoides*, a native of Europe, with small yellow flowers, is found in waste places, along streams, and in fields from southern New England to Newfoundland, and westward to the

Pacific coast. The seeds of this plant were formerly employed as an anthelmintic, hence the name of wormseed. It is also called treacle-mustard, because used as an ingredient in the famous Venice treacle. The seeds of *E. perfoliatum* are used as a source of oil in Japan. Many of the plants formerly assigned to this species are now grouped in other genera, as *Sisymbrium*, etc.

Erysip'elas, an acute infectious disease of the skin and subcutaneous structures caused by a streptococcus. Whether the *Streptococcus erysipelatis* of Fehleisen, or the *Streptococcus pyogenes* is considered the causative factor or not, the fact remains that bacteriologically it is probable that these two forms of bacteria are identical. The reaction of the tissues to the streptococcus and its poisons causes the acute inflammation with redness, puffiness, and sometimes gangrene. This local swelling is attended with fever, headache, general constitutional symptoms, nausea, vomiting, and at times with toxic delirium. Occasionally the streptococcus wanders into the blood-stream, and general septicemia or pyemia results. At other times a streptococcic invasion of the joints produces an acute rheumatism with secondary heart complications. Erysipelas may affect any part of the body, but is very frequent over the face and head. It is extremely contagious, the organism finding entrance through minute wounds. Patients who have had recent erysipelas should on no account be allowed to come anywhere near women in childbirth, as puerperal fever may result. The treatment of erysipelas is by means of tonics — iron and quinine being favorites — nutritious and easily assimable diet, milk, cod-liver oil, and some form of alcohol. In those patients in whom abscess formation occurs, prompt surgical evacuation is imperative. Local treatment by ichthyol and similar antiseptics is widely employed with some benefit.

Erythe'ma. See DERMATITIS.

Erythræan (ĕr-ĭ-thrē'an) **Sea,** in ancient geography, a name given to what is now called the Indian Ocean, but including the Persian and Arabian gulfs. The name was latterly restricted to the Arabian Gulf.

Eryth'ric Acid is obtained from lichens by extracting with boiling water or milk of lime. It is a white, crystalline, tasteless, and odorless powder, readily soluble in alkalies, and alcohol. See CHEMISTRY.

Erythrina, ĕr-ĭ-thrī'na. See CORAL-TREE.

Erythrite, e-rith'rīt, or "cobalt bloom," a native hydrous cobalt arsenate, having the formula $Co_3As_2O_8 + 8H_2O$. It has a beautiful peach-blossom red color, whence its name from the Greek, *eruthros*, red. It occurs in monoclinic crystals, but more commonly in globular or stellate masses or earthy. It occurs at Schneeberg, Saxony; in Cornwall, England; in Chile, and in some parts of the United States.

Erythro'nium, a genus of small plants of the lily family, common in damp, shady woods, of which a well-known and widespread species (*E. americanum*) in the United States, is the "dog-tooth violet" or "adder's tongue" — both unfortunate names. It is among the earliest of spring flowers, appearing as two radical leaves, usually handsomely mottled, between which rises a slender, naked stem (scape) three to four inches high, bearing a single bell-shaped flower of six distinct lanceolate petals, pale yellow, often spotted near the base. Some eight other species are known in the United States, some bearing several flowers on the scape, and of various tints, as purple, rose-color or pinkish white.

Erythrophlœum, ĕ-rĭth-rō-flē'um, a genus of tropical trees, of the pea family, containing three species, two found in Africa, and the third in Australia. The *E. guineense* of Africa has a poisonous red juice, which is used by the natives as a test of innocence or guilt, and hence the name ordeal-tree. The natives of Guinea and the Gold Coast employ the same juice to poison the points of their arrows.

Erythroxylon, ĕ-rĭth-rŏk'ĭ-lŏn, a genus of plants of the natural order *Erythroxylaceæ*. The family contains 30 species, composed almost exclusively of trees and shrubs; growing in tropical South America. The flowers are small and lack color; the fruit is a drupe. The red dyewood of Brazil is *E. suberosum*, and the oil-wood of Mauritius is *E. hyperiifcolium*. The chief member of the genus and family is *E. coca*. See COCA.

Eryx, ē'rĭks, ancient name of a city and mountain in the west of Sicily, about six miles from Drepanum, and two from the seacoast. The mountain, now Monte San Giuliano, rises direct from the plain, unconnected with any other range, and hence possesses a much greater altitude in appearance than in reality, its height being only 2,184 feet. It was anciently believed to be the highest mountain in the island after Etna, and is frequently alluded to by Virgil and other poets. On the summit stood a celebrated temple of Venus, from which the goddess received the epithet of Venus Erycina. All traces of the ancient town of Eryx have now disappeared, and its site is occupied by the modern town of San Giuliano; but some remains of the temple still exist in part of the substructure of the castle.

Erzerum, ĕrz'room, **Erzeroum,** or **Erzeroom,** Turkey, a city of Armenia, and, since the annexation of Kars by Russia, the chief strategical centre and place of resistance to a Russian advance, about 100 miles southwest of Trebizond. Its fortifications have been repaired and much improved since 1864. The inhabitants consist of Turks, Armenians, and Persians, are very industrious; and, in addition to important manufactures, especially in copper and iron, carry on a very extensive trade. This is greatly favored by the position of the town, standing at the junction of several important roads leading from Transcaucasia by way of Trebizond, and communicating with different parts of Asia Minor, with Persia, Kurdistan, Mesopotamia, etc. The value of British goods imported into the town in 1898 was estimated at $244,000. Erzerum is a place of great antiquity. Anatolius, commander of the Emperor Theodosius II., here built the citadel of Theodosiopolis, northwest of the open Syro-Armenian trading town of Arsen. On the destruction of this town by the Seldjuks, in 1049, the inhabitants removed to Theodosiopolis, which received from them the name of Arsen-er-Rum, that is, Arsen of the Romans. Hence the modern name Erzerum. In 1241 it fell into the hands of the Mongols, and in 1517 into those of the Turks, notwithstanding whose mismanagement it continued to be the most important commercial emporium of the Armenian plateau, and had a population of 100.000. In 1829 it was taken by the Russians, but was restored to Turkey by the Peace of Adrianople. Many of the inhabitants, however, quitted the town and settled in the Russian territory. In the winter of 1877 it was besieged by the Russians, who reduced the defenders by famine, until in February 1878 it was surrendered, and held by the Russians for several months. It was again, however, restored to the Turks. Pop. (1901) 38,500.

Erzgebirge, ĕrts'gĕ-bĕr-gĕ, a range of low mountains about 100 miles long on the boundary between Saxony and Bohemia. The mountains, like the Blue Ridge Mountains in the United States and the Highlands of Scotland, are an ancient range, worn down and again uplifted. As the name (Ore Mountains) implies, the Erzgebirge contain valuable deposits of minerals and form an old mining region. Silver ores were mined there as long ago as 1150 and mines of lead, copper, tin, cobalt nickel and iron ore have also been sunk there.

Esarhaddon, ē-sär-hăd'ŏn, Assyrian ruler: d. about 667 B.C. He was the son of Sennacherib, one of the most powerful of the Assyrian monarchs. He extended the empire on all sides, and is the only Assyrian king who actually reigned at Babylon.

Esau, the eldest son of Isaac, and twin brother of Jacob (Gen. xxv. 24–6). His name (which signifies rough, hairy) was due to his singular appearance at birth, being "red, and all over like an hairy garment." The struggle for precedence between the brothers was foreshadowed the moment of their first appearance in the world. Esau, the father's favorite, became a cunning hunter; Jacob, the favorite of the mother, became a peaceful shepherd. One day, as Esau returned famished from the chase, he found his brother preparing some lentil pottage, and asked for a share of it. Jacob, taking advantage of his brother's distress, offered him the pottage if he would give up his birthright. Although this meant yielding up the headship of the tribe and the greater share of the family property, Esau nevertheless consented. He was named Edom (red) in consequence, from the color of the pottage; and the name was given to the land he settled in. The next episode in his history is when Jacob, instigated by his mother, personated Esau, and succeeded in getting his father's covenant blessing. The indignation of Esau at the base trick was natural; and Rebekah sent Jacob out of the way for a time, to escape his brother's vengeance. On his return from a protracted stay Jacob succeeded in mollifying Esau by presents and flattery. After a subsequent meeting of the brothers, on the death of their father, we hear no more of Esau.

Esbjerg, ĕs'byĕrg, Denmark, seaport, 56 miles west of Fredericia, with a large export trade in cattle, and dairy products, mostly to England. Its harbor, the only one of importance on the west coast of Jutland, was constructed by the state at great expense in 1868–74; and in 1887 an annual subsidy was granted by government for steam communication with Great Britain. Pop. (1901) 13,365.

Escalade, ĕs-kā-lād', in war, a furious attack of a wall or a rampart, carried on with ladders, to pass the ditch or mount the rampart, without proceeding in form, breaking ground, or carrying on regular works to secure the men. See WAR.

Escalator, the name applied to a continuous carrier designed for conveying passengers from one level to another within a limited time. The various units making up the escalator are so arranged that on the incline they present the familiar zigzag appearance of an ordinary stairway, and may be used as such. The escalator consists of an endless series of steps connected together by a heavy sprocket chain which, at the proper place, engages with the driving sprocket wheel. Each step is essentially a four-wheel truck, bolted to a shaft, which in turn, is connected to the links of the driving chain. There are two wheels at each end of the truck traveling on separate tracks, so placed that the steps remain horizontal at all points of the ascent. At the landing, at the top and the bottom of the escalator, the trucks travel in the same plane so that the steps there become a moving platform. Ample opportunity is thus given, even to the infirm, to board the device before the ascent begins and, at the top to step off again. A traveling hand-rail moving at the same speed as the steps further simplifies its use. Should a person fail for any reason to step off at the upper landing, a device called a shunt, removes him from it. This consists of a box-like affair, triangular in plan, placed about 10 feet from the top of the escalator with the apex pointing against the direction of the moving platform. In the lower part, set in a vertical position are two belts running backwards from the apex. Anything coming in contact with these belts is gently brushed to one side. Every part of the escalator is made to micrometer measurements to one thousandth of an inch by special machinery designed for the purpose. As a result of this unusual precision, the various steps fit together so nicely that a piece of paper cannot be forced between them. To secure practically noiseless operation, the wheels on which the trucks move are deadened, rawhide pinions are used in driving gear, and the tracks are built up of wood and steel. The links of the sprocket chain are made of two 18 inch cast steel shrouds, with 1½ inch steel pins between them at 3 inches between centres. The ends of the links are bushed with phosphor-bronze in which graphite is inlaid, thus providing lubrication of the bearing surfaces, and the wheels are similarly provided with a constant lubrication of graphite. The escalator is driven by an electric motor located within the structure of the upper landing and suitably geared to the large driving sprocket wheel by a combination of worm and spur gearing. All parts of the running gear are made of crucible cast steel, the axles and link pins being of cold drawn steel. Each casting is subjected to a test of many times the working-strain to come upon it.

While there are no mechanical limitations to the rate of speed with which the escalator may be driven, it has been found that a speed of about 100 feet per minute is satisfactory to the public. At this rate of driving, 4,000 steps per hour arrive at the landing and the maximum capacity of the machine depends upon the width of the steps used. The escalators which have been installed for railroad stations, large department stores and other localities where a large capacity is necessary, have been a little over five feet in width and as each step readily accommodates three people the maximum capacity of such a construction is 12,000 people per hour. For the smaller department stores and for use in railroad stations where the traffic is not heavy the escalator is made of such width as to accommodate one person on each step, and the capacity is therefore 4,000 per hour. It should be noted that the escalator is a perfectly reversible machine, operating equally well in either direction. In the «duplex» type, the steps during the descent are again guided into the familiar zigzag position by suitably placed tracks and thus the same machine serves to carry passengers both up and down. In a third modification of the device designed especially for the London underground railroads, where the difference between levels is considerable, the steps ascend in one spiral and descend in another spiral below the first.

Charles D. Seeberger.

Escanaba, ĕs-ka-nä'ba, Mich., city, county-seat of Delta County, on Little Bay de Nouquette, an inlet of Green Bay; on the Chicago & N. W., and the Chicago, M. & St. P. R.R.'s; 52 miles northeast of Marinette. It is the grain and vegetable raising and lumbering centre of the country and an important iron-shipping point; it has five docks for iron ore, and an excellent dock for the shipping of other products. It has a public high school, St. Joseph's high school, public library, daily and weekly newspapers, and a national bank. Pop. (1901) 9,549.

Escandon, Guillermo de Landa y, Mexican statesman: b. Mexico City. He was educated in Stonyhurst University, England; was several years a member of the national senate, representing the states of Chihuahua and Morelos; from 1900–02 was mayor of Mexico City; and became governor of the Federal District in 1903. Under his administration many very important reforms have been introduced and carried to successful results, among them the restriction or practical discontinuance of gambling; the improvement of the public carriage service; the enactment of rules restricting the speed of automobiles; the protection of the Peon or Indian class; the improvement of the prisons of the capital city and its suburbs, and also of the public buildings and military barracks; the bettering of the sanitary condition of the correctional schools, the theatres and other places of amusement, and of the entire city; the adoption of a system of street sweeping and sprinkling; the placing of proper restrictions on the sale of alcoholic beverages, etc.

Escape'ment, a part of the machinery in a watch or clock. See Clock; Watchmaking.

Escarp'ment, the abrupt descent, which may or may not be a cliff, from a plateau to lower land. See Mountain; Cliff.

Escars. See Eskers.

Eschaiot, esh-a-lŏt'. See Shallot.

Eschatology, ĕs-kā-tŏl'ō-jĭ (Gr. *eschatos*, «last,» and *logos*, «a discourse»), the doctrine of the last things, a theological term for what Scripture reveals and Christian speculation has concluded about a future state. But although the term is thus limited, an eschatology existed among all the great nations of antiquity, dark and ill defined as in the Greek, or elaborate as in the Egyptian religion. Together with it grows up more or less definitely the idea of retribution. See Theology.

Escheat', the reversion of property to the sovereign. The law considers that all property must have an owner; so if a person die intestate and without issue, the property, in England, escheats to the king, and in America to the State as sovereign. In some jurisdictions, before the sovereign receives title there is a certain kind of proceeding to determine whether or not there are any heirs, while in other jurisdictions the sovereign gets the title on the death of the owner; but even in these cases the sovereign's title is defeasible until there are proceedings to determine that the deceased had no heirs. When the sovereign obtains title by escheat it acquires all the rights and privileges of the last owner, and the statutory requirements must be strictly followed, both as to the disposal of the property and as to the use of the fund derived from the sale, in case a sale is necessary. In the United States the powers and duties of the sovereign in relation to escheated property are controlled by statute in the different states.

Eschenbach, Wolfram von, vōlf'räm fōn ĕsh'ĕn-bäн, German mediæval poet: b. Eschenbach, near Ansbach, Bavaria; d. about 1220. He was one of the most prominent minstrels at the court of Hermann, Landgraf of Thuringia; and his epics rank among the greatest German imaginative works. Besides several love songs he wrote 'Parzival'; 'Wilhelm von Orange,' and 'Titurel, or the Guardian of the Graal.'

Eschscholtz, Johann Friedrich, yō'hän frēd'rĭн ĕsh'shōlts, Russian naturalist: b. Dorpat, government of Riga, 12 Nov. 1793; d. there 19 May 1834. He studied medicine in his native city, and in 1819 became professor of anatomy and director of the zoological museum of the University of Dorpat. In 1815–18 and 1823–6 he accompanied Otto von Kotzebue in the latter's exploring tours around the world, collected a large number of natural history specimens, and made valuable scientific studies on the lower organisms of deep-sea life. The results of his studies were published in Kotzebue's account of the expedition (1821), and he presented his collections to the University of Dorpat 1826. His catalogue of over 2,000 animals was published in Kotzebue's 'Neue Reise um die Welt' (Vol. II. 1830). Adelbert von Chamisso, another member of these expeditions, named a botanical species *Eschscholtzia* in his honor, and Eschscholtz Bay, on the Alaska coast, is also named after him. He published: 'Ideen zur Aneinanderreihung der rückgrätigen Tiere' (1819); 'System der Akalephen' (1829); 'Zoologischer Atlas' (5 parts, 1829–33), containing plates and distributions of new species of animals.

Eschscholzia, ĕ-shōlt'sĭ-a, or **California Poppy,** a genus of annual and perennial herbs of the natural order *Papaveraceæ,* natives of the Pacific slope of the United States. The species, of which there are about a dozen, are distinguished by much dissected alternate leaves, yellow or white showy flowers (the sepals united to form a deciduous hood), and a long capsular fruit resembling a silique. The best-known species is probably *E. californica,* a perennial which is widely cultivated as an annual in flower gardens, and is a beautiful orange-colored flower, one of the most showy in the whole floral kingdom. It is gregarious in habit, and in California it covers large areas with an almost unbroken orange-yellow bloom of striking beauty when seen on the gray-green slope of a treeless hillside. It is easily raised, especially if the seed be sown soon after gathering in the fall, and the young plants protected in cold climates with a light mulch of straw or leaves. Spring-sown seed is usually less satisfactory since it is less viable. The name is erroneously spelled "Eschscholtzia."

Eschwege, ĕsh'vā-gĕ, Germany, a town of the Prussian province of Hessen-Nassau, on the Werra, 26 miles east-southeast of Cassel. It is a walled and well-built town, with a castle, long the residence of the landgraves of Hessen-Rotenberg, but now used as a public building. It has manufactures of woolen and linen cloth, several large tanneries and glue-works, oil and other mills, and a trade in meal, fruit, lard, ham, and sausages. Pop. 11,341.

Eschweiler, esh'vī-lĕr, Germany, town in the Prussian Rhine province, nine miles east-northeast of Aix-la-Chapelle, at the confluence of the Inde and Dente. It has manufactures of articles in iron and tin-plate, zinc and copper, machinery, boilers, railway plant, needles, wire, rolling-mills, smelting furnaces, etc. Calamine and lead, as well as productive coal-mines, are worked in the vicinity. Pop. 22,654.

Es'chynite. See ÆSCHYNITE.

Escobar y Mendoza, Antonio, än-tō'nē-ō ĕs-kō-bär' ē mĕn-dō'thä, Spanish casuist: b. Valladolid 1589; d. 4 July 1669. Entering the order of the Jesuits in 1604, he became celebrated as a preacher and writer. At his death he left more than 40 volumes in folio, mostly in theology and morality, the principal being the casuistical 'Liber Theologæ Moralis' (1646), which has several times been printed.

Escobedo, Mariano, mä-rē-ä'nō ĕs-kō-bā'-dō, Mexican soldier: b. Dos Arroyos, New Leon, 12 Jan. 1827; d. Tacubaya 22 May 1902. When the war between Mexico and the United States broke out he was a muleteer in charge of a string of pack mules belonging to his father. He converted his muleteers into a band of guerrillas, attacked small detachments of the American troops wherever he found them, and took part in the battles of Palo Alto and Resaca. Juarez commissioned him colonel in 1859. In 1861, upon the establishment of Juarez' government in the City of Mexico, Escobedo was made a brigadier-general and sent in pursuit of the Clerical forces under Marquez and Mejia, but was surprised, taken prisoner after an heroic defense, sentenced to be shot, but escaped and returned to Juarez. He took a prominent part in the engagements with the French which followed the intervention of Napoleon III. in Mexican affairs. He repulsed them at Puebla 5 May 1862, took part in the long siege of that place, and when it was captured by the French 17 May 1863, was taken prisoner, but succeeded in escaping. When Maximilian's empire was established, Escobedo took up his headquarters in Texas, secretly purchased arms and ammunition in New Orleans, 1865, organized and equipped a force of Mexican refugees, American negroes, and ex-Confederate soldiers, led them into Mexico, captured the imperial garrison at Monterey November 1865, and swept everything before him. Juarez appointed him commander-in-chief of the Army of the North; he continued his victorious course until all the chief cities were in the hands of the republicans, and finally besieged and defeated the emperor at Queretaro 15 May 1866. It is said that Maximilian offered his word of honor to Escobedo, on surrendering his sword, to leave the country at once if conducted to the nearest port; but Escobedo refused, ordered a court-martial to be instituted, and the emperor was condemned and executed. In 1874 he quelled an uprising against the government of Juarez, but was unsuccessful in putting down the revolution started by Gen. Diaz. He fled to Texas, issued a manifesto against Diaz, returned, was arrested and tried, and notwithstanding the government's efforts to convict him, was acquitted. To escape petty persecutions he went to New York 1879–80, but returned, and was appointed president of the supreme military court of justice 1882–3, when he retired at last to private life.

Esco'rial, or **Escu'rial,** a royal palace of Spain, distant from Madrid about 24 miles in a northwesterly direction, and situated on the acclivity of the Sierra Guadarrama, the range of mountains which divides New from Old Castile. The Escorial combines a monastery, a church, and a mausoleum with a royal palace. Everything about the Escorial — situation, plan, and purposes — bears the stamp of the singular and unpractical mind of its originator, Philip II. Not the least remarkable of its peculiarities is its site. Away from cities, amid the seclusion of mountain scenery, it stands at a height of 2,700 feet above the level of the sea. It was built in commemoration of the battle of St. Quentin, which was fought 10 Aug. 1557. The building is a rectangular parallelogram measuring 744 feet in length by 580 in breadth. The interior is divided into courts; while a projection 460 feet in length contains the chapel and the royal palace. The building was begun in 1563 by Juan Bautista de Toledo, a Toledan architect, and finished in 1584 by his pupil Juan de Herrera. It is irregular in its proportions, and thus loses much of the effect which, from its great magnitude, it ought to have. The innumerable windows (said to be 11,000 in honor of the Cologne virgins) give it the aspect of a large mill or barrack. The doors are also numerous. The material of the building is gray granite found in the neighborhood, which preserves its fresh and clean appearance. The church, situated immediately in front of the palace, is 320 feet long and 230 broad; and under it is the Pantheon or burying-place of the kings of Spain. Its interior is lined with dark marble beautifully veined. The monasterial part of the building contains a valuable library, especially rich in Greek and Arabic manuscripts, and there is a superb collection of pictures scattered through various parts of the building. Raffaele, Titiens, Rubens, Velasquez, Guido, and other great masters are here represented. During the French occupation the books, 30,000 in number, were removed to Madrid, but were sent back by Ferdinand minus 10,000 volumes. The Escorial was partly burned in 1671, when many MSS. were destroyed. It was pillaged by the French in 1808 (when the books were removed) and in 1813. It was restored by Ferdinand VII., but the monks, with their revenues which supported it, have long since disappeared, and the building, which from its situation requires to be kept in repair at considerable expense, has fallen into some decay, though repairs are executed from time to time. On 2 Oct. 1872 it was struck by lightning, and was in consequence seriously injured by fire. The monastery portion of it is now a seminary in which youths receive a secular education. The Escorial is 32 miles by railway from Madrid.

Escort, a guard, a body of armed men which attends an officer or baggage, provisions or munitions, conveyed by land from place to place, to protect them. This word is sometimes used for naval protectors; but the proper word in this case is convoy. In the United States escorts are of two kinds, funeral escorts and escorts of honor. The army regulations fix the character and size of escorts according to the military prominence or title of the individual.

Escosura, Patricio de la, pä-trē'thē-ō dā lä ĕs-kō-soo'rä, Spanish novelist and poet: b. Madrid 5 Nov. 1807; d. there 22 Jan. 1878. After various political and military ups and downs and being twice exiled, in 1855 he was sent as a special envoy to the Portuguese court, became under-secretary of state, minister of the interior, and afterward ambassador to Germany, 1872–4. He wrote the historical novels: 'The Count de Candespina' (1832); 'Neither King nor Pawn' (1835); and 'The Patriarch of the Valley'; the epics 'The Bust in Black Cloak' and 'Hernan Cortés at Cholula'; several dramas, the most successful of which was 'Hernan Cortés' Debaucheries'; and several historical works, among them a 'Constitutional History of England' (1859).

Escott, Thomas Hay Sweet, English journalist: educated at Queen's College, Oxford, and since 1865 actively connected with London journalism. He has been a leading article writer for the 'Standard' since 1866 and succeeded John Morley (q.v.) as editor of the 'Fortnightly Review.' He has published: 'England: Its People, Polity and Pursuits' (1897); and its sequel, 'Social Transformations of the Victorian Age' (1897); 'Politics and Letters' (1886); 'Lord Randolph Churchill: a Monograph' (1895); 'Personal Forces of the Period' (1898); 'A Trip to Paradoxia' (1899). He has also published an edition of 'Juvenal and Persius.'

Escuage, ĕs'kū-āj. See SCUTAGE.

Escuer'zo, a Spanish term for "toad," specifically applied in the valley of the La Plata to a large local toad-like frog (*Ceratophrys ornata*) noted for its varied colors, laid on like those of a Persian carpet. This patchwork thoroughly conceals them as they lie half-buried in the ground. "If there is not enough green vegetation," says Gadow, "they throw, with their feet, little lumps of earth upon their backs, the skin of which becomes at the same time more wrinkled and assumes duller tones. There the creature lies, perfectly concealed, betrayed only by the metallic, glittering eyes, waiting for some unfortunate creature to pass into the trap represented by the enormous mouth, which opens and shuts with lightning rapidity and an audible snap." These frogs are of the Cystignathine group (see FROG) and closely allied to the monstrous "horned toads" of Brazil. They live chiefly on frogs and are sometimes cannibals.

Escuintla, ĕs-kēn'tlä, Guatemala, one of the southern departments of that republic; population about 32,000. Its chief town, also called Escuintla, situated at an altitude of 1,269 feet above the level of the sea, on the line of the Central Railroad and half way between Guatemala city and the port of San José, has good hotels and apartment houses, and is a favorite winter resort. Pop. of Escuintla city about 12,350.

Es'culin, Es'culine. See ÆSCULIN.

Escutcheon, ĕs-kŭch'ȯn, in heraldry, is derived from the Old French *escusson,* French *écusson,* and that from the Latin *scutum,* a shield. It signifies the shield whereon coats of arms are represented. See HERALDRY.

Esdraelon, ĕs-drā-ē'lŏn or ĕs-drā'e-lŏn (Merdj-Ibn-Amer), the famous and beautiful plain in Palestine, situated between the mountains forming the western watershed of the Jordan and the Mediterranean Sea. Other names by which it is called in the Old Testament are Jezrael, valley of Megeddo, and the Great Plain. It is triangular in form, 36 miles in length, with an average width of 15 miles. On its boundary are: on the northeast Mount Tabor, the southeast Mount Gilboa, and on the southwest Mount Carmel. The principal streams are Nahr-el-Djalood, which flows into the Jordan, and the Kishon (Nahr-el-Moukataa) which flows into the Bay of Acre just north of Mount Carmel. Other streams traverse the plain, but are chiefly branches of the two streams mentioned. The soil is fertile and when cultivated with care yields good crops. When Esdraelon was traversed by caravans crossing Palestine from the rich countries east and west, grains, vegetables, and fruits were raised in abundance. Agriculture is again receiving attention. Some of the noted places on this plain are Djeneen (probably the old town of Engannin), at the entrance to the plain and 984 feet above the sea. Tradition says this is where the 10 lepers were cured (Luke xvii.); Zerlin, known by the residents as Zeraeen, called by the Crusaders Petit-Guérin, is now a large village. Near it is the fountain, Ain-Maeeteh, supposed to be where Saul camped when at war with the Philistines (1 Sam. xxxi). Ain-Djalood, said to be the place where Gideon selected the 300 men who fought and defeated the Midianites (Judge vii.). On the south side of the Kishor are the villages of Afooleh, El-Fooleh and Zerin. Afooleh is the old town of Aphec, one of the places where the Assyrians and Egyptians met in battle. At El-Fooleh was once a fortress built by the Templars, but destroyed by Saladin in 1187. Here was fought the battle between the French under

Napoleon, 4,000 in number, and the Mohammedans, 35,000 in number, in which the French were victorious. Ruins of the fort exist. For the ancient history of Esdraelon consult the Old Testament; many of the important places mentioned in the New Testament are in a good state of preservation. Nazareth, Nain, and all the surrounding section west of Mount Tabor, are usually included in the plain, and must be so considered if Mount Tabor is accepted as on the northeast boundary. Consult: Thomas, 'Two Years in Palestine'; Sayce, 'Patriarchal Palestine'; Costello, 'The Gospel Story'; Smith, 'Historical Geography of the Holy Land.'

Es'dras, Books of, two apocryphal books, which, in the Vulgate and other editions, are incorporated with the canonical books of Scripture. In the Vulgate the canonical books of Ezra and Nehemiah are called the first and second, and the apocryphal books the third and fourth books of Esdras. The Geneva Bible (1560) first adopted the present nomenclature, calling the two apocryphal books first and second Esdras. The subject of the first book of Esdras is the same as that of Ezra and Nehemiah, and in general it appears to be copied from the canonical Scriptures. The second book of Esdras is supposed to have been either of much later date, or to have been interpolated by Christian writers. This book takes its name from the supposed writer, a priest and doctor of the law, called Ezra by the Hebrews.

Es'erin, or **Physostigmin,** a drug obtained from Calabar-bean, the active principle of this plant, used as a remedy in cases of tetanus (lockjaw). A solution of eserin dropped in the eye causes contraction of the pupil, and hence its use in some eye ailments, as, for instance, glaucoma.

Esh'er, Reginald Baliol Brett, 2D VISCOUNT, English writer: b. London 30 June 1852. He was educated at Eton and Cambridge, and was private secretary to the Marquis of Hartington, then leader of the Liberal party, 1878–85. He was member of Parliament for Falmouth 1880–5, and in 1895 was appointed secretary to H. M. Office of Works, a post he retained until 1902. He succeeded his father as viscount in 1899. He has written: 'Footprints of Statesmen' (1892); 'The Yoke of Empire'; and many historical and political articles in the 'Fortnightly Review' and 'Nineteenth Century.'

Esh'er, England, village in Surrey, 15 miles southwest of London. Claremont Palace, where the Princess Charlotte resided and died, is in the neighborhood. Pop. 2,516.

Esk (Celtic for water), the name of two small rivers in England, one in Cumberland and one in Yorkshire; and of several in Scotland, the chief being the Esk in Dumfriesshire; the North Esk and South Esk in Forfarshire; and the North Esk and South Esk in Edinburghshire.

Es'kers, Eskars, or **Eschars,** deposits of gravel and sand evidently caused by the drift beneath the ice sheets of the Glacial periods. Such deposits are found in the northern part of North America, in Ireland where they are called escarks; in Scotland where they are known as kaims or kames; in Sweden as ösars. They sometimes consist of long ridges of sand and gravel, 40 and 50 feet high, and again are in large triangular masses, as in Sweden where the forms are very irregular. See GLACIER; GLACIAL PERIOD.

Eski-Sagra, ĕs'kĭ-sä'grä, or **Ezki Zaghra,** Rumelia, a town in the eastern part, on the south slope of the Balkans, about 100 miles northwest of Adrianople. It is near the chief passes of the Balkan Mountains, and its trade is increased because of its location. The mineral springs and extensive rose gardens nearby are sources of wealth for the town. Some of the manufactures are carpets, coarse linen, leather, and rose oil. It is one of the South Balkan strongholds which repelled the Russians in 1887. Pop. (1902) 19,521.

Eski-Shehr, ĕs'kĭ-shĕhr' (ancient DORYLÆUM), Turkey, a town 90 miles southeast of the Sea of Marmora. It has warm mineral springs, and manufactures of meerschaum pipes from the deposits of meerschaum in the neighborhood. The region of Asia Minor surrounding Eski-Shehr is noted for the quantity and quality of the meerschaum deposit. About two thirds of the people are Mohammedans and the remainder are Christians. Pop. 19,615.

Eskilstuna, ĕsk'il-stoo-nä, Sweden, city on the river of Eskilstuna, connecting Lake Maelar with Lake Hjelmar. It has daily communication with Stockholm, both by steamers and rail. On an island in the river is a large gun-factory, and its manufactures of iron and steel products are so great that it is called the "Sheffield of Sweden." The place takes its name from Saint Eskill, an English missionary of the 11th century, who, it is said, was martyred at a pagan assembly held where the city of Eskilstuna now stands.

Es'kimo Dog, the draft animal of the Arctic regions. It is a wolfish-looking dog, largely or sometimes wholly derived from the wolf, tinged with yellow or with a grayish color, having an outer coat of long hair, and an undercoat of soft wool. Its short pricked ears and bushy tail add to its wolf-like appearance. Its cry is not a bark, but a long melancholy wail. This dog is trained to hunt the polar bear and to drag the Eskimo's burdens over the rough ice, when harnessed in "trains" to sledges, and is highly prized in the frozen North.

Eskimos, or **Esquimaux,** es'ki-mō, the name of the inhabitants of the northern coast of the American continent down to lat. 60° N. on the west, and 55° on the east, and of the Arctic islands, Greenland, and about 400 miles of the nearest Asiatic coast. They have been met with as far as Arctic discoverers have hitherto advanced toward the pole. They prefer the vicinity of the seashore, from which they rarely withdraw more than 20, and hardly ever 80 miles. Their number scarcely amounts to 40,000. Nevertheless they are scattered as the sole native occupants of regions stretching 3,200 miles in a straight line east and west, to travel between the extreme points of which would necessitate a journey of no less than 5,000 miles. This distance, taken in connection with their homogeneous nature and manners, makes their small bands the most thinly scattered people of the globe. Their extraordinary persistency in maintaining their language and habits must be due to the difficulties they have had to face in procuring subsistence where no other nation can live. They call themselves ***Innuit*** ("the people").

Race.— They used to be classed among nations of the Mongolian stock; but now they are considered as akin to the American Indians. Their height nearly equals the average of the Indians. They appear comparatively taller sitting than standing. Their hands and feet are small, their faces oval, but rather broad in the lower part; their skin is only slightly brown; they have coarse black hair and very little beard. The skull is high.

Habits.— The Eskimos get their subsistence mostly from hunting by sea, using for this purpose skin boats where the sea is open, and dog sledges on the ice. From the skin, blubber, and flesh of the seal and the cetaceous animals, they procure clothes, fuel, light, and food. Their most interesting as well as important invention for hunting is the well-known small skin boat for one man, called a kayak. It is formed of a framework covered with skin, and, together with his waterproof jacket, it completely protects the man against the waves, so that he is able to rise unhurt by means of his paddle, even should he capsize. In winter the Eskimos are undoubtedly stationary. But during the summer, when sufficient open water is found, they roam about in their large skin boats. Their winter dwellings vary with regard to the materials of which they are built, as well as in their form. In the farthest west they are constructed mostly of planks, covered only with a layer of turf or sod; in Greenland the walls consist of stones and sod; in the central regions the houses are formed merely out of snow. In Alaska the interior is a square room, surrounded by the sleeping places, with the entrance on one side, while a hearth with wood as fuel occupies the middle of the floor. The number of inhabitants at an Eskimo station or village is generally under 40, but in rare cases more than 200 are found. A funnel-shaped, half-underground passage forms the entrance of the narrow dwellings.

Dress.— The dress of the Eskimos is almost the same for the women as for the men, consisting of trousers or breeches and a tunic or coat fitting close to the body, and covering also the head by a prolongation that forms the hood. For women with children to carry, this hood is widened so as to make it an excellent cradle, the amaut. Tattooing has been general among all the tribes. The ordinary materials of which clothes are made are the skins of seals, land animals, and birds.

Language.— The language is characterized by the power of expressing in one word a whole sentence in which are embodied a number of ideas which in other languages require separate words. The Greenland dictionary contains 1,370 radicals and about 200 affixes. A radical may be made the foundation of thousands of derivatives, and a word can be composed which expresses with perfect distinctness what in our civilized languages might require 20 words. In Greenland and Labrador the missionaries have adapted the Roman letters for reducing the native language to writing. The printed Greenland literature, including what has been published by the Moravian Brethren, amounts, with pamphlets and the like, to what might make 70 to 80 ordinary volumes.

Sociology.— It is doubtful whether an organization like that of the Indian "families" has been discovered among the Eskimos. But a division into tribes, each with their separate territories, actually exists. The tribe again is divided into groups constituting the inhabitants of the different wintering places. Finally, in the same station, the inhabitants of the same house are closely united with regard to common housekeeping.

Religion.— The inhabitants of Danish West Greenland, numbering about 10,000, the greater part of the Labradorians, and the southern Alaska Eskimos are Christianized. As for the rest, the religion of the Eskimos is what is generally designated as Shamanism.

The name Eskimo is said to be formed by corruption out of an Indian word signifying "eaters of raw meat." Their origin generally has been derived from Asia, but now they are believed by some to have come from the interior of America, and, following the river courses, to have arrived at the Arctic sea, where they have developed their abilities as an Arctic coast people. The Eskimos may be divided into the following groups: (1) The Western Eskimos, inhabiting the Alaska territory and the Asiatic side of Bering Strait; (2) the Mackenzie Eskimos, or Tchiglits, from Barter Island to Cape Bathurst; (3) the inhabitants of the central regions, including the Arctic Archipelago; (4) the Labradorians; (5) the Greenlanders. A side branch inhabits the Aleutian Islands.

The Christianized natives still preserve their ancient folklore. It represents at the same time their original poetry, religious ideas, and history, praising the deeds of their great men in braving the dangers to which their race has been continually subjected. The 'Tales and Traditions of the Eskimo' (1875) comprise a collection of 150 tales founded on versions supplied by about 50 narrators from different parts of Greenland, and a few from Labrador. A valuable collection has since been acquired from East Greenland, some tales from Baffin Land, and a number of the simplest fragments of the same from Bering Strait. See ALASKA; ARCTIC EXPLORATION; ETHNOLOGY; GREENLAND; LABRADOR.

Bibliography.— McLean, 'Notes on the Hudson Bay Territory' (1846); Hall, 'Life with the Eskimos' (1864); Rink, 'The Eskimo Tribes' (1887); Pilling, 'Bibliography of the Eskimo Language' (1888); Peary, 'My Arctic Journal' (1893); Nansen, 'Eskimo Life' (1894).

Es'ler, Erminda Rentoul, Irish novelist: b. Ireland. She married Robert Esler, M.D., in 1883. She has published: 'The Way of Transgression' (1890); 'The Way They Loved at Grimpat' (1894); 'A Maid of the Manse' (1895); 'Mid Green Pastures' (1895); 'The Wardlaws' (1896); 'Youth at the Prow' (1898); 'The Awakening of Helena Thorpe' (1901).

Esmann, ĕs'män, **Gustav Frederik,** Danish dramatist: b. Copenhagen 17 Aug. 1860. After a short period of legal study, he abandoned law for literature, and his first work was a volume containing two short stories, 'Gammel Gjaeld' (1885). Thereafter he devoted himself mainly to dramatic composition, and a notable series of plays, which have been acted with great success throughout the Scandinavian countries, have come from his pen. They are: 'I Stiftelsen' (1886); 'Enkemænd'; 'Før Bryllupet'; 'I Provinsen' (1890); 'Den Kære Familie' (1892); 'Magdalene' (1893); 'Den Store Maskerade'

(1895); 'Vaudrefalken' (1898); 'Det Gamle Hjem' (1899); 'Sangerinden' (1901).

Esmarch, Johannes Friedrich August, yō-hän'nĕs frēd'rĭh ow'goost ĕs'marh, German military surgeon: b. Tönning, Schleswig-Holstein, 9 Jan. 1823. He received his medical and surgical education in the universities of Kiel and Göttingen, and in 1860 was appointed professor and director of the Kiel Hospital. In 1870 he was a member of the hospital commission of the Prussian army and introduced a system of bloodless operations. In the autumn of 1888 he made a trip to the United States. He was an authority especially on gunshot wounds.

Esmeraldas, ĕs-mā-räl'däs, Ecuador, a province, etc. See ECUADOR.

Esneh, ĕs'nĕ, or **Esne,** a province in upper Egypt, situated on both banks of the Nile. The town of the same name, which is the capital of the province, stands about 30 miles above Thebes on the left bank of the river. It is a seat of manufactures, and produces blue cotton cloth and pottery, and is a depot of caravans from Abyssinia and Sennaar. The town was anciently called Latopolis; and was the centre of worship of the fish latus, a species of carp. Among the ruins of this once populous city is the temple, whose portico is in good preservation, having 24 beautiful columns, and a zodiac on the ceiling. Pop. 12,000.

Esocidæ, ĕ-sŏs'ĭ-dē. See LUCIDÆ.

E'sopus War, a long-continued and desultory conflict between the Dutch and the Indians at a place in Ulster County, N. Y., known to the Indians as Esopus, but now called Kingston. This series of skirmishes began in 1658, when the Dutch fired upon some Indian farm hands, who were drunk and riotous. Esopus, which the Dutch called Wiltwyck, was at last destroyed by the aborigines, who carried off 40 women and children, and killed 21 men. Gov. Stuyvesant sent out a strong force to punish the Indians, and in May 1664 a treaty of friendship was ratified.

Esoteric, ĕs-ō-tĕr'ĭk (Gr. *esōterikos*, "inner"), a term used in opposition to exoteric. In reference to the teaching of Pythagoras, Aristotle, and other ancient philosophers, it refers to those doctrines which they expounded to their select disciples, in contradistinction to those which they published to all the world (exoteric). The distinction does not necessarily imply that the esoteric doctrines were kept secret as a mystery, but only that they were of a higher and more difficult order. See ARISTOTLE; PYTHAGORAS.

Espalier, ĕs-păl'yėr, in gardening, a sort of trellis-work on which the branches of fruit-trees or bushes are extended horizontally, with the object of securing for the plant a freer circulation of air as well as a full exposure to the sun. Trees thus trained are not subjected to such marked nor so rapid variations of temperature as wall-trees. The term is most commonly used in France, where it is applied to a row of trees planted along a wall. See TRELLIS.

Espartero, Baldomero, băl'dō-mā'rō ĕs-pär-tā'rō, DUKE OF VITTORIA, Spanish statesman: b. Granatula 27 Feb. 1792; d. Logrono 9 Jan. 1879. The son of a wheelwright, he was educated for the priesthood, but joined the army as a volunteer in 1808. He took a leading part in the conflict with the Carlists, and was one of the most prominent men in Spain during several decades of the 19th century. He was regent of the kingdom in 1841–3, and again head of the government in 1854–6. In 1868 his name was put forward in the Cortes as a candidate for the throne, but the proposal was unsuccessful and the closing years of his life were spent in retirement.

Espar'to (Gr. *spartos;* Lat. *spartum*), a grass, the *Stipa* or *Macrochloa tenacissima*, growing native in Spain and Africa, known to the ancients, and applied by them to the manufacture of cordage, matting, etc., and still more extensively used at the present day. A few species of *Stipa* are found in dry woods from New England, south to Wisconsin. Esparto grows in tufts and bunches, like rushes, to a height of from two to four feet, and has a long, flat, lanceolated blade, which becomes cylindrical when the ripened plant begins to dry. It is pulled up by the roots, dried in the sun, and packed in bundles for exportation. Besides the various uses already indicated, esparto has for some time been applied to the manufacture of paper. Formerly the supply of esparto was almost wholly obtained from Spain, but a closely allied fibre called alfa (*Macrochloa arenaria*) is now obtained in still larger quantity from Algeria, while a third fibre, dis (*Festuca patula*), is imported for the same purpose from Tripoli and Tunis. See FEATHER BUNCH-GRASS; FIBRE.

Esperanto Language. "Esperanto," successor to "Volupuk" in the effort to establish an international language, has made considerable progress. The latest reports, which include a statement of events at the Congress of Esperantists held at Boulogne from 5–13 Aug. 1905, show that a substantial and probably lasting interest in this latest linguistic enterprise now exists in several of the larger European countries.

In 1887 Dr. Zamenhof, a Russian physician, issued his first pamphlet concerning a suggested new international language to be called "Esperanto." Only trifling progress was made during the first ten years of the movement. The idea first took root in the originator's native country. Russian educators and other men of culture looked upon the innovation with favor. After the lapse of a decade, a start was made to introduce the Zamenhof idea among the Norwegians and Swedes. They, too, showed a friendly attitude. Then France became interested, and the famous linguist, M. de Beaufront, who had himself previously devised a plan along similar lines, threw his own scheme aside and accepted that of Dr. Zamenhof as being better fitted for the purpose intended. The result of this vigorous and decisive movement in France by so distinguished a man as M. de Beaufront was that France almost immediately became prominent as a stronghold of Esperantism.

From France the movement extended to Germany, thence to Austria, Switzerland, Italy and England. In the latter country 30 societies of Esperantists were organized within a year of the system's introduction. During the past few months, active missionary work has been undertaken in the United States, looking toward the promulgation of the Zamenhof plan for use in commercial, educational and other fields. There is little doubt as to the success of the outcome, indorsed as it is by some of the greatest philologists in Germany, Austria, England and France.

Advocates of an international language have in the past, included numerous philosophers and scientists, including Roger Bacon, Descartes, Pascal, Leibnitz, Locke, Condillac, Voltaire, and Diderot. Only of late years have the linguistic theories of these famous thinkers been moulded into anything like practical shape.

Occasions Calling for the Use of an International Language.— One of the principal reasons for renewal of interest in the direction of one universal language is the necessity for producing a vehicle of common expression among delegates representing various countries at congresses and on similar occasions. It has been found difficult for individuals, acting for their respective nations, to keep in touch with the proceedings from day to day. The extended use of Esperanto and the widespread appreciation manifested in its development indicate that the method of Dr. Zamenhof offers a feasible solution of what has, hitherto, been an unsolved problem.

In addition to the advantages of having a common language for cosmopolitan assemblages, the transaction of voluminous mercantile affairs between nations and merchants of various nations require some such system to facilitate the making of purchases and adjustment of mercantile accounts.

For educational purposes, as in other ways, the availability of a means whereby educators can compare systems and processes without encountering the difficulties connected with proper and complete translation is very evident.

Present Uses of the Esperanto Language.— From a recently-published review it is learned that books on the Esperanto language are now being printed in more than twenty languages. The number of periodicals, including those strictly scientific, printed in the Esperanto language, is estimated at twenty-five. On the continent of Europe, representative daily and weekly newspapers, occasionally or regularly, publish articles in Esperanto. Esperantist clubs and societies are operating in many European cities and have large membership. Among the most important are those of Paris, with 3,000 members, Marseilles, Lyons, Bordeaux, Havre and Lille.

Several French publishers have undertaken, in an extensive way, to publish Esperanto works, conditional on the possession of exclusive rights. Quite a number of large commercial concerns are using the system for cable and telegraphic purposes. Courses of study in Esperanto form an attractive feature in commercial schools, clubs and public institutions, some of which make a special feature of teaching the blind to read by the new system. An Esperanto typewriting machine is one of the latest developments, and in that connection many stenographers are learning the use of the language for shorthand purposes.

In the colleges and schools, Esperanto is commanding considerable attention. One of the greatest Esperantist triumphs was the recent delivery of an address in the Esperanto language by Mr. Moch, the famous peace advocate, at the International Peace Congress, Luzerne. At the Boulogne congress, 1,200 delegates from 22 countries spoke the Esperanto language freely and understood each other thoroughly. A complete test was made by means of speeches, discussions, concerts, dramatic performances and religious services.

During the congress, the work of Dr. Zamenhof was officially noticed by the French government. The Minister of Public Instruction extended thanks in behalf of the President of the Republic and of the people of France. In the course of the proceedings a reception was tendered to the creator of Esperanto at the Hotel de Ville, Paris.

Method of the Esperanto Language.— In the general plan of Dr. Zamenhof the aim is to omit all accidental words in the language of each nation, retaining only such words as are common to all nations. Sounds peculiar to any one language are eliminated. The English *th* and *w*, appearing in English words, but not in those of the French or German languages, are, therefore, according to the rule of the originator of Esperanto, dropped. The French *u*, the German *u*, and the French nasals, not used in English, are left out, also the Spanish *n* and *j*, and the German *th*. The pursuance of this plan removes all difficulties as to pronunciation.

Phonetic spelling is the Esperanto rule, a certain letter having the same sound always. Mute and double letters are cut out. The letter *x* becomes *ks*, *ph* becomes *f*, *ch* becomes *k* for the guttural sound, and *ĉ*, *c* remaining for the ordinary sound in words like cigar. The g is used only for the guttural (gril, garb), and *ĝ* is used for the sibilant *aĝ* which is equal to *age*. New signs introduced are *ĉ* and *ĝ*. But these are for sounds already recognized. A third sign takes the place of a double letter, viz., *ŝ* for *sh* (*ŝip* equals ship and *ŝi* equals she). Further details regarding the vocabulary, prefixes and suffixes — in fact, the whole grammar — have been issued in separate form and can be readily obtained by students. It will suffice to say here that the Esperanto vocabulary is much smaller than that of any other language, being only about 2,000 words, exclusive of scientific and technical words, as compared with 32,000 in the French language, a considerably larger number in the German language, and over 100,000 in English. The simplicity of the Esperanto grammar is quite remarkable. The majority of those who undertake the study of Esperanto, diligently, under proper instruction, master it in a short time. See UNIVERSAL LANGUAGE; SCIENCE OF LANGUAGE; etc.

Espinas, Alfred Victor, äl-frā vēk-tōr ā-spē-nä, French sociologist: b. St. Florentin, Yonne, France, 23 May 1844. After teaching philosophy in the lycées of Bastia, Chaumont, Havre, and Dijon, he became successively professor of philosophy in the universities of Douai, Lille, and Bordeaux, and in the latter was dean of the faculty of letters 1887–90. Since 1894 he has been professor of the history of social economy, on the Chambrun foundation, in the faculty of letters of the University of Paris. Besides contributing largely to the 'Revue Philosophique,' he has translated (with Ribot) Herbert Spencer's 'Psychology' (1874), and written: 'Des Sociétés Animales' (1877–8); 'La Philosophie Expérimentale en Italie' (1880); 'Histoire des Doctrines Economiques' (1893); 'Les Origines de la Technologie' (1897); 'La Philosophie Sociale du XVIIIe Siècle et la Révolution' (1898).

Espirito-Santo, ĕs-pē'rē too-sän'tō, Brazil, a state bounded on the north by the state of Bahia, on the east by the Atlantic Ocean, on the south and west by the states of Rio de Janeiro and Minas Geraes. Area 17,307 square miles. Near the capital, Victoria, and the former capital, Villa Velha, are the small mountains Penha, Moreno, Frade Leonardo, and Mestre Alvares: the highest of these, Mestre Alvares, is one of the most conspicuous landmarks on the Brazilian coast. The state has immense forests, and is noted for the valuable woods found in them. The Doce River flows through some of the richest of the hinterlands, but is navigable only for very small craft. São Matheus, in the northern part of the state, is surrounded by coffee and mandioca plantations, the products of which are shipped from this port, officially known as Conceição da Barra. A number of small ports intervene between the Doce River and the spacious bay of Espirito-Santo, which has given its name to the state. Coffee, the chief agricultural product, is largely exported. Other exports are: tapioca, mandioca, cotton, cacao, hides and skins, and woods. A railway is being built to connect Ouro Preto, on the upper waters of the Doce, with the coast. Cotton goods are manufactured in the town of Pessanha. The population of the state, which was 135,997 in 1890, has increased to 382,137, this growth being due to European immigration. A few years ago the city of Victoria (pop. 8,000 in 1890, but 20,000 in 1901) had almost no maritime trade, as its port was too shallow to admit large vessels. Recently improvements have been made in the harbor, which now accommodates transatlantic steamers, and both trade and immigrants have sought it. Colonies of Germans, Poles, Swedes, Tyrolese, Portuguese, and Italians are established near Anchieta, Alfredo Chaves, Itapemirim, and Cachoeiro — chiefly in the southern part of the state. Some of these colonies are under government protection, receiving annual subsidies of seeds and cattle, but the majority of the colonists already own lands which they work without government aid.

Esplanade, ĕs-plā-nād', in fortification, the wide open space left between a citadel and the nearest houses of the city, to prevent an enemy from being able to assail it under cover of these houses. The term is also frequently applied to a kind of terrace, especially along the seaside, for public walks or drives.

Espou'sal (Sponsalia), or **Betrothal,** in the Roman Catholic Church consists of a deliberate mutual promise of marriage, expressed by outward signs, between two persons, both of whom may lawfully and validly enter into such an engagement. When such promise is made and accepted on both sides, neither party can lawfully withdraw from it without the other's consent or unless something occurs or some circumstance comes to light which, had it been known in time, would have hindered the engagement. Formerly such engagements used to be made with some solemnity *coram ecclesia* or at least in presence of witnesses; now they are usually made without ceremony or publicity.

Espronceda, José de, hō-sā' dā ĕs-prōn-thā'dä, Spanish poet: b. Almendralejo in Estremadura 1810; d. 23 May 1842. A precocious poet and revolutionist, he wrote the epic fragment 'Palayo' in confinement, and was repeatedly exiled. His most notable poems are: 'The Pirate'; 'The Beggar,' preaching socialism; 'The Headsman'; the grewsome 'Student of Salamanca'; 'The Clean Demon' (1841). The volume 'Forgotten Pages' was issued in 1874.

Es'py, James Pollard, American meteorologist: b. Washington County, Pa., 9 May 1785; d. Cincinnati 24 Jan. 1860. He was graduated at Transylvania University 1808. The name "storm-king" was given to him for his originating a theory of storms which involved him in much controversy. This he embodied systematically in his 'Philosophy of Storms' (1841). His meteorological doctrine on the point of how atmospheric disturbances commence was approved by the French Academy, but his views as to the mechanics of storm are contrary to received fact, and have been exploded. His principal contribution to practical meteorology was his institution of a system of telegraphic weather bulletins, which should converge at the capital and give daily intelligence of the weather in different widely separated points, and it may be justly claimed that he thus laid the foundation of all sound theory on the subject of weather prediction.

Esquimalt, ĕs-kwī'mält, Canada, seaport in British Columbia, on the southeast coast of Vancouver Island, and on the Strait of San Juan de Fuca; four miles from Victoria. The harbor is extensive and capable of receiving vessels of the greatest size, and is the British naval station for this part of the Pacific coast. It has a navy yard, marine hospital, a large dry dock built by the Dominion government in 1888, and a meteorological station. In 1894 the British government started work on the defenses of Esquimalt, consisting of earthworks, with disappearing guns, and two parapet forts on the hills for protection against a possible attack by land. The harbors of both Esquimalt and Victoria are kept thoroughly mined and wired, and constitute one of the best defended naval stations in the world. The population, exclusive of the British soldiers, officials and some of their families, is small, estimated in 1903, 2,000.

Esquimaux. See Eskimos.

Esquire, originally, a shield-bearer or armor-bearer, an attendant on a knight; hence, in modern times a title of dignity next in degree below a knight. In Great Britain this title is given properly to the younger sons of noblemen, to officers of the king's courts, and of the household, to counselors at law, justices of the peace while in commission, sheriffs, gentlemen who have held commissions in the army and navy, and in fact to anyone save tradesmen, mechanics, and peasants. It is usually given to all professional and literary men, both there and in the United States. In heraldry the helmet of an esquire is represented sideways with the visor closed.

Esquirol, Jean Etienne Dominique, zhŏṅ ā-tē-ĕn dō-mē-nēk ĕs-kē-rŏl, French physician: b. Toulouse 4 Jan. 1772; d. 12 Dec. 1840. His life was chiefly given to improving the methods of treating the insane, and he contributed greatly toward the abolition of the barbarous methods so long in vogue. In 1799 he founded a model asylum at Paris; visited all the asylums in France 1808; was appointed physician to the Saltpêtrière 1811; and in 1826 became head of the private asylum at Charenton, which he had largely planned. In 1817 his public revelations of the abuses current in French asylums led the government to appoint an investigating commission. His studies included the architecture and construction of asylums, and the best of the earlier 19th century buildings for the insane in France, such as those at Rouen, Nantes, and Montpellier, were built in accordance with his plans and instructions. He wrote: 'Des Illusions chez les Aliénes' (1832; Eng. tr. 1833); 'Des Maladies Mentales' (1838); and articles in 'Dictionnaire des Sciences Médicales,' and 'Encyclopédie des Gens du Monde.'

Esquiros, Henri François Alphonse, ŏṅ-rē fräṅ-swä äl-fōns ĕs-kē-rōs, French poet and miscellaneous writer: b. Paris 23 May 1814; d. Versailles 12 May 1876. His first work, a volume of poetry, 'Les Hirondelles,' appeared in 1834. This was followed by numerous romances, and a socialistic commentary on the life of Christ; 'L'Evangile du Peuple' (1840), for which he was prosecuted and imprisoned. He then published: 'Les Chants d'un Prisonnier' (1841), poems written in prison; 'Les Vierges Folles' (1842); 'Les Vierges Sages' (1842); 'L'Histoire des Montagnards' (1847); etc. Having to leave France in 1851, he resided for years in England, and wrote a series of essays for the 'Revue des Deux Mondes' on English life and character, which were translated under the title of 'The English at Home,' and were very popular. He also wrote a similar work on the Dutch. Other works of his are: 'Le Droit au Travail' (1849); 'Histoire des Martyrs de la Liberté' (1851); 'La Morale Universelle' (1859); 'Les Paysans' (1877); 'Le Château Enchanté' (1877), a novel.

Esquivel, Juan de, hoo-än' dā ĕs-kē-vĕl, Spanish soldier: b. 1470; d. 1519. He was the companion of Ovando when the latter went to Hispaniola to succeed Bobadilla as governor. In 1509 he conquered the island of Jamaica and settled it as a Spanish possession. The colony flourished under his administration, and he founded there the city of Sevilla Nueva.

Ess, Johann Heinrich van, yō-hän hīn'rĭн fän ĕs (better known by his Benedictine name «Leander»), German theologian: b. Warburg 15 Feb. 1772; d. Affolderbach in the Odenwald 13 Oct. 1847. He entered the Benedictine abbey of Marienmuster as a novice 1790; was pastor at Schwalenberg 1799–1812; and professor of theology at the seminary in Marburg 1812-22. In 1807, with his cousin Karl, he published a German translation of the New Testament, the circulation of which was forbidden by the Pope. The following year he published a defense of his views as to Bible reading by the people, a new edition of which was issued in 1816 entitled 'Gedanken über Bibel und Bibellehre.' After 1822 he gave his whole time to circulating his Bible versions among the people, to spreading his doctrines, and to the composition of a German version of the entire Scriptures, which he finished in 1840. Others of his publications are: 'Was War die Bibel den Ersten Christen?' (1816); 'Die Bibel Nicht ein Buch für Priester' (1818); an edition of the Vulgate (Tübingen 1822–4); of the Septuagint (1824; new ed. 1887); and of the Greek New Testament (1827).

Essay, a composition in which something is attempted to be briefly proved or illustrated. It is not easy to define the limits of the essay as a species of composition. In general it is understood of the briefer and less elaborate efforts of literary skill; but this distinction is not always maintained. Caution or modesty has induced many writers of note to give the title of essay to their most elaborate productions; thus we have Locke's 'Essay on the Human Understanding.' The subject of an essay may be any topic of human interest; it may be philosophical, scientific, logical, ethical, æsthetical, or humorous; and a series of essays may embrace connected, but so far independent views of the most extensive range of subjects. There is a class of English writers to whom the descriptive term essayist is applied. 'The Spectator,' 'The Tatler,' 'The Rambler,' and many other extensive collections, are among the works of this class of writers, the best of whom, from the variety which their works present in other particulars, can only be distinguished by excellence of style. In the United States Emerson is the most favorably known among essayists. From the brevity of the essay, considered in its ordinary sense, and the necessity of giving it some specific claim on the attention of cultivated readers, style may possibly be considered to have been, at least until recently, the distinctive characteristic of essay writers, and this form of composition may be supposed to have done some service in maintaining the standard of purity and excellence in the English language. See English Literature.

Essay on Criticism, An, a didactic poem by Pope (1711) in which he brilliantly explained and propounded the canons of verse structure and poetic taste. The poem abounds in striking passages which have become familiar quotations. See Pope, Alexander.

Essay on Man, An, a famous philosophical poem by Alexander Pope (q.v.), which appeared in four parts, 1732 to 1734. It was imitated by Voltaire and others. It contains many expressions which have become proverbial.

Essay on the Human Understanding, a famous philosophical work by John Locke (q.v.) (1690).

Es'sen, Germany, town of Rhenish Prussia, 18 miles northeast of Düsseldorf. It has recently greatly increased in population and manufactories. It is celebrated for the steel and iron works of the Krupps, the most extensive in Europe, employing about 28,000 workmen. This great establishment was started in 1827, with only two workmen. The rifled steel cannon made here are supplied to most of the armies of Europe. In the suburbs are the «colonies» — cottages, churches, schools, stores, libraries, places of amusement, homes for superannuated and disabled workmen, etc., established by the Krupps for their workmen. The town was founded in the 9th century, when the Benedictine abbey was established here, and for some time it was under the control of the Abbess of Essen. In the 10th century the Abbess Hagona gave the town municipal privileges. Pop. (1900) 118,863.

Essence, in metaphysics, originally the same as substance. Later, substance came to be used for the undetermined substratum of a thing, essence for the qualities expressed in the definition of a thing; or, as Locke put it, "Essence may be taken for the very being of a thing, whereby it is what it is." In chemistry, and in popular parlance, essences are solutions of the essential oils in alcohol, and may be prepared by adding rectified spirit to the odoriferous parts of plants, or to the essential oils, and distilling; or simply by adding the essential oil to the rectified spirit, and agitating till a uniform mixture is obtained. The term has, however, received a wider significance, and is applied to any liquid possessing the properties of the substance of which it professes to be the essence. Thus essences of coffee and beef, and rennet contain in a concentrated form the virtues of coffee, and beef, and in some circumstances may be substituted for them.

Essenes, ĕs-sēnz' (Εσσηνοι, Εσσαιοι, *Esseni*), a sect or society of Hyper-Pharisaic Jews which was already in existence 150 years B.C., and which existed till the 4th century; the remnant then returning to Pharisaic or orthodox Judaism or entering the Christian communion. Josephus the historian (1st century) describes their manner of life in some detail; Philo Judaeus has a notice of it, so too has Pliny in his 'Historia Naturalis.' Josephus was in his youth a probationer of the society, but lived among them only a short time and was unacquainted with the details of their system, which were strictly withheld from novices; but his narrative has the marks of authenticity. In essentials Josephus and Philo are in accord, and with them agrees Pliny in the one peculiarity of this society which he notices — their celibate life. The Essenes were stern ascetics and in that respect were the prototype of the Christian Solitaries, who in the 3d and 4th centuries peopled the Nubian deserts: withal, they were both in name and in deed Friends — for such was one of the appellations of the brethren. Among themselves they had all things in common, like the first Christians, and they were open-handed and hospitable to strangers. There were groups of Essenes in all the towns of Judea, but their institute had opportunity for full development only in their communal settlements on the western shore of the Dead Sea, where they devoted themselves to their peculiar religious observances and to agriculture and a few simple handicrafts. Their food was of the simplest, taken at the common board, their only drink, water; their attire was of the plainest, white linen material. None possessed more than one tunic or more than one pair of shoes. They rose at daybreak for prayer; after prayer and a hymn they went about their customary occupations. (Here we are reminded of what Pliny wrote to Hadrian concerning usages of the Christians in Bithynia: "They met on a stated day before daybreak and chanted a hymn to Christ as God.") At the 5th hour (11 A.M.) they again assembled in one place and bathed their faces in cold water, after which they put on pure white garments and repaired to the common simple meal, which was preceded by a blessing, a prayer and a hymn; and after the repast there was again prayer and a hymn. Then the brethren put off the ceremonial garb of white linen, put on their workday attire, and went back to their employments. No women were admitted to the order; like some of the modern Shakers they adopted young boys and brought them up in their own simple way of living; on attaining maturity they might, if willing, be admitted to membership after a term of probation; or they were free to return to the world. But they also received accessions of life-weary grown people. "Thus," says Pliny, "here is a people that never dies out (*æterna est*) yet in which there are no births: so fruitful for them is others' 'disgust of life'" (*Tam foecunda illis aliorum vitæ pœnitentia est*). Like the Society of Friends they forbade oaths; and they held that a man whose word needed to be confirmed by oath was not to be believed at all. Nevertheless the postulant for admission into the society was required to take "terrible oaths" that he would pay worship to God, be just to men, injure none, hate the unjust, be faithful and true to all, especially rulers, for none bears rule save by God's will. Pliny writes of a similar oath taken by the Christians.

There were four degrees of membership resembling in some respects the castes of the Hindus. If a person in a higher degree so much as touched one of a lower grade, he was thereby defiled and was bound to make himself clean in cold water. Their severely abstemious life, their contempt for riches and honors, their deep conviction of the immense superiority of their religion gave them all the heroic courage in face of persecution and torture which distinguished the Christians in the ages of martyrdom. So scrupulous were they in avoiding everything like idolatry, that some of them would never enter any city because of the images erected at the gates; nor would they touch a coin that bore the likeness of any ruler.

Consult: Pliny, 'Historia Naturalis'; the writings of Josephus and Philo Judacus; also *Philosophumena*, or 'Refutation of all Heresies,' written in Greek 230 A.D., author unknown.

Essential Oils. See OILS.

Essequibo, ĕs-sĕ-kē'bō, a river of British Guiana, which flows into the Atlantic by an estuary 20 miles in width. Its course is very irregular; its whole length is about 600 miles. It is navigable for some distance from the ocean. The district or division of Essequibo, which is in the basin of the Essequibo River, is well cultivated and extremely fertile, producing coffee, cotton, cocoa, and sugar. A portion of the basin of this river was included in the disputed territory claimed by the Venezuelan and the British governments in 1896. The claims were settled by treaty 2 Feb. 1897. Pop. 36,000.

Essex, Robert Devereux, 2D EARL OF, English courtier: b. Netherwood, Herefordshire, 10 Nov. 1567; d. London 26 Feb. 1601. He was educated at Trinity College, Cambridge, and appeared at court in 1577. On Leicester's death 1588, he became the chief favorite of Elizabeth. In 1590 he married the widow of Sir Philip Sidney, and in 1591 was sent to support Henry IV. against Spain, but the expedition effected nothing of importance. About this time Essex was on terms of close friendship with Francis Bacon, who assisted him greatly by advice on political and other matters. In 1596 he commanded an expedition to Spain, and greatly distinguished himself at the capture of Cadiz.

In 1597, after an unsuccessful expedition to the Azores, he, with Howard and Raleigh, made extensive captures of Spanish ships. Next year he quarreled with the queen, who struck him on the ear and bade him "go and be hanged." After some months a reconciliation took place, and he was appointed lord-lieutenant of Ireland (1599), then in a state of rebellion. He returned to England in September, having been entirely unsuccessful in his government; was made a prisoner in his own house, and was shortly afterward (June 1600) tried by a special court. The charges against him were that he had exceeded his instructions in the Irish campaign, and had deserted his post without leave; and he was deprived of all his offices, and sentenced to imprisonment, but not long afterward was set at liberty. He now conceived a deep resentment against the queen's councilors, particularly Cecil and Raleigh, who, he imagined, had biased her against him. Being summoned before the council, he assembled his friends in his house, and proceeding to the city, endeavored to enlist the citizens in his favor. After a skirmish with a party of soldiers he returned to his house, but after a short defense was compelled to surrender, and sent to the Tower. He was tried for treason on 19 February, and executed on 26 Feb. 1601. See Spedding, 'Bacon' (1881); Abbott, 'Bacon and Essex' (1877).

Essex, Robert Devereux, 3D EARL OF, English soldier: b. 1591; d. 14 Sept. 1646. When 11 years old he was restored by James I. to the rank and titles held by his father, the 2d earl. He served in the army of the elector palatine in Holland 1620–3, was vice-admiral of an unsuccessful naval expedition against Cadiz in 1625, and lieutenant-general of an army sent by King Charles against the Scotch Covenanters in 1639. Espousing the cause of the Parliament against the king, he was appointed to the command of the parliamentary army at the beginning of the civil war, was victorious over Charles at Edgehill in 1642, captured Reading in 1643, and relieved Gloucester, but lost the greater part of his army in 1644. He urged the impeachment of Cromwell before the House of Lords in 1645, and had to resign his commission. An annuity of £10,000 was settled on him for life.

Essex, England, a maritime county, on the southeastern coast; area, 1,533 square miles, of which 80 per cent is under cultivation. The chief towns are Chelmsford, the county town; Colchester, Maldon, and Harwich. Pop. (1901) 1,085,576.

Essex, The, an American 32-gun frigate built 1799 for the war with France. She was used as a Pacific convoy, and served later in the wars with the Barbary pirates. In 1812 Capt. David Porter did effective work with her: cutting out a brig with 197 soldiers from a British transport fleet; forcing the 16-gun sloop Alert to strike in eight minutes; and in a cruise on the west coast of South America, capturing the entire British whaling fleet and other prizes, they and those destroyed aggregating $2,500,000 in value. In February 1814 two British vessels, the 36-gun Phœbe and the 18-gun Cherub, blockaded her in the neutral harbor of Valparaiso; on 28 March he attempted an escape, but the vessel was disabled by a sudden gale, and in a fight of 2 hours and 20 minutes was cut to pieces, losing 58 killed and 66 wounded out of 255, and being left in a sinking condition. The battle was a mere massacre: the British had 38 long guns to the Americans' 6.

Essex Junto, a name applied about 1781 by John Hancock to the group of Massachusetts political leaders resident in or connected with Essex County, Mass.— the northeastern county, from just north of Boston to the New Hampshire boundary. Its coast was a line of commercial and fishing towns, and its interests therefore overwhelmingly in favor of a strong national government to protect them from foreign countries and their sister States. This made its leaders, whose great ability gave them powerful influence, the vanguard of the ultra Federalists, and adherents of Hamilton, whom they followed in his split with John Adams. The latter revived the old nickname, charged them with being a "British faction" and forcing on a war with France, and for years after his retirement assailed them in the press. When the embargo (q.v.) and the later war solidified all New England Federalism in a common self-defense, all the opposition and the suspected treason were attributed by outsiders to the Essex Junto. Its chief members were George Cabot, Timothy Pickering, Theophilus Parsons (State chief justice), the Lowell family, Stephen Higginson, and Benjamin Goodhue.

Esslingen, ĕs'ling-ĕn, Germany, town in Würtemberg; on the Neckar, seven miles east-southeast of Stuttgart. It was founded in the 8th century and was long a fortified, imperial free town. The old church, monastery, and town house are still extant. Originally Esslingen belonged to the duchy of Swabia, and the Swabian League of Swabian cities and governments was formed here in 1488. There are manufactories for machinery, articles of wood, gold, silver, and tin, and also for cutlery, dye-works, and paper. Pop. (1901) 27,643.

Essonite, or **Hessonite,** a variety of garnet (q.v.), also often called Cinnamon-stone (q.v.).

Estaing, ĕs-tăṅ, **Charles Hector,** COMTE D', French army and navy officer: b. Auvergne 1729; d. Paris 28 April 1794. He entered the French army as colonel of infantry; was promoted brigadier-general in 1757, and in 1777 became vice-admiral in the French navy. In 1778, in accordance with the treaty between France and the United States, France fitted out a fleet of 12 ships of the line and 4 frigates to aid the latter in the struggle against Great Britain, and Estaing was placed in command. He sailed 13 April, reached Delaware Bay in July, and proceeded to New York. He captured some prizes off the coast of New Jersey, agreed to assist in a land and sea attack on Newport to expel the British from Rhode Island; reached the harbor late in July; and hearing of the approach of a fleet, put to sea to meet it. He was overtaken by a severe storm, which caused him to put into Boston for repairs, and the projected attack failed. Subsequently he captured St. Vincent and Grenada, West Indies, and in 1779 co-operated with Gen. Lincoln in an ineffectual attempt to capture Savannah, Ga. He returned to France in 1780; commanded the allied fleets of France and Spain in 1783; was chosen admiral of the navy in 1792; and, despite his eminent military and naval services to

France, was condemned as a royalist and guillotined in 1794.

Estancia, ĕs-tän'thē-ä, Philippines, a pueblo of the province of Iloilo, situated on the eastern coast of the island of Panay, 66 miles north of the town of Iloilo. The main portion of Estancia is one mile inland, connected by a good road with the coast and anchorage ground. Pop. 12,700.

Estate, a term sometimes used to indicate property generally, whether personal or real. Sometimes it includes land alone. It signifies in law the interest which a person may have in property. It denotes the time during which ownership may exist, as for a year, for life, or forever. At common-law estates in land are divided, as regards the quantity of interest, into two kinds, (1) freehold estates, and (2) estates less than freehold. A freehold is an estate which may last for life or longer. An estate which is circumscribed within a certain number of years, or one in which the possessor has no fixed right of enjoyment, is less than freehold, and although in fact it may last longer than the life of its first possessor, still the law regards it as a lower estate than a freehold; it is personal property in the eye of the law, and does not descend to heirs, although it may pass to executors or administrators.

Freehold estates are divided into estates of inheritance, which pass to heirs, and estates not of inheritance; the former are again divided into estates in fee simple and estates in fee tail. An estate in fee simple is the estate which a man has where lands are given to him and his heirs absolutely without any end or limit put to his estate, and it is the most extensive and the highest interest a man can have in land. If not aliened or devised, it passes to heirs generally. On the other hand, a fee tail is an estate which is limited to certain particular heirs or to a certain class of heirs, to the exclusion of the others; as to the heirs of one's body, which excludes collateral heirs, or to the heirs male of one's body, which excludes females.

In the United States fee tails have had only a limited existence, and are now in general abolished. They were changed into estates in fee simple in New York as early as 1782. Freeholds not of inheritance are for life only, either for the life of the tenant or of some other person or persons; when the estate is called an estate *pour autre vie*. Life estates are created by operation of law, or by the act of the parties. An example of an estate created by act of the parties is where A conveys land to B for the term of his natural life, or where A conveys land to B without mentioning the duration of the term. Here under the common law B would take only a life estate; but by statute in many of the States — among them New York — a grant or devise of real estate possesses all of the interest of the grantor or testator, unless the intent to pass a less estate or interest appears by express terms or by necessary implication.

Dower and courtesy are estates created by operation of law. An estate by the courtesy is that estate to which a husband is entitled upon the death of his wife in the lands or tenements of which she was seized in possession in fee simple or fee tail, during their coverture, provided they have had lawful issue born alive, and possibly capable of inheriting her estate. An estate in dower is an estate which a widow has for her life in some portion of the lands of which her husband was seized at any time during coverture, and which her issue might have inherited if she had any, and which is to take effect in possession from the death of her husband.

Estates less than freehold are divided into estates for years, at will and by sufferance. An estate for years is an interest in lands by virtue of a contract for the possession of them for a definite and limited period of time. Such estates are ordinarily called terms. The length of time for which the estate is to endure is of no importance in ascertaining its character, unless otherwise declared by statute. An estate at will is where one man lets land to another to hold at his will, as well as that of the lessee. An estate of this kind is terminated by either party on notice. Out of estates at will a class of estates has grown up called estates from year to year, which can be terminated only by six months' notice, expiring at the end of the year. An important element in creating this estate is the payment of rent. An estate at sufferance is the interest of a tenant who has come rightfully into possession of lands by permission of the owner, and continues to occupy the same after the period for which he is entitled to hold by such permission. This estate is not of frequent occurrence, but is recognized as so far an estate that the landlord must enter before he can bring ejectment against the tenant. If the tenant has personally left the house, the landlord may break in the doors, and the modern rule seems to be that the landlord may use force to regain possession, subject only to indictment if any injury is committed against the public peace.

Estates may depend upon condition; that is, their existence may depend on the happening or not happening of some event whereby the estate may be created, enlarged, or defeated. A term for years, a freehold, or a fee may thus be upon condition. The condition must either be precedent, that is, must happen before the estate can vest or be enlarged; or must be subsequent, when it will defeat an estate already vested.

Estates may also be divided into estates which are legal and those which are equitable. Estates are termed equitable when the formal ownership is in one person, while the beneficial ownership is in another. In another form of expression it may be said that a trust is created. The nature of the estate is not affected by this distinction. For example, a trust estate may be an estate for life or a fee, and in the latter case is transmissible to heirs as though it were a legal estate.

Estates are divided into estates in possession and estates in expectancy, in regard to the time of enjoyment. An estate in possession is one in which there is a present right of enjoyment. Estates in expectancy are those which give either a vested or contingent right of future enjoyment. Estates are also divided, in regard to the number of owners, into estates in severalty; in joint tenancy, in common and in coparcenary. An estate in severalty is one which has only a single owner. An estate in joint tenancy is an estate owned jointly by two or more persons, whose title is created by the same instrument. The right of survivorship is the distinguishing characteristic. When a tenant dies his interest is extinguished, and the estate goes to the survivors. Where an estate is conveyed to two or more persons, at common law, without indicating how it is to be held, it is construed to be in joint tenancy. In most of the United States, however, this rule has been changed by statute, and persons to whom an estate is conveyed or given take as tenants in common, unless they hold as trustees. An estate in common is an estate held in joint possession by two or more owners at the same time by several and distinct titles. An estate in coparcenary is an estate which several persons hold as one heir, whether male or female. This estate has the three unities of time, title, and possession. The interests, however, of the coparceners may be unequal. In the United States this estate is essentially extinguished, and heirs take as tenants in common.

Este, ĕs-tā, the name of an illustrious and ancient Italian family. Albert Azzo II. is considered the founder of the greatness of his house. He inherited or acquired Este, Rovigo, Montagnana, Casal Maggiore, and other places in Italy; and was made governor of Milan by Henry III. in 1045. One of his sons became duke of Bavaria in 1071, by the title of Welf I. He was the ancestor of the German branch of the house of Este, the dukes of Brunswick and Hanover. Albert Azzo died 1097, having previously resigned his Italian possessions to his son Fulk, and retired to Burgundy. Fulk I. was attacked by his brother Welf, who compelled him to become tributary to him to the extent of a third of his revenues. He was succeeded (1137) by his son, Obizzo I., who joined the Lombard league against Frederick Barbarossa in 1167. He d. 1193, and was succeeded by his son, who in the annals of the family is called Azzo V. Either he or Oberto acquired by marriage Ferrara, with its dependencies in Romagna, and with a feud which became hereditary with the house of Torello, for a member of which house the bride, violently carried away by the Estes, was intended. The house of Este thus became vassals of the Church as well as of the empire. He was succeeded by Azzo VI. (d. 1212). He was constantly engaged in war with the Torelli, by whom he was thrice driven from Ferrara. Aldobrandino, his son, died young, and was succeeded by his brother Azzo VII., a minor, in 1215. He was engaged in protracted wars with the Ghibelline party. Honorius VII. invested him with the marquisate of Ancona. He d. 1264, and was succeeded by his grandson, Obizzo II., who was chosen Lord of Modena and Reggio. We may pass over his successors to Niccolo III., who succeeded in 1393 at the age of nine. During his reign, and those of some of his predecessors, the house of Este became patrons of literature. He died at Milan 26 Dec. 1441. Lionel, his son (1441–50), receives a high character from Muratori for justice and piety, and for his patronage of letters. He mediated a peace in 1450 between the Venetians and Alfonso, king of Sicily; and died in November of the same year. He was succeeded by his brother, Borso (d. 20 Aug. 1471), who received new accessions of dignity from the emperor, and was created Duke of Ferrara by Pope Paul II. His reign was peaceable and prosperous. Ercole I., his brother (d. 25 Jan. 1505), succeeded, to the prejudice of his son Niccolo. His usurpation caused a war, which was unsuccessful in deposing him. He had Milan and Florence for allies, the Pope and Venice for adversaries. After the conclusion of peace in 1484 he maintained neutrality in his estates for the remainder of his reign, while the rest of Italy was convulsed with wars and revolutions. He had for his minister Boiardo, the famous author of the 'Orlando Innamorato'; and Ariosto, born near the commencement of his reign, grew up under his patronage. Alfonso I., his son, d. 31 Oct. 1534. His reign was a contrast to the peaceable one of his father. In 1509 he joined the League of Cambray, and commanded the Papal army as gonfalonier. While conducting the operations of the allies elsewhere, his estates were ravaged by the mercenary troops of Venice, whose atrocities are described in the 36th canto of the 'Orlando Furioso.' Alfonso continued in the French alliance after the Pope had joined the Venetians. He assisted in the battle of Ravenna, and took prisoner Fabrizio Colonna, the general of the Pope. After the French had been driven from Italy he endeavored to make peace with the Pope; but Julius continued implacable. Leo X. restored him to his possessions, with the exception of Modena and Reggio, but afterward excommunicated him. He joined in the wars between Francis I. and Charles V. on the side of the French king, but was afterward reconciled with the emperor, who confirmed him in his possessions, against Pope Clement VII. (1530). He married as his second wife the famous Lucrezia Borgia. His brother, the Cardinal Ippolito, was the patron of Ariosto. Alfonso was succeeded by his son, Ercole II., who died 3 Oct. 1559. He married Renée of France (daughter of Louis XII.) in 1528. She favored the Reformation, and made the court of Ferrara the resort of the few advocates of that cause in Italy. Calvin visited it in 1535. Ercole at first adhered to the imperial party, but in 1556 joined the league of Paul IV. and Henry II. of France against Spain, and was made general of the allied forces; but did not push the war with vigor, and made peace with Spain in 1558. Leonora, his daughter by Renée, was the object of the unfortunate attachment of Tasso. He was succeeded by his son, Alfonso II., the patron and persecutor of Tasso, who died 27 Oct. 1597. He was succeeded by his cousin Cesare (d. 11 Dec. 1628), whom by his testament he had made his heir; but this disposition was annulled by the Pope, Clement VIII., who excommunicated Cesare and deprived him of Ferrara, with the dependencies of the Church. Cesare was obliged to content himself with Modena and Reggio, which depended on the empire. From this period the political importance of the house of Este greatly diminishes. The last sovereign of the house was Francesco V., who succeeded in 1846. In 1859, the dynasty was deposed by the National Assembly, the duchy was annexed to Sardinia by the Treaty of Zürich 10 Nov. 1859, and has consequently been incorporated with the kingdom of Italy.

Este, Italy, a town in the province of Padua, 17 miles southwest of Padua; the ancient Adeste. Pop. about 6,000. The leaning tower, or campanile, is an interesting feature of the town, as is the battlemented mediæval fortress, known as the Rocca. Here once ruled the Este family, one of the most ancient and illustrious families of Italy. In the 11th century the house of Este became connected by marriage with the German Welfs, or Guelphs, and founded the German branch of the house of Este, the dukes of Brunswick and Hanover. The sovereigns of Ferrara and Modena were of this family, several of them being famous as patrons of letters. The lives of Boiardo, the author of 'Orlando Innamorato'; Ariosto, and Tasso were closely connected with members of this house. The last male representative of the Estes died in 1798. His daughter married a son of the Emperor Francis I. of Austria, who founded the Austrian branch of the house of Este, of which the male line became extinct in 1875.

Esters (an arbitrary modification of "ether"), COMPOUND ETHERS, OR ETHEREAL SALTS, are compounds in which one or more alcohol or basic radicals are united to one or more acid radicals. They are analogous to the salts of the metals. Thus $CH_3COO.H$ is acetic acid, and if the typical hydrogen of this acid is replaced by the monad radical "ethyl," the resulting compound, $CH_3COO.C_2H_6$, is known as "ethyl-acetic ester." Chemically, this substance is analogous to potassium acetate, $CH_3COO.K$, obtained by replacing the hydrogen of the acetic acid by potassium. The word "ester" was originally applied by Gmelin to compounds of the alcoholic radicals with oxygenated acids; but it has now been extended so as to include all the salts of the alcoholic radicals. Ethyl bromide, $C_2H_5.Br$, for example, is now included among the esters. Some of the esters are prepared by the direct action of the acid upon the alcohol. In other cases a mixture of the acid and the alcohol is distilled with the addition of sulphuric acid, zinc chloride, or other dehydrating agent. The esters may also be prepared by treating the iodide of the alcohol radical with the silver salt of the acid, the iodine and silver combining to form iodide of silver, while the liberated alcoholic and acid radicals combine to produce the desired ester. The esters of the organic acids occur in fruits and flowers, and are also prepared artificially for flavoring purposes, and for improving the bouquet of wines. The fats and oils which contain glycerine in combination with oleic, margaric and other acids may be regarded as esters, since glycerine is a triatomic alcohol. Much attention has been paid to the esters in connection with theoretical chemistry, since they are well adapted for the study of the laws of mass-action. See EQUILIBRIUM, CHEMICAL; ETHER.

Es'terhazy. See ESZTERHAZY.

Esther, or **Hadassal** (Heb. "myrtle"), the name of a Jewish maiden, chosen by Xerxes to be his queen. She was one of the heroines of Hebrew history and maintained the rights of her nation at the court of the king of Persia. See ESTHER, BOOK OF.

Esther, Apocryphal Books of. See APOCRYPHA.

Esther, The Book of, relates how a Jewish virgin, who was a foster-daughter of Mordecai, was chosen by the king of Persia, Ashauerus (Xerxes), as his wife in room of the disobedient and disgraced queen Vashti, and brought about the great deliverance of her people which is commemorated in the Feast of Purim ("lots"). Haman, the king's prime minister, had issued a decree for the extirpation of all the Jews, and had prepared to hang Mordecai; but Mordecai, who had formerly detected a conspiracy against the king's life, was raised to great honor, and Haman was hanged on the gallows 50 cubits high that he had prepared for Mordecai. After this Esther, at Mordecai's instance, revealed her Hebrew lineage, and prevailed upon the king to counteract the former edict by another permitting the Jews everywhere to destroy their enemies. The 'Book of Esther' stands conspicuous among the Hebrew scriptures as an expression of the uncompromising spirit of Hebrew nationality, containing hardly a trace of religious feeling. The name of God is not once mentioned, while the great king of Persia is referred to nearly 200 times. A possible explanation is the fact that the book was meant to be read at the merry revels of the Purim festival. It has continued in constant use and favor among the Jews, and of the five Hagiographical rolls it is called emphatically 'The Roll' (*Megillah*). The author is quite unknown, and the date is probably the latest Persian or the earliest Greek period.

Esthonia, ĕs-thō'nĭ-a̤, Russia, a maritime government, bordering on the Gulf of Finland and the Baltic. It includes several islands, of which the most important are Dagoe and Oesel; area, about 7,818 square miles. The peasantry are almost all of Finnish origin, and speak a Finnish dialect. In the 10th and 12th centuries it belonged to Denmark; it was afterward annexed by Sweden, and in 1710 was seized by Russia. Reval is the capital. (See REVAL.) Pop. 416,580. Consult: Vincent, 'Norsk, Lapp, and Finn'; Jordan, 'Beiträge zur Geographie und Statistik Esthlands.'

Estienne, ā-tē-ĕn, or **Etienne** (Lat. STEPHANUS), **Henri,** ŏṅ-rē, French painter and scholar: b. Paris 1528; d. Lyons March 1598. He was a son of Robert Estienne (q.v.) and continued his work. Beside compiling the noted 'Thesaurus linguæ Græcæ' (1572), he wrote 'Apologie pour Hérodote' (1566); 'Traité de la conformite du Français avec le Grec'; etc.

Estienne, or **Etienne** (Lat. STEPHANUS), **Robert,** rō-bār, French printer and scholar: b. Paris 1503; d. Geneva 7 Sept. 1559. In 1526 he established a printing house in Paris and in 1539 was appointed royal printer to Francis I. He removed to Geneva about 1552. He published many editions of the Greek and Latin classics and compiled numerous other works. His son HENRI took up his father's work on the death of the latter and was also a writer of note. He died in Lyons in 1598.

Estiva'tion, the dormancy or "summer-sleep," induced in some of the lower plants and animals by heat and drought, and the means by which in summer they resist these unfavorable conditions, as they do others in winter by hibernation. The two states are comparable, though induced by opposite conditions. In summer the principal danger to which such organisms are exposed is the deprivation of water. Some of the lowest are able to endure this to an extreme degree. Certain bacteria and other low plants, and various animalcules will survive prolonged baking, and may blow about in the dust of dried-up ponds for a long period, ready to revive when dampened. Among land-snails estivation is a common phenomenon, the snails protecting themselves from excessive loss of moisture, not only by burrowing into the ground, but by throwing one or several epiphragms of hardened, sometimes chalky, mucus across the aperture of the shell, thus shutting themselves into an air-tight case, where they remain inactive until better conditions arrive. In a similar manner certain fishes and amphibians bury themselves in the muddy bottom of ponds or river-pools evaporated by drought, where they preserve sufficient dampness about them to keep alive. Turtles, on the other hand, are often compelled to leave their pools in the tropics, because the water becomes so hot and full of fermentation, and seek cool spots under rocks, and the like, where they sleep torpidly until autumn. Even a few mammals of extremely hot regions, such as the deserts of Australia, go into a summer-sleep during the height of the hot season, substantially as their congeners hibernate in the midwinter of northern climates. Compare: HIBERNATION.

Estop'pel, the preclusion of a person from asserting a fact by previous conduct, inconsistent therewith, on his own part or the part of those under whom he claims, or by an adjudication upon his rights which he cannot be allowed to call in question; a preclusion, in law, which prevents a man from alleging or denying a fact, in consequence of his own previous act, allegation or denial of a contrary tenor; a plea which neither admits nor denies the facts alleged by the plaintiff, but denies his right to allege them. According to Blackstone, it is a special plea in bar, which happens where a man has done some act or executed some deed which precludes him from averring anything to the contrary. Where a fact has been asserted or admitted for the purpose of influencing the conduct or deriving a benefit from another, so that it cannot be denied without a breach of good faith, the law enforces the rule of good morals as a rule of policy, and precludes the party from repudiating his representations or denying his admissions. (Rawle, Cor. 407.)

This doctrine of law gives rise to a kind of pleading that is neither by way of traverse nor of confession and avoidance; that is, a pleading which, waiving any question of fact, relies merely upon the estoppel, and, after stating the previous act, allegation, or denial of the opposite party, prays judgment if he shall be received or admitted to aver contrary to what he before said or did. This pleading is called a pleading by way of estoppel. Until a recent period questions regarding estoppel arose almost entirely in relation to transfers of real estate, and the rules in regard to one kind of estoppel were quite fully elaborated. The principle is now applied to all cases where one by words or conduct wilfully causes another to believe in the existence of a certain state of things, and induces him to act on that belief or to change his own previous situation.

Estoppels operate not only on present interests, but on rights subsequently acquired. They operate, however, only between parties and privies, and the party who pleads the estoppel must be one who was adversely affected by the act which constitutes the estoppel. An estoppel may be by record, and by record in this connection is meant the record of a tribunal of a judicial character. An admission made in a pleading in a judicial proceeding cannot be contradicted by the person making it. So, ordinarily, the judgment of a court of competent jurisdiction cannot be impeached. If it determines the status of a person or thing, it is binding on all persons, whether rendered by a domestic or a foreign court. Judgments of this character are judgments *in rem.* If the judgment is *in personam,* it is conclusive if rendered by a domestic tribunal, and is conclusive in some instances if rendered by a foreign tribunal. Legislature records also import absolute verity. (Bigelow on Estop. 33.)

An estoppel by deed is such as arises from the provisions of a deed. It is a general rule that a party to a deed is estopped to deny anything stated therein which has operated upon the other party, as the inducement to accept and act under such deed, including a deed made with covenant of warranty, which estops even as to a subsequently acquired title. The deed must be good and valid in its form and execution to create an estoppel, and must convey no title upon which the warranty can operate in case of a covenant.

Estoppels must be reciprocal. An estoppel *in pais,* or equitable estoppel, occurs when a party to an action has by his act or declaration induced the other party to do some act or acts which otherwise would not have been done, or to omit to do some act or acts which he would have done, and by means of which he has been injured. The principle underlying such estoppels is, that it would be a fraud in a party to assert what his previous conduct and admission have denied, when, on the faith of that denial, others have changed their situation. There must, however, as a rule, be some intended deception in the conduct or declarations of the party to be estopped, or such gross negligence on his part as to amount to constructive fraud, by which another has been misled to his injury.

Estotiland, a mythical land, placed by the old geographers where is now portions of Newfoundland, Labrador, and that part of British America bordering on Hudson Bay. It was said to have been discovered by two Friesland fishermen driven out of their course by a storm, two centuries before the time of Columbus. In 1497 the Cabots set sail from England for Estotiland, but discovered instead Newfoundland.

Estremadura, ĕsh-tra-mä-doo'rä, Portugal, a maritime province divided by the Tagus into two nearly equal parts, of which the north is the more mountainous. Wines and olives are the principal produce. The chief city is Lisbon. Area, 6,876 square miles; pop. (1900) 1,232,593.

Estremadura, ā-strā-mä-doo'rä, a division of Spain, in the southwest, consisting of two provinces, Badajoz and Caceres. The northern part has large forests, and in the central and southern parts are some good agricultural lands. Deposits of coal, copper, and silver are found in the mountains; but the mines are not well developed. Area, 16,700 square miles; pop. 845,873.

Es'tuary. Where a shore-line is sinking or has been recently depressed, the rivers, unless large and heavily charged with sediments, have their valleys drained by the encroaching sea, forming roughly funnel-shaped bays. Such bays are called estuaries, and are common along the sinking Atlantic coast of North America. Illustrations are seen in Passamaquoddy and Narragansett bays, the mouth of the Hudson River, Delaware and Chesapeake bays. Owing to their shape, estuaries frequently have strong tidal currents, due to the height of the tides, and the rising tide rushes in as waves, the most remarkable examples of such surf-like tidal waves, or bores, being found in the Bay of Fundy. The rivers entering estuaries drop much of their fine sediment there because of the checking of their currents and the precipitating effect of salt water. The strong tidal currents sweep away and rearrange these sediments. Hence conditions on the bottoms of estuaries are often unfavorable for the growth of organisms, and the estuary deposits of past ages are seldom rich in fossils, but may contain remains of land organisms brought down by the old river; and the tidal mud-flats have preserved the prints of raindrops, the traces of worms, and the tracks of birds and reptiles. See River.

Eszterhazy, ās-tār-ä-zē, or ĕs'tĕr-hä-zī, **Marie Charles Ferdinand Walsin,** forger: b. Austria 16 Dec. 1847. He served in a regiment of Papal Zouaves during the latter part of the French empire; was promoted commander, a rank equivalent to major in other armies, in 1892. In the early part of 1897 he was retired from the army. He became known throughout the civilized world through his connection with the trial of Capt. Alfred Dreyfus (q.v.), whom he accused as being the writer of the famous "bordereau," alleged to have been sent to certain German military officers revealing French military secrets. In December, 1894, Dreyfus was tried by court-martial and convicted as the author of the document, and on 5 Jan. 1895 was publicly degraded and a little later sent as a prisoner to Devil's Island. In 1896, Col. Picquart, the head of the intelligence bureau of the war office, made certain discoveries which pointed to Maj. Eszterhazy as the author of the "bordereau." These discoveries led to further investigation and Dreyfus was brought from his prison and given a new trial in 1899, but was again convicted, although much of the evidence gathered pointed to Eszterhazy as the forger of Dreyfus' handwriting and as the real traitor. So strong did this opinion become that Eszterhazy was compelled to leave France.

Eszterhazy von Galantha, ĕs'tĕr-hä-zī fōn gä-län'tä, a family of Hungarian magnates, afterward princes of the German empire, whose authentic genealogy goes back to the first half of the 13th century. They were zealous partisans of the house of Hapsburg, to whom, during the reigns of Frederick II. and Leopold I., they lent a powerful support. In 1238 Peter and Elias, sons of Salomon von Estoras, divided their father's inheritance. The former obtained Zerhaz, the latter Illyeshaza, and thus became the founders of two principal lines, the latter of which became extinct in the male line in 1838, with Count Stephen Illeshazy. Peter's descendants took from their domain the name of Zerhasy, till Francis Zerhazy (b. 1563; d. 1595), vice-regent of the county of Presburg, changed this name into Eszterhazy in 1584, on the occasion of his being named Lord of Galantha. Among noted modern inheritors of the name are Paul IV., Prince Eszterhazy, a general and literary savant (1635–1713). His grandson, Nicholas Joseph, a great patron of arts and music, founder of the school in which Haydn and Pleyel, among others, were formed (1714–90). Nicholas, Prince Eszterhazy, distinguished as a field marshal and foreign ambassador (1765–1833). Prince Paul Anthony, a distinguished and able diplomatist (1786–1866), successively Austrian ambassador at Dresden, Rome, and Britain, and a supporter of the National Hungarian movement.

Eszek, es'sĕk, or **Esseg,** Austria-Hungary, a royal free city in Croatia and Slavonia, capital of the county of Veröcze, on the Drave, about 63 miles west-northwest of Peterwardein. It consists of the town proper, partially fortified, and three suburbs, and is the seat of an appeal court for three countries. It has a normal school for the training of teachers. The manufactures are not extensive; but the four annual fairs, chiefly for corn, cattle, and hides, are important. As a Roman colony, founded by the Emperor Adrian, under the name of Mursia, it became the capital of Lower Pannonia, and in 335 was made a bishop's see by Constantine. Pop. 23,216.

Etampes, Anne de Pisseleu, än dė pēs-sē-lė ā-täṅp, Duchesse d', French royal favorite: b. about 1508; d. about 1576. She became the mistress of Francis I., but to save appearances he gave her for a nominal husband Jean de Brosse, afterward Duke d'Etampes. The new duchess wielded a paramount influence in the affairs of the nation. Upon the fine arts and in some other directions she exerted a good influence, but the jealousy between her and Diana of Poitiers, the mistress of the Dauphin Henry, became a source of calamity for France. It was chiefly under the influence of this feeling that she betrayed to Charles V. the movements of the French army; and the disadvantageous treaty of Crécy in 1544 was due to the intrigues of Anne and of Diana.

Etampes (ancient Stampæ), France, a town in the department of the Seine-et-Oise, at the confluence of the Etampes and Juine, southwest of Paris. It has four Gothic churches, one of them a remarkable structure of the 13th century; tanneries and bleacheries, and a considerable trade in corn, flour, and prepared wool. Pop. 9,310.

Etang, ā-täṅ, is a French geographical term applied to the remarkable salt lagoons and marshes on the south and west coasts of France. The stagnant seawater is generally utilized, as in Brittany and in the department of Bouches-de-Rhone, for the manufacture of salt. The principal lagoons of this character in France are the Etangs de Berre, de Sigean, de la Palme, and de Leucate on the south, and de Heurtin, de Cazan and de Parentes on the west coast.

Etawah, ĕ tä'wä, India, a town in the northwest provinces, 70 miles southeast of Agra, capital of the district of Etawah, situated on the Jamna River. It was once the residence of many of the Mogul grandees, and it is now an important trade centre. Pop. (1891) 38,793.

Etching, the art of producing designs on a plate of steel or copper by means of lines drawn with an etching needle (a fine-pointed steel tool), the lines being drawn through a coating or varnish (the ground), and bitten in by some strong acid which can only affect the plate where the varnish has been removed. See ENGRAVING.

Eteocles, ĕ-tē'ō-klēz, and **Polynices,** pŏl-ī-nī'sēz, two heroes of ancient Greek legend, sons of Œdipus, king of Thebes. After their father's banishment from Thebes, Eteocles usurped the throne to the exclusion of his brother, an act which led to what was known as "The Expedition of the Seven Against Thebes," Polynices being one of the seven leaders. The two brothers fell by each other's hand. The interment of Polynices was forbidden under penalty of death but Antigone (q.v.), his sister, braved the doom decreed. Racine has dramatized this story with some poetical variations in his 'Frères Ennemis.' See ADRASTUS.

Eternal City, The, Rome, the capital of Italy. Legend states that it was raised by or under the immediate supervision of the immortal gods. The term is frequently to be met in classic literature. 'Ave, Roma Immortalis' is the title of a historical work on the Italian capital, by Francis Marion Crawford. 'The Eternal City' is the title of a novel by Hall Caine, published in 1901, the scene of which is laid in Rome. It was dramatized and produced simultaneously in England and in the United States in 1902.

Ete'sian Winds, winds blowing at stated times of the year; applied especially to north and northeast winds which prevail at certain seasons in the Mediterranean regions.

Etex, Antoine, äṅ-twän ā'tĕks, French sculptor, painter, architect, engraver and writer: b. Paris 20 March 1808; d. Chaville 16 July 1888. He took the second grand prize of Rome (1829) with his 'Dying Hyacinthe'; and became a member of the Legion of Honor (1841). Among his other works in sculpture are: 'Cain and His Cursed Race' (1833); 'Resistance of France to Coalition of 1814'; and 'Peace,' for the Arc de l'Etoile; group, 'City of Paris Imploring God for Victims of Cholera'; 'Charlemagne'; equestrian statue of Charles I. Among his paintings are: 'Romeo and Juliet'; 'Faust and Marguerite'; 'Allegorical Glory of the United States,' for City Hall, New York (1853). Among his literary works are: 'Notes on Paul Delaroche' (1857); 'Study of Life and Works of Ary Schæffer' (1859); 'Textbook for the Polytechnical Association, for Students and Workmen' (1861).

Ethane, C_2H_6, a gaseous hydrocarbon belonging to the paraffin series and constituting its second member (the first being methane, or marsh-gas). It occur in the gases that are given off by crude petroleum, and it may be prepared by heating methyl iodide with metallic zinc in closed tubes at 300° F.; the iodide of methyl that is required being obtained by acting upon methyl alcohol (see ALCOHOL) with iodine, in the presence of phosphorus. Ethane is also liberated at the anode, together with carbon dioxide in the electrolysis of a concentrated solution of sodium acetate. It is a colorless gas, which burns with a pale flame, and combines with water, under pressure, to form a crystalline hydrate. At a temperature of 39° F. it may be liquefied by a pressure of 47 atmospheres. Chlorine combines with ethane rapidly, in diffuse daylight, with the formation of ethyl chlorid, C_2H_5Cl; but if excess of chlorine is present, higher substitution products are also formed, terminating with hexachlorethane, C_2Cl_6. Ethane is also known as "ethyl hydrid."

Eth'elbald, king of Wessex: d. 860. He was a son of Ethelwulf, king of the Anglo-Saxons, and obtained the throne of Wessex in 856. While Ethelwulf was making a journey to Rome, Ethelbald formed the project of seizing the throne. A civil war was prevented only by the moderation of Ethelwulf, who resigned to his son the dominion of Wessex, and confirmed that portion of the kingdom to him in his will. The reign of Ethelbald was peaceful, but he excited general disapprobation by marrying, contrary to the canonical law, his stepmother Judith. Ecclesiastical and popular displeasure forced him at length to a separation, and Judith returning to France, eloped from a convent with Baldwin, afterward count of Flanders. From this union descended Matilda, wife of William the Conqueror, and through her the race of English sovereigns.

Eth'elbert, king of Kent: b. about 552; d. 616. He married Bertha, the daughter of Charibert, king of the Franks, and a Christian princess, who, stipulating for free exercise of her religion, brought over with her a Frankish bishop. Her conduct was so exemplary as to prepossess the king and his court in favor of the Christian religion. In consequence, Pope Gregory the Great sent a mission of 40 monks, headed by Augustine, to preach the gospel to the Saxons (597). They were well received, and numbers were converted; and the king himself at length submitted to be baptized. Civilization and knowledge followed Christianity, and Ethelbert, about 600, enacted a body of laws, which was the first written code promulgated by the northern conquerors. At the time of the landing of Augustine, he had acquired a supremacy over all the English south of the Humber. Ethelbert founded the see of Rochester in 604, and afterward that of London. He was succeeded by his son, Eadbald.

Ethelbert, king of Kent and Wessex: d. 866. He was the third son of Ethelwulf, and succeeded to the government of Kent about 855; and in 860, on the death of his brother Ethelbald, became king of Wessex. His reign was much disturbed by the inroads of the Danes, whom he repulsed with vigor, but without permanent success, as, whenever they were driven from one part of the country, they ravaged another.

Eth'elred I., king of England: d. 871. He was the fourth son of Ethelwulf, and succeeded his brother Ethelbert in 866. Assisted by his brother Alfred, Ethelred drove the Danes from the centre of Mercia, where they had penetrated; but, the Mercians refusing to act with him, he was obliged to trust to the West Saxons alone, his hereditary subjects. Notwithstanding various successes, especially a great victory at Ashdown, the invaders continually increased in numbers. Ethelred died, in consequence of a wound received in an action with them, and was succeeded by Alfred.

Ethelred II., king of England: b. 968; d. London 23 April 1016. He succeeded his brother, Edward the Martyr, in 978, and, for want of sound judgment and sagacity, was surnamed the "UNREADY" (without *rede* or counsel). About 981 the Danes, who had for some time ceased their inroads, renewed them with great fury. In his reign began the practice of buying them off by presents of money. After repeated payments of tribute (see DANEGELD) he effected, in 1002, a general massacre of the Danes in England. Such revenge only rendered his enemies more violent; and in 1003 Sweyn and his Danes carried fire and sword through the country. They were again bribed to depart; but, upon a new invasion, Sweyn obliged the nobles to swear allegiance to him as king of England; while Ethelred, in 1013, fled to Normandy with his family. On the death of Sweyn, in 1013, he was invited by the national council to resume the government. Ethelred, in 1002, married, as his second wife, Emma, sister of the Norman Duke Richard II.

Ethelre'da, Saint, East Anglian princess: d. Exning, Suffolk; d. Ely 23 June 679. Although twice married she made and kept the monastic vow of chastity and continence. She finally became abbess of Ely, and the county fair which was held all over the land on her day, after her canonization as Saint Ethelreda or Audrey, gave rise to the expression "tawdry," as indicating something cheap and fine, such as would be offered for sale in a village booth.

Eth'elwulf, king of England: d. 858. He succeded his father, Egbert, in 839, and soon after his accession associated his son Athelstan with him, giving him the sovereignty over Essex, Kent, and Sussex. In 851 the Danes poured into the country in such numbers that they threatened to subdue it; and though opposed with great vigor by Athelstan, they fixed their winter quarters in England, and next year burned Canterbury and London. After inflicting a great defeat on the Danes at Ockley, he went on a pilgrimage to Rome, and on his return found his son Ethelbald in revolt against him. In order to avoid a civil war, he gave up the western division of the kingdom to his son, retaining Kent for himself. Before going to Rome, Ethelwulf had made certain grants, which used to be regarded as the first payment of tithes in England; but modern authorities reject this view.

Ethendun, Battle of, the victory which Alfred the Great gained over the Danes (878), and which led to the treaty with Guthrum, the Danish king of East England. The locality where the battle was fought is supposed to be at Edington, in Wiltshire.

E'ther, in chemistry, any compound which may be regarded as derived from water by the replacement of each of the hydrogen atoms by a basic or alcoholic radical. The ether is "simple" if the basic radicals that are so substituted are alike, and it is "mixed" if they are unlike. The formation of a simple ether may be conveniently illustrated by the case of common, or "diethyl" ether, $(C_2H_5)_2O$. This may be prepared in various ways, but the sulphuric-acid method will serve best to illustrate the nature of the compound. When alcohol, $C_2H_5.OH$, is heated to 285° F. with sulphuric acid, H_2SO_4, one of the hydrogen atoms of the acid is replaced by the alcohol radical ethyl C_2H_5, according to the equation $C_2H_5.OH + H_2SO_4 = (C_2H_5)HSO_4 + H_2O$, the compound $(C_2H_5)HSO_4$ being known as hydrogenethyl-sulphate, or "sulphovinic acid." When the hydrogen-ethyl-sulphate comes in contact with another molecule of the alcohol, it undergoes a second transformation, by which another ethyl radical is taken up, and a molecule of sulphuric acid again set free, as indicated by the equation. $(C_2H_5)\ HSO_4 + C_2H_5.OH = (C_2H_5)_2O + H_2SO_4$. It will be seen that although a molecule of sulphuric acid is used up in the first part of the process, it is regenerated in the second part, so that on the whole there has been no change in the quantity of acid present. The water produced in the first stage, and the ether, $(C_2H_5)_2O$, produced in the second stage, pass off in the state of vapor, and the apparatus is ready for the admission of a new supply of alcohol. The process by which an ether is formed, as here illustrated, is called etherification; and the etherification is said to be "continuous" if it can go on, as in this case, by merely passing a stream of the alcohol into one end of the apparatus, and withdrawing the vapor of ether and water at the other end. Methyl ether, for example, can be formed by the action of sulphuric acid upon methyl alcohol in a manner precisely analogous to that explained above. The equations in this case are $CH_3.OH + H_2SO_4 = H_2O + (CH_3)\ HSO_4$; $(CH_3)HSO_4 + CH_3OH = H_2SO_4 + (CH_3)_2O$; where $CH_3.OH$ is methyl alcohol, $(CH_3)_2O$ is methyl ether, and $(CH_3)HSO_4$ is hydrogen-methyl-sulphate.

As an illustration of a mixed ether, the case of methyl-ethyl ether may be cited. If ethyl alcohol be heated with iodine in the presence of phosphorus, a substance known as ethyl iodide is formed. Thus: $5C_2H_5.OH + 5I + P = 5C_2H_5.I + H_3PO_4 + H_2O$. On the right of this equation, H_3PO_4, is phosphoric acid, and $C_2H_5.I$ is ethyl iodide, which is a liquid boiling at 152° F., readily separable from the phosphoric acid by distillation. Now if ethyl iodide be mixed with potassium ethylate (obtained by dissolving metallic potassium in absolute ethyl alcohol), the following reaction occurs, and ethyl ether is formed: $C_2H_5.I + C_2H_5.OK = KI + (C_2H_5)_2O$. But if the ethyl iodide is mixed with potassium *methylate*, $CH_3.OK$, which is obtained by dissolving metallic potassium in absolute methyl alcohol, then the ether that is formed contains the radical methyl, CH_3, and also the radical ethyl C_2H_5, and hence is a mixed ether; $C_2H_5.I + CH_3.OK = KI + C_2H_5.O.CH_3$. The mixed ether, $C_2H_5.O.CH_3$, is known as methyl-ethyl ether. The reactions that have here been given at some length are typical of similar ones that hold true very generally of the alcohols and ethers. In all the more familiar cases the iodide of a given alcohol radical can be prepared by treating the corresponding alcohol with iodine and phosphorus; and a potassium "alcoholate" can be formed by dissolving metallic potassium in the corresponding (anhydrous) alcohol. Then if we wish to prepare a proposed mixed ether, we have only to treat the iodide of one of its radicals with the potassium compound of the other one, as indicated above. The commoner ethers, both simple and mixed, strongly resemble one another in their general properties. Thus they will not mix with water, nor combine with ammonia nor other alkalis, nor with metallic sodium, nor with dilute acids. The resemblance is also close in other respects. (For "compound ethers" see ESTERS.)

Ethyl Ether, Diethyl Ether, or Sulphuric Ether.— When the term ether is used without qualification, diethyl ether, $(C_2H_5)_2O$, is universally understood to be meant, just as ethyl alcohol is understood, when alcohol is mentioned without qualification. The preparation of diethyl ether, by the action of sulphuric acid upon alcohol, has already been described. The substance so obtained is a mobile, colorless, inflammable and very volatile liquid, with a specific gravity of about 0.72 at ordinary temperatures. It will not mix with water to any great extent, but will mix readily with many organic fluids, and also with liquid carbon dioxide. It dissolves resins and fats, and many of the alkaloids. It boils at 95° F., under a pressure of one atmosphere, and at 200° F. below zero it freezes into a crystalline solid, which melts again at about 180° F. below zero.

CHARLES MOHR, M.D.,
Hahnemann Hospital, Philadelphia.

Ether, in physics, a hypothetical substance, probably devoid of weight, which is supposed to fill all space, and to penetrate freely among the ultimate particles of which matter is composed. It is not in any way related to the substance known as "ether" to the chemist, and the identity in name is unfortunate. The physicist has the advantage of priority, however, and cannot be expected to change the name because the chemist subsequently appropriated it for something else. Although we know very little about the precise properties of the ether of physics, the admission of its existence is almost a necessity of thought. For we know that light is some kind of a periodic disturbance, and we know that it travels through interstellar space with a definite, finite speed. It would manifestly be absurd to suppose that a motion of any kind could take place in a void, in which there was nothing to be moved; and hence, as has been said, it appears to be a logical necessity to admit the existence of some kind of a luminiferous (light-bearing) ether throughout space. As soon as we begin to inquire closely into its nature, however, we encounter difficulties that have thus far proved insuperable. Obviously our conclusions in this respect will depend to a large extent upon a study of the phenomena of light, and of the kind of motion that would be competent to produce those phenomena. Naturally the assumption was first made that the ether, when submitted to stress, conforms to the same laws of elasticity that hold true in ordinary matter. (See ELASTICITY.) In that case the full mathematical theory of the motion of the ether would involve no less than 21 numerical coefficients, if the ether were anisotropic. But there is every reason to believe that, whatever its nature may be, it is the same in all its parts, and that its properties, whatever they may be, are the same in all directions. If these two facts are admitted — that is, if the ether be admitted to be isotropic — then the number of constants involved in the theory reduces to two. These, as is explained in the article ELASTICITY, are (1) the modulus of compressibility, and (2) the modulus of rigidity. If the ether were analogous to a liquid or a gas, its modulus of rigidity would be zero. It is found, however, that the equations of motion that are obtained by making the modulus of rigidity zero are not at all competent to explain the actual phenomena of light; for in this case the ether-waves would be merely waves of alternate compression and rarefaction, like those of sound in the air, and there could be no such phenomenon as polarization. It must therefore be admitted that the modulus of rigidity of the ether has a definite, finite value, if the ether itself is to be regarded as analogous to other kinds of matter, so far as its general mechanical deportment is concerned. If it be also admitted that the modulus of compressibility of the ether has a definite, finite value, the conclusion is reached that the ether can transmit two essentially different kinds of waves, one of which involves distortions of its parts, while the other involves changes in its density. Of these the first would admit of polarization, while the second would not. Moreover, the two kinds of waves would have, in general, different velocities of propagation; and the fact that all ether-disturbances appear to be propagated at the same speed indicates that only one kind exists, and that we must therefore make one of the three following assumptions with regard to the compressibility of the ether: (1) The modulus of compressibility of the ether is infinite; or (2) it is zero; or (3) the circumstances under which the atoms (or their component electrons) impress their motions upon the ether are such that the modulus of compressibility is not involved in any way. The first of these alternatives implies that the ether is absolutely incompressible, and this is the one that has been most favorably regarded by physicists in general. The second implies that the ether yields indefinitely, even to the smallest compressive forces, so that it is essentially unstable. This view has been developed in recent years by Lord Kelvin, but it is hard to regard it as more than a mathematical possibility. The mind almost refuses to admit that it corresponds to the actual state of affairs in space. The third of the suggested alternatives must also be regarded as improbable, although perhaps we can hardly pronounce it impossible. On the whole, therefore, it is plain that if the elastic behavior of the ether is analogous to that of ordinary bodies, we have to admit (tentatively, at least) that so far as elastic properties are concerned, the ether resembles an absolutely incompressible solid. In the article 'Ether,' in the 'Encyclopædia Britannica,' Maxwell gave estimates of the density and modulus of rigidity of the ether, and these estimates have been widely copied in works on physics, without question, although the computation upon which they are based contains several arithmetic errors. Correcting these, his estimate of the density of the ether becomes 106×10^{-20}, that of water being unity; and his estimate of the modulus of rigidity becomes (when expressed in C. G. S. units) 955, the modulus of rigidity of glass, in the same units, being 24×10^{10}. Roughly, therefore, the calculation may be said to indicate that the ether is about one 1,000,000,000,000,000th as dense as air, and about one 240,000,000th as rigid as glass. Maxwell's computation, however, assumes that the amplitude of an ether-wave is one $\frac{1}{100}$ of its length, and this is a subject upon which we can hardly form an intelligent guess. There does not appear to be any sufficient reason why he could not equally well have taken the amplitude equal to the 100,000th of the wave-length; and if he had done this, he would have concluded the density of the ether to be one 1,000,000,000th of that of air, and its rigidity to be one 240th of that of glass. These numerical estimates are therefore of no particular value. It is not likely, however, that the amplitude of an ether-wave is greater than the value that Maxwell assumes, and hence his results may be taken as minimum limits to the values of both the density and the rigidity of the ether, on the supposition that the assumed analogy of the ether to an incompressible elastic solid is defensible.

According to the elastic-solid theory of the ether, light consists of a periodic or wave-like disturbance in a jelly-like medium, the waves traveling in straight lines with a uniform velocity of about 186,000 miles per second, and the direction of oscillation of the ether being at right angles to the direction in which the wave progresses, just as the direction of oscillation of the various points of a rope along which a wave is passing is at right angles to the rope. This view of the case accords very well with most of the observed phenomena, but there are some that do not appear to be reconcilable with it. We believe that the ether penetrates all bodies, and fills up the spaces between their molecules (or electrons); and as the phenomena of refraction show that the velocity of light is less in a transparent solid (say in glass) than it is in a vacuum, it follows that the ether in the glass has either a greater density or a less rigidity than it has in free space. Either of these suppositions will fit this simple case equally well; but there are other phenomena that will not be satisfied so easily, and it has been found to be impossible to make any single set of consistent assumptions which shall reconcile the "elastic-solid" theory of the ether with all the known facts. For example, when we come to investigate certain problems in partial reflection from transparent media, and others relating to diffraction from small particles, we are obliged to conclude that it is the density of the ether that varies, the rigidity remaining practically constant. On the other hand, the phenomena of double refraction require us to admit that the rigidity of the ether in a doubly refracting body is different in different directions; and hence we conclude that the rigidity of the ether is modified by the presence of molecules of matter — a conclusion at variance with that previously reached by considering the phenomena of diffraction and partial reflection. Other difficulties have been encountered in the application of the elastic-solid theory of the ether to the phenomena of light, and although reference to it is common, because it is definite enough to present a clear image to the mind, and so is helpful in many ways, the general opinion among physicists of the present day is that it is no longer tenable as an accurate description of the real properties of the ether. It has been abandoned in favor of the "electro-magnetic" theory of Maxwell, and in abandoning it we also abandon the method of estimating the density and rigidity of the ether to which reference has been made, above.

Faraday was convinced, many years ago, that there is some mechanism by which magnetic and electric forces are enabled to make themselves felt through a space apparently vacuous. "Such an action," he said, "may be a function of the ether; for it is not unlikely that, if there be an ether, it should have other uses than simply the conveyance of radiation." Maxwell, after reading Faraday's writings, became so impressed by the ideas which they advanced that he applied his own ingenious and powerful mind to the problems whose solution Faraday had dimly glimpsed, and succeeded in completely revolutionizing our ideas with regard to light and the ether. His now famous "electro-magnetic theory" is given in his masterly but exceedingly difficult 'Treatise on Electricity and Magnetism,' and a popularized account of it may be found in Oliver J. Lodge's 'Modern Views of Electricity.' He agrees with previous writers that light is some sort of a periodic disturbance in some sort of an ether, and that the displacements that occur are indeed perpendicular to the direction in which the light-wave travels; but he teaches us that these displacements are not analogous to those that are produced in an elastic solid when that solid is deformed. He considers that they are of an electrical nature, and that we must learn about them not by observing the behavior of elastic bodies under stress, but by observing the phenomena exhibited by electrified bodies. Maxwell has given us the fundamental equations that must be satisfied when an electrical disturbance is propagated through the ether, and by means of these equations the entire theory of light can be constructed on the new basis. The theory thus constructed agrees well with the facts of observation, and it is free from the objections that beset the old elastic-solid theory. Moreover, it successfully withstood the searching experimental tests devised and executed by Hertz and his followers, whose labors have shown us that electrical radiations are propagated with the same speed as light, and that they can be reflected, refracted, diffracted, polarized, and made to interfere; so that we are now quite ready to admit that light consists in a rapid succession of such radiations. It is not at all essential to Maxwell's theory that we should know precisely what an "electrical displacement" really is, and hence it does not teach us so much about the nature of the ether as we might expect. It does teach that the elastic-solid analogy is probably not correct, and it strongly suggests that the ether is incompressible, and that there is some kind of an ethereal rotation going on in a magnetic field; but it has not yet been made to furnish a means of estimating the density of the ether, nor of obtaining any of its other constants.

We do not even certainly know whether the ether is continuous, or whether it is molecular in structure. Some writers find it difficult to think of a displacement of any kind, in a space that is entirely filled with matter, especially if the matter is incompressible. Others hold that this objection is without weight.

Faraday's idea that magnetic and electric induction are propagated by the same medium as light proved to be exceedingly fruitful, and it is by no means unlikely that the ether possesses still other functions, which will throw further light upon its nature, when they are understood. The various kinds of radiations that have been discovered in recent years ("cathode rays," "Becquerel rays," "X-rays," and the like) were at first believed by many authorities to consist in ethereal motions different from those constituting light, and it was even thought that some of them might correspond to the waves of ethereal compression that had been so earnestly sought. Some of these radiations, however, are now believed to be nothing but ordinary light of exceedingly short wave-length, and others are believed, at least tentatively, to consist in the actual emission of storms of corpuscles, or «electrons,» from the bodies from which they proceed. (See ELECTRON; RADIUM; RADIATION.) Gravitative action has also been attributed to ether stresses, and it is indeed probable that this is its real nature. No mechanical explanation of gravitation, as an ether-phenomenon, has yet been offered, however, to which serious objections cannot be urged. In Maxwell's theory of gravitation it is assumed that bodies produce a stress in the ether about them, of such a nature that there is a pressure along the lines of gravitative force, combined with an equal tension in all directions at right angles to those lines. «Such a state of stress,» says Maxwell, «would no doubt account for the observed effects of gravitation. We have not, however, been able, hitherto, to imagine any physical cause for such a state of stress.» He calculates that to produce the actual effects of gravity, as observed at the surface of the earth, the ether would have to be subject to a pressure of 37,000 tons per square inch in a vertical direction, and a tension of the same numerical magnitude in all horizontal directions.

One of the most obvious difficulties in the way of the ether-theory is that the planets, and even the atoms, move through space as though it were absolutely empty. According to modern notions, however, the atom may be only an aggregate of still smaller «electrons,» each of which may transpire to be nothing but a state of strain in the ether; and if this proves to be the case, we are certainly not in position at present to say that the ether would oppose in the slightest degree the transmission of such a state of strain through its own substance. The difficulty with the theory of aberration is more formidable. If a shower of rain is falling vertically, the drops will appear to an observer to descend vertically so long as he remains stationary. If he moves forward, however, the drops will strike him in the face, and will therefore appear, to him, to come from some point slightly in advance of the zenith, rather than from the zenith itself. A similar phenomenon is observed in connection with light, and is known as aberration. Every star is seen in its true position when the earth is moving directly toward it; but three months later, when the earth is moving at right angles to this direction, the observer's telescope will have to be inclined slightly toward the direction in which the earth is moving, in order that the light from the star may come down through the instrument centrally. The maximum displacement that a star can have, from this cause, is known by observation to be about 20.47 seconds of arc on the heavens. If the ether were motionless, the analogy with the rain-drops would be perfect, and the «constant of aberration,» whose value has just been given, could be calculated from the known velocity of light, and the known velocity of the earth's orbital motion. It is found, however, that the theory of aberration is exceedingly complicated when the possibility of currents in the ether is admitted, and hence physicists have been much concerned to know whether or not the earth drags the adjacent ether along with it, in its motion around the sun. As long ago as 1859 Fizeau showed, by a justly celebrated experiment, that the ether is apparently dragged along by a current of water flowing through a tube; and Michelson and Morley have since shown, by an even more ingenious experiment, that there is evidence that the ether in the immediate vicinity of the earth participates in the earth's motion to such an extent that any difference that may exist does not amount to the twentieth part of the whole motion. Lodge, on the other hand, found no evidence of any "ether drag" in the space between two rapidly whirled steel plates that were separated by an interval of one inch. (See Preston, 'Theory of Light.') The whole subject of the "drag" of the ether is still unsettled; but the observed value of the constant of aberration appears to require that the ether is not disturbed by the motion of the earth through it.

The most noteworthy book on the ether, in recent times, is Larmor's 'Æther and Matter,' which (like all other advanced works on the same subject) is difficult reading. Consult, also, Drude, 'Physik des Æthers.'

Etherege, ĕth'ėr-ej, SIR **George,** English dramatist: b. about 1635; d. 1691. In 1664 appeared his first comedy, 'The Comical Revenge, or Love in a Tub'; an incongruous mixture of prose and verse, but suited to the taste of the times, and well received. The author was immediately enrolled among the courtly wits of the day, and in 1668 brought out 'She Would if She Could,' which was very coarse and licentious. In 1676 he produced his third and last comedy, entitled 'The Man of the Mode, or Sir Fopling Flutter.' This performance was still more applauded than the preceding, and the Sir Fopling was, for a long time, deemed the ideal of the superlative beau or coxcomb of the age. Etherege's plays are little more than lively conversation pieces, with a great paucity of genuine humor or felicitous plot.

Ethical Movement and Ethical Societies in America and Abroad. The first Ethical Society was established and the Ethical Movement inaugurated in 1876 in New York by Felix Adler, then a lecturer at Cornell University. In response to a call, several hundred persons met in May at Standard Hall, and at the conclusion of Prof. Adler's address, outlining the purpose and spirit of the proposed organization, the Society for Ethical Culture of New York was constituted. In this address he appealed to his auditors to unfurl a new flag of peace and conciliation over the bloody battlegrounds where religions had fought in the past; he laid stress upon the urgent need of a higher and sterner morality to cope with the moral perils of the hour, especially noting the growing laxity that accompanied the decline of discredited forms of religious belief; and he placed peculiar emphasis upon the duty of caring for the moral education of the young. The society thus initiated grew rapidly, and soon gave practical effect to his programme. Within a few years it had established a free kindergarten for the children of the poor, the first of its kind in New York; and this developed into a workingman's school, based upon the Froebelian pedagogy, which was the first school to introduce manual training and systematic ethical instruction into the curriculum. It also inaugurated a system of trained nurses for the poor, which has since become an adjunct of dispensary out-door relief in the city. Nor were the larger social and political applications of morality to contemporary life neglected: its leader devoting special attention in his platform utterances to the labor problem and specific social reforms, as being at bottom great moral issues. His vigorous exposure of the evils of the tenement houses bore fruit in the creation of the Tenement House Commission of 1884, of which he was appointed a member. He also was among the first advocates of small parks in the congested districts, of public playgrounds and public baths; and, above all, of greater justice and humanity in the relations between labor and capital, employer and employed. The Labor party here found a new type of advocate; and reformers and politicians a platform from which the issues of the hour were brought to the touchstone of ethical first-principles.

Meanwhile, the society filled more and more the place of a church in the lives of its hitherto unchurched members. It did not neglect the problems of the personal life; but aimed to illuminate and inspire its members in their dealings with the problems of the home and the vocation, family relations, marriage, the training of the young, etc. Its position as a distinctive religious organization became better understood and its religious appeal more forcibly felt, while its practical educational and philanthropic activities continued to multiply. Its schools, testifying to its conviction that moral improvement must begin with the care and education of the young, expanded until kindergarten, normal and high school departments were added. These have for some time been inadequately housed. The Sunday audiences, too, have twice outgrown their accommodations. To meet its requirements, the Society is erecting at Central Park West and 63d Street, a thoroughly modernized school building, next to which an appropriately dignified meeting place and society-house will later on be added. The very thoroughly equipped schoolhouse will enable the society, in greater measure even than in the past, to fulfil its cherished aim of having a model and experimental school, standing for the highest ideals of non-sectarian education and the most efficient pedagogical methods of realizing them. What distinguishes these from many other similar schools is their democratic organization and spirit: like the public schools, they educate children both of the well-to-do and of the poor, that is, an equal proportion of pay pupils and pupils admitted under a system of free scholarships endowed by the Society.

To give further effect to its conception of a religious society as a body of workers, bent upon learning by doing and promoting piety by service, the society opens to its members many other fields of education and philanthropic activity. Here the women of the society take a prominent part. Most of the philanthropies are affiliated under a general representative body known as the Women's Conference, through whose recent initiative and effort the Manhattan Trade School for Girls was established. Fortunate in drawing an unusual number of young men to its ranks, the Society has a strong Young Men's Union which contributes largely to the support of two neighborhood houses: the Hudson Guild on the West Side, of which Dr. John Lovejoy Elliott, one of Prof. Adler's associate lecturers, is the head worker; and the Down-Town Ethical Society, on the lower East Side. The Union also owns and supports a summer home on its farm of 70 acres at Mountainville, N. Y., where a farm school is held, and a summer holiday is given to groups of the boys and girls who belong to the Neighborhood clubs. The larger policies and relations of all the working bodies of the society are considered and shaped by a Council of Fifty, composed of representatives from all of them. One other event in the history of the society that calls for mention is the recent appointment of Prof. Adler to the newly created chair of political and social ethics at Columbia University. As the chair was endowed with a view to Prof. Adler's tenure of it at the instigation of some members of the well-known Committee of Fifteen appointed by the Chamber of Commerce to deal with the social evil in New York, of which committee Prof. Adler was an active member, this appointment is a remarkable public tribute to the large public place which the founder of the ethical movement has won for himself and for it.

Early in the history of the society, a number of young men were attracted to it, and, after a period of apprenticeship in New York, went forth to found societies in Chicago, Philadelphia, and St. Louis, and across the seas in London. These American societies are under the leadership respectively of William M. Salter, S. Burns Weston and Walter L. Sheldon; and, while loosely federated in a union, they maintain an individuality of their own, and have developed different forms of activity according to local needs and circumstances. They all hold Sunday exercises, which consist for the most part of music, readings, and an address. All admit to membership on a simple declaration of devotion to the ethical ends set up. All attach great importance to the moral and religious education of the young, and maintain well-organized Sunday schools and associations and clubs of young men and young women devoted to the same end and to various kinds of practical work. From the publishing and literary headquarters of the Ethical Union in Philadelphia (S. Burns Weston, 1305 Arch Street) is issued monthly 'Ethical Addresses,' containing the more important lectures of the leaders; and the 'International Journal of Ethics,' under a committee of ethical specialists in America and Europe with Mr. Weston as managing editor. The New York society publishes bi-monthly the 'Ethical Record,' a journal of practical ethics, edited by Percival Chubb, also one of Prof. Adler's associate lecturers. Among the literary products of the American societies are Prof. Adler's 'Creed and Deed,' 'Moral Instruction of Children,' and 'Life and Destiny'; Mr. Salter's 'Ethical Religion'; Mr. Sheldon's 'An Ethical Movement,' 'An Ethical Sunday School,' and 'Old Testament Bible Stories as a Basis for Ethical Instruction of the Young.'

That the movement initiated in America expressed no merely local phase of religious development is evident by its still more rapid spread in Europe. American influences led to the establishment in 1886 of the London Ethical Society with which Profs. Muirhead, Bosanquet, Bonar, and others, upon whom the ethical influence of Thomas Hill Green of Oxford had been profound, were identified; and under its auspices lectures were given at Toynbee Hall and elsewhere by many men at the universities and in public life who felt the importance of the new ethical propaganda, such as Seeley, Caird, Leslie Stephen, etc. About the same time Dr. Stanton Coit went over from New York to assume (*vice* Mr. Moncure D. Conway) the leadership of the congregation at South Place Chapel, then renamed the South Place Ethical Society, which, after a brief pastorate, he resigned to push the ethical cause in other ways. Under his energetic leadership, the ethical societies have multiplied rapidly in London and in the provinces, where also several of the Labor Churches have affiliated themselves with the ethical movement. A Union of Ethical Societies (14 or more), and a Moral Instruction League (to introduce systematic non-theological, moral instruction into all schools) are in vigorous activity; a weekly paper, 'Ethics,' has been maintained for several years; and there has been a considerable output of literature, including Dr. Coit's anthology, 'The Message of Man,' a 'Collection of Ethical Songs,' and, edited by him for the Society of Ethical Propagandists, a volume of essays by different writers, entitled 'Ethical Democracy'; Quilter's 'Upward and Onward,' a book for boys and girls; Sander's 'Reorganization of the People'; McCabe's 'Discipline in the Roman Church.' In London there is also an independent Ethical Religion Society, founded and led by Dr. Washington Sullivan. Ireland, likewise, has been reached, where there is an ethical society at Belfast. At Leicester, Eng., F. J. Gould, the leader of the Secularist Society there, has advanced the ethical instruction of the young by his 'Children's Books of Moral Lessons' (two series), and by his effective advocacy of the cause on the Leicester School Board, which he has forced to take an advanced position on the subject of moral instruction in the board schools.

The new movement was finding, meanwhile, favorable soil on the Continent. A centre of activity was established at Berlin, where Prof. Gizycki, Prof. William Foerster, and others identified themselves with the cause. Societies were in time established at Munich, Dresden, Danzig, Freyburg, Stuttgart, Breslau, Frankfort, Jena, Magdeburg, Strassburg, Ulm, Königsberg; and in Austria at Vienna, in Italy at Venice and Rome, in Switzerland at Zürich and Lausanne; and in France through the Union pour L'Action Morale (1891) which found spokesmen in M. Emil Desjardins (notably in his stirring brochure 'Le Devoir Present'), and in other well-known writers. Among the latest additions to the ethical societies is one at Tokyo in Japan. The German societies support a weekly paper, 'Ethische Kultur,' published at Berlin; and the Parisian society a monthly, entitled 'La Coöpération des Idées.'

The increasing activity in these European centres led to the establishment of an international organization with a central station at Zürich, and Prof. F. W. Foerster as secretary and organizer. Here in September 1896 an International Congress was held which issued a representative manifesto. It is largely colored by a continental sense of the urgency of applying ethical principles in the domain of social and political affairs. It announced its sympathy with the efforts of the populace to obtain a more human existence; but recognized as an evil hardly less serious than the material need of the poor, the moral need which exists among the wealthy, whose integrity is often deeply imperilled by the discords in which the defects of the present industrial system involve them. It demanded that the social conflict should be carried on within the lines prescribed by morality, in the interest of society as a whole, and with a view to the final establishment of social peace. It appealed to the ethical societies to provide the intellectual armor for this struggle, and to all their members to promote the progressive social movement by simplicity in the conduct of life and the display of an active social spirit. It declared (in view, doubtless, of prevailing scepticism and license) the pricelessness and indispensableness of the institution of pure monogamic marriage; demanded opportunity for the fullest development for women; advocated the improvement of the lot of female wage-earners in industrial establishments; and made a strong plea for the restoration of lost unity in the educational system by setting up a common ethical purpose as the aim of all culture. It declared for universal peace, and against militarism and the national egotism and jealousy which precipitate war. Finally, it urged upon all ethical societies not simply to concern themselves with these practical issues, but to devote their utmost energy to the building up of a new ideal of life in harmony with the demands of modern enlightenment. This manifesto represents most, but not all, of the leading interests of ethical societies. It expresses their almost universal interest in the social question, and their desire to bring theories, policies and measures of reform to the test of ethical principle; it expresses also their interest in promoting peace and an education animated and unified by an ethical purpose. It does not, however, lay stress upon the relation of the movement to modern liberalism, its frank acceptance of the spirit and results of modern science, and its repudiation of the supernatural, miraculous, and priestly elements in religion; nor does it voice the deeper religious seriousness and spirituality of the movement. By some of the leaders this latter is very strongly emphasized; and some of the ethical societies are primarily churches for inspiration and guidance in the difficult effort to lead the good life.

While the inception of the ethical movement was due to the insight and prevision of Felix Adler, and its first powerful impact due to his attractive eloquence and personal power, its rapid growth to international dimensions is clear evidence that it met a deep and widespread need. It was fitly born on American soil; for a new ethical religion and ethical church for America had been definitely prophesied and sketched by Emerson in his later essays on 'Worship' and 'The Sovereignty of Ethics.' He had said: "The progress of religion is steadily to its identity with morals. . . . It accuses us that pure ethics is not now formulated and concreted into a cultus, a fraternity with assemblings and holy days, with song and book, with brick and stone. . . . America shall introduce a pure religion. . . . There will be a new Church founded on moral science; at first cold and naked, a babe in a manger again, the algebra and mathematics of ethical law, the church of men to come, without shawms, or psaltery, or sackbut; but it will have heaven and earth for its beams and rafters, science for symbol and illustration; it will fast enough gather beauty, music, picture, poetry." The development of advanced Unitarianism through Channing and Parker had been in this direction. It had two practical outcomes — the Free Religious Association, which still holds annual sessions; and the Ethical Movement. As distinguished from the Free Religious Association, which expressed vaguely the libertarian tendencies of Emerson's thought, the Ethical Movement gave effect to the positive and constructive tendency which found clear utterance in his prophecy. Although this positive spirit was present in the religious society conducted in New York by Octavius B. Frothingham—who was wont to say, after he had retired and it had disbanded, that its legitimate successor was the Society for Ethical Culture—it was not until Felix Adler brought to the new movement at once an ethical outlook and philosophy learned chiefly in the school of Kant, an impassioned Hebraic sense of religion as righteousness of life, and a practical sense of the urgency and ethical import of the great impending moral issues in the social, industrial, and political world, that conditions existed for the full birth of the new ethical religion.

The most distinctive feature of this new phase of religious development was that it did not propose to add to the religions of the past, in the way in which these had multiplied, namely, on the basis of differences of speculative belief. Instead, it announced the basic importance and the priority of the ethical factor in religion. It approached religion, not from the credal, but from the practical moral standpoint; and it saw, in a common affirmation of this priority and supremacy of virtue and the good life, a ground of union for people of varying philosophical convictions, or none. Following Emerson, it asserted that character and conduct condition creed and thought; and that it is only by sowing a worthy character that men can reap a vital and meaningful creed. It contended that no certain and lasting basis of union can be found in anything so variable and personal as one's philosophical view of the world; and that no one should pledge his intellectual future by subscribing to-day to a creed which to-morrow he may outgrow. What a man thinks is the result of what he is,— the outcome, therefore, of his action, his experience, his effort and his love, far more than it is the outcome of his deliberate thought and accumulated knowledge. This position differed from that of the Comtian Positivists because theirs assumed a final, definite, and in some respects, very negative philosophy. The new movement allowed for the greatest individual differences in men's philosophical interpretation of life, save in the one tenet that all must acknowledge the sacred obligation imposed by man's moral nature to live the good life and to follow without swerving the dictates of duty according to the best light that is in each.

On the basis of this moral earnestness and this attitude of moral resolve men may safely and hopefully work backward into a philosophy and forward into a faith. Their philosophy and their theory of moral sanction may be what it will, theistic or pantheistic, materialistic or idealistic; it may or may not issue in a faith in immortality, conditional or absolute. This is a personal concern, and the statements on such matters frequently made by the leaders of ethical societies who differ much in their philosophies, are merely expressions of personal conviction, and not made as in any way committing the societies. This is to make a clear distinction between the private and the public factors of religious belief; and to find as the only possible basis for religious union, for those who would jealously guard their intellectual integrity, a moral aim by which any man should be ashamed not to be bound.

The ethical movement has been criticized, notably of late by Charles Booth, in his concluding volume reporting the life of the poor in London, as lacking in imaginative color and appeal, and therefore unlikely to spread among the masses of the people. Perhaps Emerson was right in emphasizing the austerities of the new religion in its early protestant phases. But at heart it is genial and passionately human. It has nothing sensationally novel to offer; it does not compete with picturesque claimants like Theosophy, Christian Science, Vedantism, etc., and it may be a fact that "plain goodness," "mere morality," "the beauty of holiness," will not yet draw many with their old-new evangel. And yet one finds among its adherents nothing less than a new type of the religious temperament, voicing a new imaginative sense of the hidden mysteries and wonders of the moral personality, the new unrevealed heights and depths of the moral life, the unrealized joyousness of devotion to duty and to service.

PERCIVAL CHUBB,
Editor the 'Ethical Record.'

Ethics (from Gr. ἠθικά, having to do with conduct, from ἦθος, character, lengthened form of ἔθος, custom, manners; *cf.* morals, from Latin, *mos, mores,* customs), that branch of the theory of conduct which is concerned with the formation and use of judgments of right and wrong, and with intellectual, emotional, and executive, or overt, phenomena, which are associated with such judgments, either as antecedents or consequents. As a branch of the theory of conduct, it is generically akin to the sciences of jurisprudence, politics and economics; but it is marked off from such sciences in that it considers the common subject-matter of human conduct from the standpoint of rightness and wrongness. Such terms as good and evil, the dutiful or obligatory, might be used in the definition as substitutes for the terms "right" and "wrong," but good and evil are somewhat too wide in scope, including, for instance, economic utilities, commodities and satisfactions; while duty is somewhat too narrow an idea, emphasizing the notion of control at the expense of the idea of the good and desirable. "Right" and "wrong" designate exactly those phases of good and evil to which the idea of the obligatory is also applicable. The terms moral philosophy, moral science, and morals have also been used to designate the same subject of inquiry.

In its historical development, ethics has been regarded as a branch of philosophy, as a science, and as an art — often as a composite of two or all of these in varying proportions. As a branch of philosophy, it is the business of ethics to investigate the nature and reality of certain conceptions in connection with fundamental theories of the universe. It is the theory of reality in its moral aspect. The term good is taken to denote or describe a property of ultimate and absolute being. As such, it is usually co-ordinated with two other fundamental properties of reality, the true and the beautiful; and the three philosophic disciplines are defined as ethics, logic, and æsthetics. Even when so much emphasis is not thrown upon the place of the good in the general scheme of the universe, ethics may still be regarded as a branch of philosophy, because concerned with the ideal, with what ought to be, or with what is absolutely desirable, as distinct from the actual, the existent, the phenomenal. From this point of view, ethics is regarded as *normative* in character, that is, concerned with establishing and justifying certain ultimate norms, standards, and rules of action.

In contrast with such functions, ethics as a science is concerned with collecting, describing, explaining and classifying the facts of experience in which judgments of right and wrong are actually embodied or to which they apply. It is subdivided into social, or sociological, ethics, and individual, or psychological, ethics. (*a*) The former deals with the habits, practices, ideas, beliefs, expectations, institutions, etc., actually found in history or in contemporary life, in different races, peoples, grades of culture, etc., which are outgrowths of judgments of the moral worth of actions or which operate as causes in developing such judgments. Up to the present, social ethics has been developed mainly in connection, (1) with discussion of the evolution of morality, either by itself or in connection with institutions of law and judicial procedure, or of religious cult and rite; or (2) with problems of contemporary social life, particularly with questions of philanthropy, penology, legislation, regarding divorce, the family and industrial reform — such as child-labor, etc. In both aspects it is closely connected with the science of sociology. It is sometimes called inductive, or in its second aspect, applied ethics. (*b*) Psychological ethics is concerned with tracing in the individual the origin and growth of the moral consciousness, that is, of judgments of right and wrong, feelings of obligation, emotions of remorse, shame, of desire for approbation; of the various habits of action which are in accord with the judgment of right, or the virtues; with the possibility and nature, from the standpoint of the psychical structure of the individual, of free, or voluntary, action. It gathers and organizes psychological data bearing upon the nature of intention, and motive; desire, effort and choice; judgments of approbation and disapprobation; emotions of sympathy, pity in relation to the impulse of self-preservation and the formation and reformation of habit in its effect upon character, etc. In other words, it treats behavior as an expression of certain psychical elements and groupings, or associations: psychological analysis.

Ethics as an art is concerned with discovering and formulating rules of acting in accordance with which men may attain their end. These rules may be considered as of the nature either of injunctions or commands, which prescribe as well as instruct; or as technical formulæ which indicate to the individual the best way of proceeding toward a desired result, thus not different in kind from rules of painting, or of carpentry. Which view is taken depends usually upon the kind of philosophy with which ethics as an art is associated. Ethics as an art may also be an outgrowth of either a general philosophy of conduct, or of a scientific analysis of it. Thus, from the philosophic point of view, a recent writer, Sorley, in the Dictionary of Philosophy and Psychology (Vol. I., p. 346, 1902), says of ethics: "It has to do not merely with actual conduct, but with right or good conduct, and accordingly with an ideal from which rules may be laid down for actual conduct." It is clear that the philosophical establishment of the ideal is considered to terminate in rules for its attainment. On the other hand, Jeremy Bentham in his 'Principles of Legislation' (1789), having before insisted that ethics is a science whose truths are to be discovered "only by investigations as severe as mathematical ones, and beyond all comparison more intricate and extensive," goes on to define ethics "as the art of directing men's actions to the production of the greatest possible quantity of happiness," and says it is the business of private ethics "*to instruct* each individual in what manner to govern his own conduct in the details of life." Thus as an art ethics may be grounded upon either a philosophy or a science.

As may readily be inferred from the above account, some of the most serious problems of ethics at present are concerned with defining and delimiting its own scope, basis and aims. From a purely abstract point of view, all three conceptions can exist harmoniously side by side. It is possible theoretically to regard certain topics as assigned to ethics as a branch of philosophy, others to its scientific phase, and others to the practical, or to ethics as an art. But no consensus as to these various possible assignments exists. Usually those who insist that ethics is a branch of philosophy deny that it can be anything else; they deny that any descriptive and explanatory account of *actual*, as distinct from ideal, conduct, deserves the name of ethics. What we have above treated as belonging to the science of ethics is by them treated as really a matter of history, sociology and psychology, not of ethics proper at all. Thus Green, 'Prolegomena to Ethics' (1883), begins by attempting to prove that a natural science of ethics is inherently impossible, because moral conduct by its nature implies an ideal that transcends actual conduct which alone can be made a matter of observation and experiment, and sets up an obligation which in its absoluteness transcends all the sanctions of experience. On the other hand, those who have occupied themselves with the scientific analysis of moral behavior and character, have usually denied the legitimacy of the philosophic aspect. Thus Bentham expressly regards all philosophical inquiries as doomed to result in sterility, in mere dogmatic personal assertions, or, as he calls them, "*ipse dixits*." A more recent writer, Leslie Stephen, 'Science of Ethics' (1882), without absolutely denying the possibility in the remote future of a metaphysics of conduct, says that the metaphysical view is entirely irrelevant to a scientific treatment. Along with this uncertainty as to the defining aim and characteristic methods of ethics, are naturally found a large number of subordinate and secondary controversies and divisions of opinion.

As a matter of fact, however, in every historical period there have been found in ethical theories some connection with general philosophic thought, and with the data of behavior exhibited in experience (or the scientific aspect) and with the further direction and conduct of life — the practical aspect. Historically, ethics has passed through three epochs: (1) the Græco-Roman; (2) the Patristic-Mediæval; (3) the Early Modern; terminating with say the French Revolution, and may now be regarded as having entered upon a fourth stage. In each period, a certain practical interest is uppermost in social life, and this interest serves to concentrate and direct attention toward certain relevant theoretic problems. An adequate account of ethical thought accordingly is possible only in connection with the larger civilization and culture of which it is a part. Brief characterizations of the main problem of each epoch in its wider social tendencies will serve, however, to point out (*a*) the philosophic, (*b*) the scientific, (*c*) the practical centre of ethics in each period.

The Græco-Roman period was characterized by the disintegration of local custom, tradition and institution, civil and religious, coincident with the spread of cosmopolitan learning and the formation of an inclusive political organization taking effect in both legislation and administration — Greek culture and the Roman empire. With the disintegration of the habits and modes of life which had previously defined the sphere of legitimate individual satisfaction, and which supplied the sanctions of the moral life, there was necessarily coincident an inquiry which attempted to establish through reflection adequate substitutes for the waning institutional modes of control. One of the results of modern historical science is the proof of the extent and stringency of the force of custom in early life. It is custom which defines the morally right and obligatory, and it is custom which enforces its own demands. In it are bound together morals, law, and religion, and all are bound into the very life of the people, emotional and intellectual, as well as practical. Where custom rules, moral theory is unnecessary and indeed impossible. In the 6th and 5th centuries before Christ, this régime of custom was irretrievably shaken in the Greek world, and with a twofold result upon morals. Many thought that all sanctions for morality had disappeared, or at least lost validity, and that pure individualism in thought and conduct — tempered at best only by some judicious regard to consequences — was the proper outcome. Others, prevented by what they regarded as the low moral standards of customary morality from coming to its defense were also shocked by the demoralization attendant upon ethical individualism, and set to work to discover a universal and unassailable basis for a higher type of ideal morality. In this conflict, ethical theory was born.

The Græco-Roman Period (6th century B.C. to 5th A.D.) — The controversy originated in a discussion as to whether morality exists by convention (νόμῳ), by arbitrary enactment (θέσει), or in reality, that is (in the terminology of the time), "by nature," (φύσει), or in the nature of things. Some of the Sophists taught that morality was a creature of the efforts of the rulers of a community, being a device on their part to keep others in subjection for the better indulgence of their own desires — much as many of the "free-thinkers" of the 18th century (in many respects the modern congeners of the Sophists) taught that religion was an invention of state-craft and priest-craft. Others taught that it was a product of social agreement or institution. Some of the nobler Sophists (like Protagoras, see the Platonic dialogue of the same name) interpreted this as praise of the state of civilization and culture as against the raw, crude state of nature; while others taught that it was merely a conventional means to personal satisfaction, and hence had no binding force when short-cuts to happiness were available. In the meantime, the actual moral discipline of the Greek city-state was much relaxed, partly because of the interminable dissensions of party strife; and partly because the religious beliefs which were the foundation of civic life were fast becoming incredible. Socrates (about 470 B.C.–399 B.C.) was apparently the first to undertake a positive and constructive analysis of moral ideas. He made the following contributions: (1) All things have to be considered with reference to their end, which indeed constitutes their real "nature"; the end of each thing is its good. Man must therefore have his own end, or good; this is real and inherent, not conventional nor the product of law. (2) To know is to grasp the essential, real being of a thing — its "nature," or end; "know thyself" is the essence of morality; it means that man must base his activity upon comprehension of the true end of his own being. All evil is really involuntary, based on ignorance, or misconception of man's true good. To be ignorant of the good is the one disgrace. If a man does not know it — and Socrates professed that he did not — he can at least devote himself seriously to inquiring, to the effort to learn. If not wise (a sophist) he can at least be a lover of wisdom (a philosopher). And until he attains knowledge, the individual will be loyal to the responsibilities of his own civic life.

The two conceptions of the good as somehow the fulfilment of man's true nature or reality, and as attainable only under conditions of rational insight are the bases of all later Greek thought. Opinions differed to what man's end is, and as to the character of true knowledge of it. The extreme division was between the Cynic school, the forerunner of the Stoics, founded by Antisthenes (about 444 B.C.–369 B.C.), and the Cyrenaic (the precursor of Epicureanism), founded by Aristippus (about 435 B.C.–360 B.C.). The former taught that virtue, manifested in temperance or self-control, is the one and only good, pleasure as an end being evil, and that it is known by pure reason. The latter taught that pleasure, known only in feeling (the sensation of a gentle and continuous change) is the good. The wise man of Socrates is he who knows this moderate and enduring pleasure and is not captured by sudden and violent passion. Both schools take a somewhat antagonistic attitude toward the state; the Cynic emphasizing the superiority of the sage to government and authority, well illustrated in the anecdotes of Diogenes and Alexander the Great; the Cyrenaic holding that the pleasures of friendship and social companionship of the congenial are superior to those of participation in public life. These schools thus set two of the fundamental problems of subsequent ethical theory, namely, the nature of the good, and the nature of knowledge of it; and supplied the framework of later schools of thought. Those who hold that pleasure is the good are termed Hedonists (Gr. ἡδονή, pleasure) those who held to its residence in the virtuous will Perfectionists, or (with certain qualifications added) Rigorists. Those who hold that it is known through reason are Intuitionalists, the other school, Sensationalists or Empiricists.

Plato (q.v.) (about 427 B.C.–347 B.C.) attempted a synthesis of the conceptions of the two schools just referred to, with a constructive programme of social, political and educational reform, and with a reinterpretation of earlier philosophic theories of the universe and of knowledge. His most characteristic doctrines are (1) the generalization of the Socratic conception of the good as constituting the true essence or nature of man. Under the influence of philosophic concepts derived from a variety of sources, Plato conceived man as essentially a microcosm; as the universe in miniature. He is composed of a certain arrangement of the elements of reality itself; hence he can be truly known only as the real nature of the universal reality which constitutes him is known; his good is ultimately one with the final cause or good of the universe. Thus Plato goes even farther than Socrates in asserting that morality is by nature — it is by the nature not only of man but of absolute reality itself, which is thus given an ethical or spiritual interpretation. Thus he grounded ethics on general philosophic conceptions and has been the model for all since who have distinctly conceived ethics to be a branch of philosophy. Moreover, since he regards the ultimate good of the universe as one with God and as the animating purpose in the creation of physical nature, he brings ethics into connection with religion, and with man's relations to the world about him. (2) Plato regarded the state in its true or ideal form as the best embodiment or expression of the essential nature of individual man; as indeed more truly man than any one individual. In its true organization, it reflects or images the constitution of the ultimate good. Thus Plato brings ethics back into connection with politics as the theory of ideal social organization. Practically, he delineates this state in outline (especially in his Republic, and, with greater attention to feasible detail in his Laws), and proposes in view of this ideal a specific reform of the existing order, instead of disregard of it as with Cynic and Cyrenaic. (3) He sets forth a scheme of the good as realizable in human nature, which endeavors to combine the one-sided extremes of mere pleasure, and mere virtue. He conceives the good to be the fulfilment of all the capacities, faculties or functions of human nature, the fulfilment of each power being accompanied with its own appropriate pleasure, and all being ordered and bound together in a harmonious whole by a law of measure or proportion which assigns to each its proper place; at the head, the pleasure of pure knowledge; at the bottom, the appetites; between, the pleasures of the nobler senses (sight and hearing), and of the higher impulses— ambition, honor, etc. The right functioning of each is virtue; its product is pleasure. The system of pleasures according to virtue is the good. Moreover, he specifies four cardinal virtues which result — wisdom, the knowledge of the good or organized whole; justice, the law of proportion or measure; courage, the assertion of the higher tendencies against the pleasures and pains arising from the contemplation or imagination of the lower; temperance, the law of subordination in accordance with which each lower function is restrained from usurping the place of the higher. Plato's system of ethics remains the standard of ethical theories of the "self-realization" type.

Aristotle (q.v.) (384 B.C.–322 B.C.) gave the philosophic considerations of Plato a more scientific and empirical turn — a contrast, however, which is often exaggerated. He protested against the identification by Plato of human end or good with that of the universe, and consequently attached less importance to knowledge in the form of philosophic insight, and more to practical insight or wisdom. But, in the main assuming the Platonic basis, he carried into detail the analysis of human faculties or functions involved in conduct, giving a careful analysis of desire, pleasure and pain, of the various modes of knowledge, of voluntary action, and making a remarkable analysis of the various forms of virtue and vice actually current. In a word, he emphasized in detail psychological and social aspects, merely sketched by Plato. On the social side, it had become obvious that the comprehensive scheme of reform entertained by Plato was impossible; and here, also, Aristotle is free to undertake a more empirical description and analysis of various forms of government and organization in their moral bases and bearings. When, in the 12th and 13th centuries A.D. the works of Aristotle were again made known to the European world, first through translations from the Arabic and then from the Greek, Aristotle's ethics became embodied in the official philosophy of the Roman Catholic Church, especially in the writings of St. Thomas Aquinas (1225–74), and found literary expression in the Divine Comedy of Dante. His ethical writings have more profoundly affected common speech and thought than those of any other writer, and to a large extent have become a part of the moral common-sense of civilized humanity.

The details of later ethical philosophy in Greece and Rome form an interesting part of the history of ethics, but, with one exception, supply no new idea of sufficient importance to need mention here. The exception is the Stoic conception of virtue as "living in accordance with nature," and the conception of the "law with nature" which grew out of this. This idea, under the form of *jus naturale*, was taken up into Roman jurisprudence, and became the ideal of a common moral law which underlies all differences of positive, municipal law, and which, accordingly, forms an ethical standard by which positive law can be tried, and its diversities reduced to a common denominator. It reappeared in the Middle Ages in the form of the natural law (as distinct from revealed or supernatural law), written on the "fleshly tablets of the heart," and was thus indirectly influential in forming the still current notion of *conscience* as a moral legislative force. It came out in continental ethical thought of the 17th and 18th centuries in the conception of moral law as something analogous to a system of mathematical axioms, definitions and demonstrations, discoverable by reason, and forming the framework of both individual and political ethics.

Patristic Mediæval Period (5th to 15th centuries A.D.)— The second period of ethical history is characterized by the subordination of ethics, as a branch of philosophy, to theology. The distinctive features contributed in this period to subsequent ethics are the emphasis laid upon ideas of law, authority, obligation or duty, and merit or demerit, namely, the good as religious salvation involving a knowledge and love of God as supreme perfection, possible only in the next world; and evil as sin, guilt also needing supernatural expiation. Because of the emphasis upon law and authority, moral ideas are largely assimilated to forensic and juridical conceptions. Most significant, however, for ethical theory is the transfer of theoretical interest from the conception of the good, the central idea of ancient ethics, to that of obligation. Not the natural end of man, but the duty of absolute submission of will to transcendent moral authority was the keynote. And even when ethics was freed from subservience to theology, it still remained easier for the modern mind to conceive of morality in terms of the nature and authority of duty than as the process of realizing the good. On the more concrete, empirical side, the great contribution of mediæval theory was in depicting the moral drama, the struggle of good and evil, as it goes on in the individual soul. The fact that this was fraught with significance for an endless future life made it a subject of anxious and minute attention; and here, too, even when the moral region was later marked off more or less definitely from the religious, modern thought owes its consciousness of the subtle perplexities, temptations and shades of moral effort and issue to mediæval rather than to ancient ethics.

Early Modern Period (The Reformation to the French Revolution).—The complexity and variety of moral theory and inquiry since the 15th century, as well as its relative nearness, make it difficult to secure the perspective necessary to its proper characterization. It is all more or less connected, however, with the struggle toward greater individual freedom, and with the problem of maintaining a stable associated and institutional life, on the basis of recognition of individuality — the democratic movement. In its earliest period, modern ethics was largely characterized by reaction against scholasticism; it was an effort to secure a basis for ethics free from subordination to theology and to mediæval philosophy, and the schoolmen's versions of Aristotle. Moreover so much of energy was expended in the practical effort to get freedom of thought, of political action, of religious creed, of commercial life, that moral theory turned largely upon detailed questions arising out of the practical struggle. This accounts to a considerable extent for the scattered, fragmentary condition of modern ethics as compared with the systematic character of either Greek or mediæval thought. Moreover, the very gaining of intellectual freedom of inquiry opened up countless fields of interest. Ethical problems sprang into existence at every turn; every new movement in industry, in politics, national and international, and in art, brought with it a new ethical problem. Social life was itself undergoing such rapid change, and in such tentative, uncertain ways, that each of these problems had to be attacked independently. The result is a critical, controversial and individualistic, rather than a constructive and systematized ethics — with the advantage, however, of remarkable richness in detail.

Continental ethics followed the prevailing philosophic method of rationalism: the attempt to build up a theory of conduct, individual and social, on the basis of pure reason, independent of revelation of ecclesiastic authority, or positive institutions. While the method was *a priori* in name, as matter of fact it drew largely upon the inheritance of generalized Roman law, attempting to harmonize and purify it in accordance with ideals of unity and comprehensiveness which were supposed to represent the demands of reason. Grotius (1583–1645) was the founder of this movement, and, in his *De Jure Belli et Pacis,* used the idea of law which is founded upon man's rational nature, which in turn is inherently social, to place international relations of comity, commerce and war upon a more humane and enlightened basis. His German successors, Puffendorf (1632–94), Leibnitz (1646–1716), Thomasius (1655–1728), Wolff (1679–1754), carried on with greater critical acumen and more adequate philosophic instruments, the same work, and finally developed a complete system of rights and duties (called *Naturrecht* after *Jus Naturale*) applicable to all spheres of private, domestic, civil, political and international life — a *code* of morals, positive in effect, but supposed all to be drawn deductively from rational first principles. Upon the whole, the influence of German ethical rationalism was conservative; the result in fundamentals was the justification of the existing social order, purged of inconsistencies and reformed of abuses in detail. French rationalism took a different turn. It attempted a synthesis of the more basal notions of the newly arisen physical science with psychological ideas borrowed from Locke and his English successors. It was rationalistic not so much in attempting to deduce an ethical system from the conceptions of reason, as in subjecting the existing order of belief and institutions to unsparing criticism as anti-scientific. In its extreme forms it seemed to demand an abrogation of existing institutions, the erection of the same *tabula rasa* in social matters, that Descartes had postulated in intellectual, and a creation, *de novo*, by sheer voluntary action, of a new social order, aiming at universal happiness. Reason gives an ideal of society in which all men shall be free and equal, and in which economic want and misery shall be abolished, and a widely diffused intelligence and wealth shall be instituted. Pessimistic to the extreme as regards the existing order, it was equally optimistic as to the possibilities of social organization, culminating in the conception of the infinitely progressive perfectibility of human nature; thus Helvetius, 1715–1771 (De l'esprit, 1758; De l'Homme, published 1773); Diderot (1713–1784); Condillac (1715–1780); D'Holbach (1723–1789), especially 'Système Social' (1773); Condorcet (1743–1794). While German ethics had emphasized the conception of natural law which is social in nature, French thought culminated in a deification of natural rights which are individual in their import and location. Certain characteristic features of not only the French Revolution but of the thought of American publicists in the latter half of the 18th century are directly traceable to this influence.

English ethical theory received its impetus from Hobbes (1588–1679). He begins with an analysis of the make-up of the individual, and resolves the latter into a bundle of egotistic impulses, all aiming at unrestricted satisfaction. He denies the existence of any inherent social tendency, or of anything "rational" in the individual save as deliberation may be involved in the individual's efforts after satisfaction. The social counterpart of this unlimited individualism is chaos, anarchy, conflict — the war of all against all. Hence the individual's quest for happiness is self-contradictory. It is possible of fruition only within the state of absolute power which prescribes to each individual the proper sphere of the exercise of his powers. The state is thus the author and sanction of all moral distinctions and obligations. The authority of this state with respect to individuals is absolute; since the source of moral law, it cannot be subject to anything beyond itself. There are thus three strains in Hobbes' teaching. The psychological, which teaches pure egotism and hedonism; the ethical, which makes the state the source of moral values and relations; the political, which makes its authority unlimited. Each strain evoked profound and instant reaction. John Locke (1632–1704) taught that the individual has a natural right to a life of personal security, possession of property and social activity, subject only to limits of the similar rights of others, and that the state comes into existence to protect and secure these rights by settling cases of dispute or aggression, and hence is null and void when it goes beyond this province, and encroaches upon individual rights. A succession of writers, notably Shaftesbury (1671–1713); Hutcheson (1694–1747); Butler (1692–1752); Adam Smith (1723–1790), undertook a re-analysis of human nature, and endeavored to justify the presence of disinterested, benevolent impulses, of tendencies to regard the welfare of others. Cudworth (1617–1688); More (1614–1687); Cumberland (1632–1718); Clarke (1675–1729); Price (1723–1791), took up the question of the origin of moral distinctions, and tried to show that they were based not in the state but in immutable laws of reason, or upon a science as abstract and certain as mathematics; or else were made known in intuition, etc. But during these inquiries, new problems came to light, and led to a rearrangement of forces. These problems were: (1) the relation of happiness — the expression of the self-seeking tendencies of man — to virtue, the expression of his benevolent tendencies; (2) the nature of the test or standard of right and wrong; (3) the nature of moral knowledge. The first problem led in Butler to the attempt to introduce "conscience" as a third and balancing authoritative factor in human nature; and in Smith and Hume (1711–1776) to a peculiarly rich and significant theory of sympathy as a central principle through which distinctively moral sentiments are generated and whose exercise is intimately bound up with individual happiness. The second and third problems taken together lead to the conflict of utilitarianism and intuitionalism, the former holding that conduciveness to the maximum of possible happiness is the standard of right, the basis of obligation, and the source of all moral rules; this conduciveness to be determined by actual experience; the latter holding that there are moral values, which are inherently and absolutely such, without reference to consequences. Each school has a theological and a non-theological variety. Among theological utilitarians are prominent Gay (1686–1761), and Paley (1743–1805); among the non-theological Jeremy Bentham (1748–1842) outranks all the others. Without adding much that is fundamentally new to the theoretical analysis, he makes an analysis of happiness in connection with a discussion of the various impulses (or motives as he termed them) of human nature the basis of a thorough-going scheme of judicial and penal reform. Through him utilitarianism became the most potent instrument of the first half of the 19th century of social reform; conduciveness to general and equally distributed happiness being the test by which all customs, traditions and institutions were tried — and by which most of them in their existent forms were condemned.

Recent Modern. (From the French Revolution.)—The last 20 years of the 18th century signalize a turning point in the history of thought. Bentham's and Kant's chief works are dated in this period. The French Revolution, carrying into effect the naturalistic rationalism and its optimistic faith in the possibilities of the individual, compelled a reconsideration of the intellectual premises from which it set forth. The problem of 19th century ethics was to get back from the individual to the social whole which includes him and within which he functions; but to do this in a way which should take due account of the deepened significance given to individual initiative and freedom — without, that is, a return to pure institutionalism, or to arbitrary external authority. The following schools or main tendencies are easily distinguishable:

(*a*) *English Liberalism.*— In Bentham, utilitarianism, as we have seen, became a programme of social reform. The attempt to stretch an individualistic hedonism which taught that the end of desire is always the agent's own pleasure into a theory which taught that the individual should always judge his motives and acts from the standpoint of their bearing upon the happiness of all beings, brought out all the weaknesses of the theory. James Mill (q.v.) (1773–1836) strove valiantly to overcome these weaknesses by a systematic use of the principle of association, in virtue of which individual states become indissolubly connected, through punishment or commerce, with the welfare of others — the theory of "enlightened selfishness," for which Hartley (1705–1757) had previously provided the psychological machinery. His son, John Stuart Mill (1806–1873) while extending the same idea, introduced into utilitarianism two innovations, which were seized upon by his intuitional opponents as virtual abandonments of the entire hedonistic position. These were that quality of pleasure is more important than quantity, and that the individual is naturally social and so instinctively judges his own welfare from the standpoint of society, instead of *vice versa*. J. S. Mill also severely criticised the other utilitarians for their neglect of the ideal elements in education, and for neglect of the culture element in historical development. Without abandoning the individualistic basis he was much influenced by schools (*b*) and (*c*) below.

From (*b*) came the influence of Coleridge (1772–1834); Maurice (1805–1872), and Sterling (1806–1843). Bain (1818—) belongs to the same empirical and utilitarian school. Sidgwick (1838–1900) in his 'Methods of Ethics' attempted a fusion of the utilitarian standard with an intuitional basis and method.

(*b*) German rationalism culminated in Kant (1724–1804), who reduced the function of moral reason in man to a single principle; the consciousness of the moral law as the sole and sufficing principle of action. Since the claims of this principle are opposed by those of self-love — the desire for personal happiness — the presence of moral reason in us takes the form of a "categorical imperative," or the demand that duty alone, without any influence from inclination, desire or affection, be the motive of conduct. Upon the consciousness of duty are built the ideas of freedom, God and immortality — that is, by moral action is opened to us a sphere of reasonable faith in transcendental realities which are shut to scientific and philosophic cognition. Kant brought rationalism to a turn much as Bentham had affected empiricism. Subsequent German thought attempted to overcome the formalism of Kant's bare reason making itself known only in a consciousness of obligation. Hegel (1770–1831) attempted a synthesis of the Kantian idealism with the ideas of Schiller, of Spinoza (especially through the medium of Goethe), and of the rising historical school founded by Savigny. He endeavored to show that the social order is itself an objective embodiment of will and reason, and that the regions of civil law, of family life, social and commercial intercourse and above all the state, constitute an ethical world (as real as the physical) from which the individual must take his cue. He anticipated in many particulars from the standpoint of a different method and terminology, doctrines of recent anthropology and social psychology. German moral influence has been felt in English thought chiefly through Coleridge, Carlyle (who was mainly affected by Kant's successor, Fichte, 1762–1814), and more recently, T. H. Green (1836–1882). The New England Transcendentalists were also affected by this school of thought, Ralph Waldo Emerson (q.v.) (1803–1882) giving a highly original version of it, blending it with factors of his own personality and with ideas drawn from Puritanism.

(*c*) In France, the reaction from the individualism of the Revolution was most marked. At the head of the reaction stands Comte (1798–1857), who attempted to build up a theory of ethics upon an organized social basis, similar in many respects to that of Hegel, but relying upon a systematization of sciences rather than upon philosophy, for method, his system accordingly being termed positivism. Comte sought to show how such an ethical-social science could replace metaphysics and theology, the latter in the form of a religion of humanity. He influenced G. H. Lewes and the latter's wife, George Eliot, and also John Stuart Mill.

(*d*) In the latter half of the 19th century the theory of evolution has been dominant in ethical as well as in other forms of philosophic and scientific thought. Herbert Spencer's application is the best known to English readers. It is, however, generally recognized that his fundamental ethical conceptions were worked out before he became an evolutionist, and that the attachments between his ethics and the theory of evolution are of a somewhat external character. Indeed, it is now clear that the further development of the science of ethics waits upon the more thorough clearing up of the evolutionary ideas themselves, and upon more complete application to biology, psychology and sociology (including anthropology and certain phases of the history of man) in order to supply the auxiliary sciences necessary for ethical science. Through the conception of evolution it is probable that ethics will be emancipated from the survival of the idea that it is an art whose business is to lay down rules. The practical aspect of the theory of ethics will necessarily remain (since it is theory of practice or conduct), but it will take the form of providing *methods* for analyzing and resolving concrete individual and social situations, rather than of furnishing injunctions and precepts. The coincidence of the evolutionary tendency with the growth of democracy will relieve ethics in its philosophic aspects from its dependence upon fixed values, ideals, standards and laws, and constitute ethics more and more a working method for the self-regulation of the individual and of society.

Every period of ethical theory has been associated, as we have seen, with some corresponding epoch of human development, having its own characteristic problem. Upon the whole, however, ethics has not as yet adequately outgrown the conditions of its origin, and the supposed necessity they imposed of finding something as fixed and unchanging as custom. Consequently, philosophic inquiry has been devoted to finding *the* good, *the* law of duty, etc.; that is, something unchanging, all inclusive. Even the empirical school, in its emphasis upon pleasure, has tried to find something free from conditions of development, something fixed in the sense of being everywhere and at all times the same single unchanging standard and end. Even Spencer distinguishes present ethical codes as merely relative, and anticipates a period in which evolution will reach its goal — a period in which an unchanging set of rules shall be uniformly binding. But as ethical writers become more habituated to evolutionary ideas, they will cease setting up ideals of a Utopian millennium, with only one end and law; and will devote themselves to studying the conditions and effects of the changing situations in which men actually live. Ethio'pia (Gr. αἴθω, to burn, and ὄψ, countenance), the biblical CUSH, in ancient geography, the name originally given by the Greeks to the southern parts of the known world. It is divided in the poems of Homer into eastern and western Ethiopia, and this distinction is repeated by Herodotus, and by the later Greek and Roman geographers. Homer gives the southern limit of Ethiopia as the northern boundary of the Southern Sea. Some ancient writers give the boundaries of the three Ethiopian kingdoms, Meroë, Aksum, and

Napata. Eastern Ethiopia appears to have included southern India, whose inhabitants were called Ethiopians from their color. There were also other Asiatic Ethiopians, an equestrian race, of a darker color than their neighbors, who wore crests made of the hides and manes of horses, and are supposed to have been a Mongolian tribe which had wandered into the steppes of Koordistan. The name Ethiopia was more usually and definitely applied to the country south of Libya and Egypt, between the Red Sea on the east and the desert of Sahara on the west, and embracing the modern regions of Nubia, Sennaar, Kordofan, and Abyssinia. In a still narrower sense, the designation was restricted to the province or kingdom of Meroë, which was also called the civilized Ethiopia. African Ethiopia, which is called in the Bible the land of Cush, embraced, according to Pliny, 45 distinct kingdoms; yet as neither the Greeks nor Romans ever penetrated beyond Napata, in lat. 19° N., we are indebted for most accounts of it to Greek imagination. Meroë, between the Nile and the Astaboras, formed the most powerful kingdom, and had a theocratic constitution. The other principal divisions were the Blemmyes, whose aspect was hideous; the Troglodytæ, who lived in caverns; the Macrobii, or long-lived men; the Ichthyophagi, or fish eaters; and the Creophagi, Chelonophagi, Elephantophagi, Struthophagi, and Ophiophagi, respectively the eaters of flesh, tortoises, elephants, ostriches, and serpents. Fable placed also in this region the race of pygmies. Some parts of Ethiopia were named from their productions; as the land of cinnamon, and of myrrh, and the Jews and Phœnicians went thither to obtain aromatics and ivory. The Ethiopian kings seem to have been chosen from among the priests, and the order of succession gave the crown to the nephew of the king, the son of his sister; and in default of an heir, an election was made. The people practised circumcison, and embalmed their dead in a manner similar to that of the Egyptians. They were of an intrepid, impetuous, and violent character, and yet are represented as loving and practising justice. Homer makes Jupiter visit them, and sit at their feasts. There were many Ethiopian queens named Candace, one of whom became subject to the Emperor Augustus. Under the Romans the population of Ethiopia became almost wholly Arabian, and so continued after the introduction of Christianity in the 4th century. When the followers of Mohammed overran the entire region some centuries later, the Arabic element gained complete predominance in it. During the Middle Ages the Christians and clergy of Abyssinia were designated as the Ethiopian Church.

Language and Literature.— Of the different dialects spoken in modern Abyssinia, the Amharic and the Tigré are the most remarkable. The former of these shows little affinity with the ancient language of the country, the Geez, or the Ethiopic properly so called, which since the beginning of the 14th century, when a dynastic change made the Amharic the language of the court, has ceased to be the vernacular, and is used only by people of education and learning, in religious and civil documents. This ancient language, which has its name from the inhabitants calling it *lesana geez,* that is, language of science, as it is also called language of books, is of Semitic origin, resembling in roots, structure, and grammatical forms, the ancient South Arabian dialect of the Himyarites, which since Mohammed has disappeared from the peninsula. This favors the hypothesis of some historians, who suppose the Ethiopians to have been a colony from Arabia. The alphabet also of the Geez greatly resembles that of the Himyarites, as found in their remaining inscriptions. It consists of 26 consonants and 7 vowels, which are small marks inseparably connected with the former, thus forming a peculiar syllabic mode of writing, analogous to the Devanagari and some other Indian alphabets. Few of these letters show a resemblance to the Phœnician alphabet, while 24 of them may be traced in the Arabic. There are no diacritical marks; the single words are separated by two dots; the accent is difficult; the mode of writing is from left to right, the reverse having been the practice before the introduction of Christianity into Abyssinia. In roots, and forms of expression and construction, the Geez is poorer than the Arabic. According to Gesenius, one third of all the roots can be traced distinctly in the Arabic, and many other words may be presumed to be of the same origin, while the roots of others can be found in the Hebrew, Syriac, or Chaldaic, some being native African, a few of Greek, scarcely any of Coptic derivation. The Geez has 10 conjugations, 8 of which answer to those of the Arabic, the 5th and the 6th being peculiar. A double infinitive is used substantively, this mood having both an absolute and constructive form. There is no participle. The dual is unknown both in verbs and nouns; the difference of masculine and feminine is observed throughout in the second and third persons. The relation of the genitive is expressed by an inflection, causing some changes in the terminations, or through the relative pronoun; the dative by prepositions; the comparative and superlative degrees by particles. The plural is formed by affixed syllables, *ân* in masculine, *ât* in feminine nouns, on the principle common to the Hebrew, Arabic, and Aramaic, or by changes in the radical letters, after the manner of the so-called broken plural in Arabic. In the formation of nouns the Geez most resembles the Hebrew, but it has superfluous final vowels, modified in certain cases, in which it is analogous to the Arabic in its nunnation. Beside a few fragments in inscriptions, there are no remnants of the ancient Ethiopian literature of a period preceding the introduction of Christianity under Constantine the Great, but of works composed since that time about 200 are known to European scholars. The Old Testament, translated from the Septuagint by unknown Christian writers in the 4th century, is extant in manuscripts in Europe, but only a part of it has been printed The Psalms were published in Ethiopic and Latin by Ludolf (Frankfort 1701), and in Ethiopic alone (London 1815). The version of the New Testament appeared at Rome in 1548, and in the London polyglot Bible. Of versions of apocryphal books, in which the Ethiopic is particularly rich, several have been published, as the 'Book of Enoch,' translated by Richard Laurence into English (2d edition, London 1833), and by Hoffmann into German (Jena 1838), in *Vatis,* translated by Laurence into Latin, and published in both languages (Oxford 1819). Geez in 1840 (London), and

Ascensio Isaiæ. The 'Didascalia, or Apostolical Constitution of the Abyssinian Church,' was published in Ethiopic and English by Platt (London 1834). The *Synaxar* contains lives of saints, martyrologies, and the hymns of the Ethiopian Church, in rude rhythmical form, every three or five lines often ending in the same consonant, which forms a kind of rhyme. The profane literature of the Ethiopian language is comparatively poor, consisting chiefly of chronicles, which appear to be of considerable interest, but have not yet been generally accessible. Of these the most remarkable are the 'Keber za Nageste,' containing the traditional and legendary history of the once mighty kingdom of Aksum, a copy of which was brought to Europe by Bruce, and a translation of it appended to his travels; and the 'Tarek Nagushti,' or chronicle of kings. In Europe the Ethiopian language was almost unknown until the time of Job Ludolf, who, being assisted by an excellent native scholar, Abbas Gregorius, made himself master of it, and published an admirable dictionary and grammar (2d improved and enlarged edition, Frankfort, 1702). Manuscripts written in the Ethiopian language are in possession of Abyssinian monks and in libraries in Europe. Their knowledge of music may be inferred from their musical notation which has been published. After a long interval the interest in this language and literature has been revived by the works of Platt, Laurence, Gesenius, Hupfeld, Hoffmann, Rödiger, Ewald, and others, as well as by the contributions of Isenberg, Blumberg, and D'Abbadie. E'thiops Mineral, a name formerly given by chemists to the black sulphide of mercury, prepared by rubbing mercury and sulphur together, either hot or cold. *Æthiops martis,* or ethiops of iron, was the black oxide got by exposing iron-filings and water to the air. Vegetable ethiops is the plant bladder-wrack, heated until it becomes black, a remedy for scrofula.

Eth'moid Bone, The (so called from *ēthmos,* «a sieve»), is one of the eight bones which collectively form the cranial box. It is of a somewhat cubical form, and enters into the formation of the cranium, the orbits, and the nasal fossæ. Its upper surface is perforated by a number of small openings (whence its name). See NOSE.

Ethnog'raphy, a branch of ethnology, the vast science which treats of mankind as a whole, their origin and their development in language, art, religion, and political ideas, from barbarism into civilization. The German scientists class ethnology as a science standing midway between natural history and philosophy. As natural history, in the ordinary sense of the term, is a classification and description of the lower animals, ethnology may fairly be considered as a classification of the various families of the human race, based on the observation of their physical characters, and geographical distribution. From the earliest records and monuments of mankind we find traces of various types of humanity. The statues and paintings of ancient Egypt represent several racial types including the negro, the Berber, and the Asiatic. In the first book of Moses, mankind are divided according to their descent from one of the three sons of Noah, Shem's progeny occupying Western Asia, while to the posterity of Ham and Japhet fell North Africa, and Southern Europe, respectively. Some recognition of the superficial physical differences observable in variously distributed races may also be found in Greek and Roman writers. In the Middle Ages little progress was made in ethnography. The discovery of America, with its revelation of new human types, seems to have given the first genuine stimulus to this study, and the word ethnography was first used in a book published at Nuremberg in 1791, and entitled 'An Ethnographical Picture Gallery.' In his great work, 'Systema Naturæ,' Linnæus classes mankind (*Homo sapiens*) together with the apes under the order of *Primates,* and divides them into four groups, as American, European, Asiatic, and African. Buffon in his 'Variétés dans l'espèce humaine' distinguishes the races according to their geographical distribution, though he makes some reference to physical variations. Blumenbach was the first to classify the races of men according to the shape of their skull. The Caucasian, whose skull was symmetrical, he set, as the normal type, midway between the Mongolian with the square skull, and the negro with his prognathous skull, while the American was ranged between the Mongolian and the Caucasian, and the Malayan between the Caucasian and the negro. In each of these types he distinguished and recognized as important the character of the hair, the setting of the eyes, and the form of the mouth.

The modern science of ethnography dates from the year 1829 when Milne-Edwards wrote to Thierry, with the result that the Société Ethnologique was founded. The founding of an ethnographic museum was suggested by Jomard in 1843, and built some years later in Paris. Since that time the study has been thoroughly systematized all over the world. While of all ethnographical classifications the most obvious is the enumeration of the white, yellow, red, and black-skinned races, as together making up mankind, this is clearly insufficient, as it would be likely to confound widely different types. Many attempts at a more scientific classification have been made. Oscar Pechsel recognized seven races of men: (1) the Australian; (2) the Papuan, including the Melanesian, the Negrito, etc.; (3) the Mongolian, including the Polynesian, the Malay, the Eskimo, and the American Indian; (4) the Dravidian (southern India and Ceylon); (5) the Hottentot and Bushman; (6) the negro; (7) the Mediterranean races, or Caucasian, which include the Hamitic, Semitic, and Indo-European.

It will be seen that these divisions are based upon other considerations than those of physical character, for it is merely because of their geographical proximity that the Hamitic, which includes the inhabitants of North Africa, can be placed in one category with the Caucasian. Among the most recent systems of ethnographical classification is that of Haeckel who has divided the human family into races in accordance with the variations of a single physical character, that namely of the hair. According to his authority there are two main species and four sub-species of hair found among mankind, who may be broadly separated into the woolly-haired (Ulotriches), and the straight-haired (Lissotriches). The woolly-haired consist (1) of the crested-haired (Lophocomi) subdivision, represented by the Hottentot, and the Papuan; and (2) of the fleecy-haired (Eriocomi) which includes the negro and the Kaffir. The straight-haired are sub-divided into the streaming-haired, and the curly-haired. To the former belong the Australian, the Arctic dwellers, the American Indian, Malay, and Mongolian; to the latter the Dravidian, the Mediterranean races, and the Nubian.

Ethnology, that branch of the science of anthropology which treats of the races of mankind and seeks to explain their origin and development.

Anthropology is the science which treats of man in relation to himself, to other men and to all nature. It is subdivided into several branches, each of which treats of some special phase of man's natural history. There is a difference in the meaning given by students to the names employed to designate the divisions of the study of man. Ethnology, ethnography, and anthropology have been to some extent interchangeable terms. Each of these branches of knowledge has a special meaning given it in different countries. However, there is becoming a more general acceptance of a definite meaning for these topics. The comprehensive term anthropology is recognized in its general sense to include all others (Keane, Tylor, Mason). The meaning herein given to Ethnology is widely recognized (Keene, Brinton.) The use of the term anthropology, to designate societies for the study of man and for sections in national scientific bodies on both sides of the Atlantic, indicates a general tendency to accept the proper meaning of the word.

Etnnology differs from ethnography, which deals chiefly with the collection of facts regarding the families, tribes and races of mankind, in seeking to explain the significance of the information obtained. Ethnography (from *ἔθνος*, a people, *γράφειν*, to write) is a writing about, a description of, peoples. Ethnology (from *ἔσνος* a people, *λόγος*, a discourse), attempts to interpret the facts gathered, to explain the causes for the conditions and the relationships of different peoples. Ethnography and ethnology occupy a relation to each other somewhat akin to that of geography and geology. One deals chiefly with existing facts; the other attempts to interpret the history which brought them forth.

Broca says ethnography studies peoples, ethnology races. The following seems a convenient scheme for grouping the branches of anthropology. Substantially it is as follows: Archæology, Biology, Psychology, Ethnology, Ethnography, Philology, Technology, Sociology, and Religion (Mason).

The unity of the race is now generally accepted. From the researches of the physiologist, the anatomist, the philologist and the psychologist we obtain the same testimony as to the specific unity of our race. The place of origin or centre of dispersal is not fixed. From the studies of eminent specialists, it would seem that the land about the shores of the Mediterranean, or the region farther eastward toward India, may claim to be the home of primitive man. About the Mediterranean they settled down like frogs about a pond (Plato).

For classification, mankind is divided into groups. On account of their distribution, these are sometimes named for geographical divisions. They are also distinguished as families, clans, tribes, nations, peoples and races. In the naming of the latter, family relationships form a prominent factor. It is with both of these lines of classification and the distribution of those discussed under them that ethnology has to do.

In these efforts at classification, different schemes have been tried. It is generally accepted that there are two groups of elements of characterization, which are sometimes called criteria. These are physical elements and psychical elements.

The principal physical elements are the bones, the shape of the skull, the facial angle, the color of the skin, color, shape and texture of the hair. Of these, color, probably because the most conspicuous feature, was the first to be considered and formed the basis of all the early classifications. The craniological school founded by the elder Retzius (1796–1860), made the shape of the head the basis of classification, and introduced exact methods into this branch of the subject. This was based on the relative length and breadth of the skull, and accordingly mankind was divided into long-skulled, and short, broad-skulled races. Later developments in craniology introduced a third class, representing a mean between the other two. Craniology alone cannot be depended upon to supply sufficient or trustworthy materials for the proper classification of mankind. Nevertheless it has thrown much light upon the subject. Of late years the color, shape and texture of the hair have steadily risen in the estimation of naturalists as a racial test. The hair is now regarded as the most constant of all the physical features, and has been made the foundation of their groupings by some of the most eminent anthropologists.

The other physical ethnical elements are of little value separately, but are often useful aids in combination with others. Such are stature; the shape, color and position of the eye; the size and form of the brain; the shape of the nose and mouth; the superciliary and zygomatic arches, and all such other elements as collectively constitute the broad, flat features of the lower, the oval and regular faces of the higher races.

The psychical elements are less conspicuous, and have but recently been taken into account in classification. It has been said that "Love and hunger rule the world." The former relates to the perpetuation of kind, the latter to self preservation. Around these two may be grouped the other factors of this class. The following are the principal psychical elements:

(1) Preservative instinct, food, clothing, shelter; (2) Perpetuating instinct; (3) Language; (4) Religion; (5) Government; (6) The Arts.

Food, clothing and shelter are the imperative needs of the human species at all ages and under all conditions. Among the prominent topics considered under the sexual impulse are the

RACES OF MANKIND

BUSHMAN: 1. Bushman (after *Fritsch*).—2. Namaque woman (after photograph, *Fabri*). NEGROES: 3. Loango woman (after Doctor *von Falkenstein*).—4. Man from Darfur (after photograph, *Hagenbeck*). NEGRITOS: 5. Man from the New Hebrides (after *Godeffroy*). 6. Woman from Tasmania (from a photograph, *von Bulow*). BLACK-HAIRED RACES: 7. Italian woman (from life). 8. Italian (from life). AUSTRALOIDS: 9. Man from Southwestern Australia (after photograph, *von Bulow*).—10. Nubian woman (after photograph, *Hagenbeck*). BLOND RACES: 11. Danish Girl (from a photograph).—12. South Russian (from a photograph). POLYNESIANS. 13. Girl from the Tonga Islands (after *Godeffroy*).—14. Dyak from Borneo (after *Dammann*). MONGOLOIDS: A. 15. Tarantsha-Mongol (after *Prschewalskij*).—16. Kalkas-Mongol woman (after *Prschewalskij*).—B. 17. Chinaman (after portrait, Museum of Ethnology, Berlin).—18. Yakut woman from the Cheta (after *Middendorf*). C. 19. North Am. Indian (after photo).—20. South Am. Indian (after *Kohde*). ESKIMO: 21. Koriak woman (from "Peoples of Russia").—22. Eskimo from Greenland (after photograph, *Hagenbeck*).

position of woman, the marriage relation and the line of descent. Language is the chief of the psychical elements. Some perhaps, with Horatio Hale, would make it the sole test of race. The power of religion, both as a constructive and dispersive force, is the repeated testimony of history. The organization and administration of government, whether in its primitive form or in the more enlightened stage, is of deepest interest. The arts of life find their origin in the rude homes of early man, and have steadily been influential in all human progress. For these have lives been lost, tribes been destroyed, nations been formed, battles been won. They have been the motive power in every effort, the impulse behind every forward movement of mankind from the earliest days to now.

There have been so many changes in this world of ours and so many mixtures of ancestral strains that it is impossible to determine certainly to which race certain peoples belong. After successive efforts by able students to classify mankind upon this or that character or group of characters, the tendency now seems to be to return to the earlier classification. To recur to the three greater subdivisions — white, black and yellow; or, Caucasian, Negro, Mongolian.

With all the data gathered and the characters used in succeeding classifications, the original color plan in a general way is as good as we know. Popularly, too, this seems to have struck the fancy. Without thought we speak of a person as white, black or red, as he is a Caucasian, Negro or an American Indian.

Dall divides man into three groups: white, black, and yellow. Flower and Lydekker also assign all representatives of mankind to three primary divisions. The status of the American aborigines is left unsettled. Keane gives to these a place among the races, making four. Linnæus in his day adopted four primary divisions. He, however, recognized man as a distinct genus, *homo*, having four species: *Homospæthiopicus*, *Homospmongolicus*, *Homospamericanus*, *Homospcaucasicus*. Gerland divides mankind into six races, separating the Dravidians from the other groups. To-day man is considered a single species, having several varieties or races. Blumenbach gives five groups, classified according to the color of the skin. Prof. Huxley also designated five groups along somewhat similar lines. Morton used the skull as a basis of

GENERAL ETHNOGRAPHIC SCHEME.

Race	Traits	Branches	Stocks	Groups or Peoples
European	Color white Hair wavy Nose narrow	I South Mediterranean	1. Hamitic	1. Libyan 2. Egyptian 3. East African
			2. Semitic	1. Arabian 2. Abyssinian 3. Chaldæan
		II North Mediterranean	1. Euskaric	Euskarian
			2. Aryac	Indo-Germanic or Celtindic peoples
			3. Caucasic	Peoples of the Caucasus
African or Negro	Color black or dark Hair frizzly Nose broad	I Negrillo	1. Central African 2. South African	Dwarfs of the Congo Bushmen, Hottentots
		II Negro	1. Nilotic 2. Sudanese 3. Senegambian 4. Guinean	Nubian
		III Negroid	1. Bantu	Kaffirs and Congo tribes
Asiatic or Mongolian	Color yellow or olive Hair straight Nose medium	I Sinitic	1. Chinese 2. Tibetan 3. Indo-Chinese	Chinese Natives of Tibet Burmese, Siamese
		II Sibiric	1. Tungusic 2. Mongolic 3. Tartaric 4. Finnic 5. Arctic 6. Japanic	Manchus, Tungus Mongols, Kalmucks Turks, Cossacks Finns, Magyars Chukchis, Ainos Japanese, Koreans
American	Color coppery Hair straight or wavy Nose medium	I Northern	1. Arctic 2. Atlantic 3. Pacific	Eskimos Tinneh, Algonkins, Iroquois Chinooks, Kolosh, etc.
		II Central	1. Mexican 2. Isthmian	Nahuas, Tarascos Mayas, Chapanecs
		III Southern	1. Atlantic 2. Pacific	Caribs, Arawaks, Tupis Chibehas, Quichuas
Oceanic	Color dark Hair wavy or frizzly Nose medium or narrow	I Negritic	1. Negrito 2. Papuan 3. Melanesian	Mincopies, Aetas New Guineans Feejeeans, etc.
		II Malayic	1. Malayan 2. Polynesian	Malays, Tagalas Pacific Islanders
		III Australic	1. Australian 2. Dravidian	Australians Dravidas, Mundas

classification; Haeckel and Broca the hair; and Hale language.

To one who carefully goes over the different schemes of classifying man, it is apparent that none is wholly satisfactory. Each in some direction overlaps some other. It is by taking all these race criteria so far as they are of value that the most reliable conclusions may be drawn as to the proper classification of mankind. No one set of standards will properly answer. That classification will be most satisfactory which obtains the most help from all the elements. All that we can aim to do is to group under some general and loose fitting subdivisions those members of the species which display the greatest number of similarities. (Brinton.) Perhaps it will be as satisfactory to follow the plan of Linnæus and classify the races of men according to geographical areas. Under such a plan we speak of the European race, which in ancient times was confined to Europe and adjacent parts of Asia and Africa; the African race, whose natural home is Africa; the Asiatic race, which is chiefly confined to Asia; the American race, composed of those occupying the western continent before its occupation by Europeans; and, the Oceanic or Australian race, comprising the tribes of Polynesia, Australia and the many groups of islands sometimes included in Oceanica. We can use Blumenbach's scheme of dividing them according to the color of the skin. Under it, they are grouped as follows:

1, Caucasian, or white; 2, Ethiopian, or black; 3, Mongolian, or yellow; 4, American, or red; 5, Malay, or brown. Dr. D. G. Brinton enumerated five races of mankind. Their chief characteristics may be summed up substantially as follows: I. The European Race — Traits — Color white, hair wavy, nose narrow, jaws straight, skull variable, languages inflectional, religions ideal. II. The African, or Negro Race — Traits — Color black, hair woolly, nose flat, jaws protruding, skull long, language agglutinative, religions material. III. The Asiatic, or Mongolian Race.— Traits — Color yellowish or brownish, hair straight, nose flat or medium, jaws straight, skull broad and high, languages isolating or agglutinative, religions material. IV. The American Race — Traits — Color coppery, hair straight, nose narrow, jaws straight, skull variable, language incorporating, religions ideal. V. The Oceanic Race — Traits — Color dark, hair lank or wavy, languages agglutinative.

Classified in this manner, the human species presents the subdivisions shown in the scheme on the opposite page.

Of the South Mediterranean branch of the European race there are given two divisions, the Hamitic and the Semitic. The former is divided into three groups, the Libyan, Egyptian and East African. The Libyan group extends over northern Africa from the Atlantic Ocean to the Nile. Some of these tribes are very dark and have been termed "Black Caucasians." Nevertheless, except for color, they are fine representatives of the white race. The Egyptian group is represented by the ancient Egyptians and their descendants, the modern Fellah of the Nile valley and the Copts. These two groups of this branch of the European race have been potent factors in the world's history. The development of the earliest seats of culture, the organization of government, and the establishment of high degrees of civilization have been the work of their representatives. On the contrary the East African group is represented by a number of tribes who are chiefly nomadic and occupy the territory south of the Egyptian group and extending from the Nile to the Indian Ocean. They include the Gallis, Somalis and Agaas.

The Semitic stocks are made up of three groups — the Arabian, Abyssinian and Chaldæan. The most prominent of the first group are the Arabians; the existing tribes best known are the Ishmaelites and Bedouin. They have occupied at different times parts of the Arabian peninsula and now practically cover it all.

The Abyssinian group is supposed to have originated in the region last mentioned and to have been dispersed over Abyssinia and adjacent parts of Africa. They have become mixed with adjoining tribes and a corrupt form of Christianity exists among them. The Abyssinians, Tigre and Amhara are prominent nations. The former is best known.

The third group of Semitic peoples has been called the Chaldæan. This includes the Syrians, Israelites, Samaritans, Babylonians and Jews. They also originated in Arabia and spread out into other lands. The Jew has become worldwide in his dispersal. From these peoples great nations were developed and from them two great religious leaders, Jesus Christ and Mohammed, have sprung.

The North Mediterranean branch is divided into three divisions. They are the Euskaric, Aryac and Caucasic stocks. The only surviving remnant of the Euskaric stock is the Basques of Spain. That they formerly were more widely distributed is generally believed. Their relationship with other peoples is not satisfactorily determined. The most extended and most important of these race stocks is the Aryac. The origin of the Aryans has been a fruitful theme of discussion in recent years. While there is still a difference of opinion on this subject, the majority of writers have accepted the theory of their European origin. The Aryac or Indo-Germanic stock is divided by Brinton into eight groups: Celtic, Italic, Illyric, Hellenic, Lettic, Teutonic, Slavonic and Indo-Iranic groups.

The Lettic or Lithuanian peoples, while comparatively inconspicuous, are in some respects the most interesting of their fellows. They are thought by some students to be the remnant of the original stock and that which most resembles it. They are located along the Baltic Sea in Prussia and Russia.

The Indo-Iranic group is of special interest because it has the farthest eastern range and for the reason that it is nearest the region which those who believe in the Asiatic origin of the race think was its primitive home. The term Iranic is derived from the plateau of Iran, which has been thought by some to be the area of dispersal of the race. The group divides into two divisions, the Iranic, whose old representatives were the Bactrians and Persians. To-day it includes the modern Persians, the Parsees, generally known as fire-worshippers, and the tribes of Beluchistan, Afghanistan and neighboring regions. The Indic branch comprises the peoples occupying India. The most prominent of these are the Hindus, Rajpoots and Djats. The typical Brahmins probably are the best representatives of the stock.

The Teutonic group includes the Germans, English, Norwegians, Swedes and Danes, and their ancestors, the Goths, Vandals, Angles, Saxons, Norsemen. These independent, aggressive, progressive races have been conspicuous in the history of the past and the activities of the present. They have spread throughout the world as missionaries of business, education or religion. They are the forces which operate in all progressive government and are destined to sway the world.

East of these is the Slavonic group. It is represented to-day by the Russians, Poles, Czechs, Bulgarians, and other tribes of the Danube region. Of their ancestors known in history are the Scythians and Massagetæ. The Slavonic tribes to the east, in one direction, came in contact with the Indo-Iranians and, in another, with some of the branches of the Mongolians. Within comparatively recent times some of them have made remarkable progress in civilization. Russia now ranks as one of the great world powers.

The Hellenic group comprised the ancient Greeks and their relatives. They occupied at an early date the peninsulas of Asia Minor, Greece, the southern part of Italy and contiguous territory. The progress of Greek culture is familiar. Greek language, literature and art form the basis of education everywhere. Their dominion was one of the world's greatest confederacies. Overthrown by the Romans and subsequently by the Mohammedans, they were for generations hidden from the view of the progressive world. The Illyric stock is situated near the Greeks in Turkey. It is represented by the Albanians. The Italic stock covered most of the Italian peninsula. The Umbrians, Etruscans, Oscans and Latins were the principal older representatives. They developed the Roman empire and in the organization and conduct of government and the framing of laws they achieved a front place in the history of the world.

The Celtic group, originally spread over western Europe, has largely disappeared. Certain parts of the British Isles and the north of France contain the surviving members. These are the Irish, Welsh, Scotch, Manx and the people of Brittany.

The Caucasic stock is represented by four groups: Lesghic, Circassic, Kistic and Georgic. They occupy the Caucasus Mountain region.

The African race occupies Africa south of the Sahara desert and of the Nile valley. It is classified in three groups: the Negrillos, Negroes and Negroids. Under Negrillos (little Negroes) are grouped the Akkas and other pygmies of the interior region, and the small-sized Bushmen and Hottentots farther south. The characters of some of these tribes are faithfully preserved in figures upon the Egyptian monuments. The most striking of these physical features is the peculiar growth and development about the pelvic region. The clicks of the Hottentot and Bushman languages find no counterpart in any other tongue. The Negroes are confined chiefly to western and central Africa, ranging east into Nubia. They comprise four subdivisions: the Nilotic, Sudanese, Senegambian and Guinean. The first is confined to the upper Nile valley. The Sudanese group is represented by tribes in Sudan and westward. The western coast south of the Senegal River is the territory of the Senegambians. Farther south toward the Niger River are the tribes of the Guinea group. This region was the chief source of the slave trade. The descendants of the Guinea negroes found throughout the United States are living witnesses of the slavery which existed there but a generation ago.

The Negroids approach the Negroes, but are in some ways quite different from them. Their color is brown rather than black; their hair is "kinky" but not woolly; the nose is straight and not short and flat. They are of two groups — the Nubian and Bantu. The former are found in Nubia and the upper Nile valley. The latter occupies practically all of southern Africa except the region of the Hottentots and Bushmen. Among the better known tribes are the Kaffirs, Bechuanas and Zulus. The African race occupies a low stage in culture. It has developed in the restricted area south of the Sahara basin. Probably it reached its typical development in the Niger valley.

The Asian, or Mongolian race is made up of two divisions — the Sinitic and Sibiric. The Sinitic branch includes the Chinese, Tibetans and the inhabitants of Anam, Siam, Burma and Cochin China. The Chinese have occupied their territory from quite early times. They have developed a peculiar civilization and in some particulars reached quite a high stage of culture. While there is considerable difference of opinion whether the arts of ancient China developed there or were acquired from the Aryans to the westward, it seems probable that in a great measure at least, they were indigenous.

The Sibiric branch of this race is largely located north of the mountains of Central Asia, ranging with the Arctic Circle from the Pacific to the Atlantic Ocean. The six groups are the Tungusic, reaching from northern China toward the Arctic Ocean and to Kamchatka. The Mongolic occupying the vast highlands west of Manchuria. Genghis-Khan and later Tamerlane established two of the wide extended Mongol empires. The Tartaric, another highland group, has spread from Turkestan in several directions. The Turk is the most conspicuous representative, though much mixed with other races. The Finnic is a group of Mongols occupying northern Europe. It is represented there by the Finns and Lapps and farther south by the Magyars. From there it extends east to the Volga River. The rude tribes fringing the Arctic Ocean in eastern Siberia and reaching to the Pacific are grouped under the name Arctic. The Chukchis and Kamchatkans are of their number. The Japanese and Koreans constitute the Japanese group. The Japanese are the most progressive and advanced of the Asiatic race.

The Oceanic race may be divided into three stocks — Negritic, Malayic and Australic. It occupies Australia, the islands of the South Pacific and Indian oceans, and the adjacent shores of Asia. In their migrations, whether along the shores or over the seas, they have so intermingled that their relationships are puzzling. The Negritic stock is represented by the Negritos, including such small peoples as the Mincopies of the Andaman Islands, the Papuans of New Guinea and other islands, and the Melanesians. The Malayic stock is the most conspicuous and energetic of the ocean peoples. Its representatives are found extending almost two thirds around the world, reaching from Easter Island to Madagascar. The most typical Malays are found in Malacca, Sumatra and Java, while others less marked extend from the Celebes to the Philippines. The Malays farther to the eastward are often called Polynesians. From their traditions it has been possible to obtain a fairly good idea of their successive migrations and of the comparative time of the settlement of the different island groups. They extend from New Guinea to New Zealand, Easter and the Sandwich islands. The Australic stock includes the different tribes of Australia, the extinct Tasmanians, and, according to some authorities, the primitive peoples of the peninsula of Hindustan. The Australians are very low in culture, nomadic, lacking government and wear little or no clothing. "The life of these savages proves to be of undeveloped type, alike in arts and institutions, so much so, that the distinction of being the lowest of normal tribes may be claimed for them."—(E. B. Tylor.)

The American race includes those peoples occupying the western continent at the time of its discovery by white men. For the purpose of study they may be divided into seven groups: Arctic, North Atlantic, North Pacific, Mexican, Inter-Isthmian, South Atlantic, South Pacific.

The Arctic group includes the Eskimo and Aleutian peoples. They occupy the shores of the oceans in Arctic America, and extend from Labrador to Greenland. In the North Atlantic group are some Indians of wide range. The Athabascans extend from the valleys of the Yukon and lower Mackenzie, to Arizona, while farther to the southward reaching into Mexico, the warlike Apaches are of this group. The Algonkins ranged from Newfoundland to the Rocky Mountains and from the Churchill River valley and Hudson Bay southward throughout the Ohio and Mississippi valleys to the Tennessee River. These included most of the Indians encountered by the early settlers. Their names are more or less familiar to us from history. The intelligent Iroquois, the formidable Dakotas (Sioux), the southern Indians, some of whom built mounds within historic times, and the tribes of the interior plains also belong to this division. The North Pacific group includes a number of tribes west of the Rocky Mountains, many of which are small and represent distinct linguistic stocks. Several of these tribes have the head artificially deformed. These include the Flatheads and Nez Percés (Pierced Noses). The Cliff-dwellers and Pueblo tribes of the arid regions of the southwestern United States are placed here. The Mexican group is notable because of the state of civilization attained by the Aztecs, its best known tribe. The organization developed, government established, education acquired, buildings constructed and arts pursued were unequaled by any tribe of the American race. The Mayas were the most important tribe of the Inter-Isthmian group. They were builders of note, elaborate decorators of stone, and mural artists. The South Atlantic group occupied the Atlantic coast of South America. They were chiefly wandering tribes without settled habitations. The Quichuas of Peru are the best known tribe of the South Pacific group. They attained higher civilization than any other South American tribe. They developed agriculture, domesticated animals, constructed large buildings of stone, were expert workers in metals, and devised a method of record keeping by means of strings and knots called quippus. See Keane, 'Ethnology'; Brinton, 'Races and Peoples'; 'The American Race'; Gerland, 'Ethnography'; Tylor, 'Anthropology.'

AMOS W. BUTLER,
Zoologist and Anthropologist, Indianapolis.

Ethyl, the organic radical C_2H_5, which occurs in many carbon compounds, but which cannot exist in the free state. Its most important compound is ethyl hydrate, or ethyl alcohol (see ALCOHOL); but the iodide, C_2H_5I, which is formed by acting upon ethyl alcohol with iodine in the presence of phosphorus, is also of much importance in synthetic chemistry.

Eth'ylam'ine, an amine (q.v.) in which one or more of the hydrogen atoms of ammonia, NH_3, is replaced by the radical ethyl, C_2H_5. Three compounds of this sort are possible, and all have been actually prepared. When only one of the hydrogen atoms of the ammonia has been replaced, the resulting compound, $NH_2.C_2H_5$, is known as mono-ethylamine, or ethyl monamine; and it is this substance which is understood when the word ethylamine is used without qualification. $NH.(C_2H_5)_2$ is known as diethylamine, and $N.(C_2H_5)_3$ is called triethylamine. All three are formed when absolute alcohol is heated with zinc chloride, in closed tubes, to 500° F.; and they may then be separated by the crystallization of their picrates. Ethylamine (that is, the mono-amine) may also be prepared by boiling cyanic ether with an aqueous solution of caustic potash, absorbing the liberated gas by passing it through hydrochloric acid, and finally drying the ethylamine hydrochloride that is so formed, and distilling it with quicklime. All three of the ethylamines are alkaline, all smell of ammonia, and all combine with acids to form salts. The mono-amine is a colorless, inflammable liquid, having a specific gravity of 0.70, boiling at 68° F., and not solidifying at 220° below zero, F. Diethylamine (which may be prepared by heating the mono-amine with ethyl bromide) is also volatile, colorless, and inflammable, with a specific gravity of 0.72, and boils at 133° F., under ordinary atmospheric pressure. Triethylamine is very similar to the other two in general character. It has a specific gravity of 0.73, boils at 194° F., and its critical temperature (according to Pawlewski) is 513° F. (See CRITICAL POINT.) Triethylamine is but slightly soluble in water; diethylamine dissolves in water freely; mono-ethylamine mixes with water with a considerable rise of temperature, and the probable formation of a hydrate; though it is entirely expelled again, upon boiling.

Eth'ylene, a gaseous hydrocarbon having the formula C_2H_4, and constituting the first member of the olefine series. It is formed in the dry distillation of numerous organic bodies, but is most conveniently prepared for laboratory purposes by mixing 1 part of alcohol with 4 parts of sulphuric acid, adding enough sand to form a paste, and heating the mass over a flame. The sand takes no part in the chemistry of the process, but merely serves to regulate the action. The sulphuric acid, owing to its affinity for water, removes the elements of water from the alcohol, and thereby liberates the ethylene, $C_2H_5.OH = H_2O + C_2H_4$. Ethylene is a colorless gas, which burns with a bright flame, a five-foot burner, using the pure gas, yielding a light of 68 candle-power. It may be condensed to a transparent liquid which boils, under ordinary atmospheric pressure, at 153° F. below zero, and freezes at 272° F. below zero. Ethylene is an unsaturated compound, and combines directly with hydrogen when mixed with that gas and led over platinum black; the product of the combination being ethane, C_2H_6. Mixed with three times its own volume of oxygen, and fired by a spark, ethylene explodes with great violence. When it is mixed with chlorine in the dark, combination takes place according to the formula $C_2H_4 + 2Cl = C_2H_4Cl_2$, the new substance being an oily fluid, known as ethylene dichloride, or «Dutch liquid.» It is on account of this reaction that ethylene was formerly called «olefiant» (or «oil-forming») gas. It will be observed that the foregoing reaction is an additive one. In diffuse daylight chlorine attacks the dichloride of ethylene, with the formation of more highly chlorinated substitution products, of which the highest is C_2Cl_6.

Etienne, Charles Guillaume, shärl gē yōm ā-tē-ĕn, French dramatist: b. Chamouilly 6 Jan. 1778; d. Paris 13 March 1845. Under the first empire he was censor, editor-in-chief of the ‹Journal of the Empire,› and a member of the Academy; at the Restoration he was expelled from the Academy, and thereafter as editor of the «Constitutional» was a power on the side of the opposition. His comedies give proof of brilliant fancy, elegant style, and great constructive skill; ‹The Two Sons-in-Law› is the best comedy of the Imperial Era, and not unworthy of Molière. He composed many farces, vaudevilles, operettas, and spectacular pieces, which had unbounded success; and his operas, ‹Cinderella› and ‹Joconde,› were the delight of Paris. He wrote a ‹History of the French Theatre.›

Etienne du Mont, ā-tē-ĕn dü môṅ (Fr. «Saint Stephen of the Mount»), a fine church of mediæval Paris. It was founded in 1220; its completion and restoration were begun in 1517, and the building reached its present perfection in 1626. The shrine of Saint Genevieve, heroine and patron saint of Paris, is its principal point of antiquarian interest, but it is also the burial-place of Pascal and Racine.

Etiolation, ē″tĭ-ō-lā′shŏn, the alteration in the color and the structure of plants due to the absence of light during growth. The most noticeable changes are paleness and elongation of the stems. The elongation is due to the extension of the cells, and the paleness to the non-development, arrested development or destruction of the chlorophyll or green coloring matter of the plant. Other phenomena are imperfect development of leaves, altered method of branching, and various modifications of tissues, especially in the imperfect development of the cell-walls, which do not attain normal thickness. Agriculturally, etiolation is either a fault to be shunned or a useful process. In the first case it is often responsible for the «lodging» of wheat and other grain-crops sown too thickly, the bases of the stems being shaded so much that the cells fail to develop normal strength, and when the heads form the wind easily beats down the plants. The sprouting of potatoes, turnips, etc., is also undesirable. But etiolation is utilized in the blanching of various plants, such as asparagus and sea-kale, and especially salads such as celery, endive, and chicory. The process involves the exclusion of light by means of earth banked around the stems, by boards, paper, etc., or by tying the outer leaves loosely over the inner ones as with endive or with cauliflower. Rhubarb is often grown in darkness. In general, tenderness and modifications in flavor are the chief ends sought in the process.

Etiquette, ĕt′ĭ kĕt, a collective term for the established ceremonies and usages of society. Among courts the Byzantine and Spanish courts, and the French court under Louis XIV. and Louis XV., were noted for the strictness of their etiquette. Social etiquette consists in so many minute observances that a tolerable familiarity with it can be acquired only by a considerable intercourse with polite society. Quickness of sympathy and a certain fineness of observation are more needed for proficiency in this sphere than mere power of intellect.

Etive, ĕt′ĭv, **Loch,** an inlet from the Firth of Lorne, on the west coast of Scotland. The scenery of its shores is very beautiful. About three miles from the sea, at Connel Ferry, a ridge of sunken rocks crossing it causes a turbulent rapid, which at half-tide forms a sort of waterfall. Salmon and other fish are plentiful.

Etlar, Carit, pseudonym of Karl Brosböll, Danish realistic novelist: b. Friderica 7 April 1816. His first story was ‹The Smuggler's Son› (1839); of his later writings, the historical tale of ‹The Queen's Captain of the Guard› and the realistic story ‹The People in Need› (1878) are the most popular; his verse also has merit. An edition of his collected works was published 1859–68; with an additional collection in 1873–9; a new edition appeared in 1888.

Et′na, or **Ætna,** a volcano in the eastern part of the province of Catania, on the island of Sicily, and the largest active volcano in Europe. Directly north is the valley of Alcantara, on the west and south, the valley of Simeto, and on the east, the Ionian Sea. From the waters on the east Etna rises cone-like to a height of about 10,875 feet; but on the south and west it seems formed of superimposed mountains, the terminal being surrounded by a number of cones, all of volcanic origin, about 100 of which are of considerable size. The circumference at the base is about 100 miles. Around the mountain and on the lower slope are a number of villages, cultivated fields, groves of olive-, orange-, fig-, and date-trees; and a little higher up is a belt of forest with oak, birch, beech, and coniferæ. Above 7,000 feet vegetation is scanty, the cone is almost bare; rocky precipices, lava beds, masses of ashes and scoriæ are visible at its summit except where covered by snow. A deep depression, Val de Bove, on the eastern side, was once the principal crater; and frequently lava has issued out of the sides of the mountain, thus forming small cones and craters, about 200 of which are now distinctly marked. From the summit may be seen the whole of the island of Sicily, the Lipari Islands, Malta, and Calabria. The eruptions of Etna have been numerous and many of them destructive: more than 80 have been recorded, 11 of which occurred before the Christian Era. That of 1169 A.D. overwhelmed Catania and buried 15,000 persons in the ruins. In 1669 the lava spread over the country for 40 days, and 10,000 persons are estimated to have perished. In 1693 there was an earthquake during the eruption, when over 60,000 lives were lost. One eruption was in 1755, the year of the Lisbon earthquake. Among more recent eruptions are those of 1852, 1865, 1874, 1879, 1886, 1892. An eruption is ordinarily preceded by premonitory symptoms of longer or shorter duration. In Greek mythology there are found frequent allusions to Etna, especially in the legends of Enceladus and Hiphæstus. Consult: Dana, 'Characteristics of Volcanoes'; Kneeland, 'Volcanoes.'

Etna, Pa., borough in Allegheny County, on the Allegheny River, the Pittsburg & W., the Etna & M., and a branch of the Pennsylvania R.R.'s. It is really a suburb of Pittsburg, with only the Allegheny River between. The chief industries are in connection with the iron and steel products for which this part of the State is so famous. Pop. 5,482.

E'ton, England, town, in the county of Buckingham, on the Thames, 22 miles west of London. It consists principally of one narrow street, which has of late years been much improved. An iron bridge across the Thames connects Eton with Windsor, from which it is separated only by the river. Eton derives its celebrity from its college. Pop. 3,309.

Eton College is one of the famous English public schools, and was founded by Henry VI. in 1440, under the name of "The College of the Blessed Virgin Mary Beside Windsor." The present collegiate edifice was begun in 1441 and the whole of the original structure was completed about 1523. Important additions were made in 1846, and also in 1889. This school was intended originally for the benefit of the sons of worthy but poor parents, and also for the support of 25 poor infirm men; and was to be maintained out of the incomes from the royal demesne lands. Now the students admitted are the sons of the gentry and nobility, and so numerous are the applicants that it is usual to enter the names at birth. The scholarships are open to all British subjects; but candidates must be 12 years or over and not more than 14 years, and must pass an examination. A certain number of the students, not under 17 years, are elected each year to scholarships at King's College, Cambridge. The number of pupils on the foundation is limited to 70, but the number outside, called oppidans, who board and lodge in the houses of the masters, is about 1,000. The course of instruction is mainly classical, but the modern languages, mathematics, and the natural sciences are given now a due share of attention. Consult: Cust, 'Eton College'; Lyte, 'History of Eton College' (1440–1898).

Etorofu, ā'tō-rō-foo, or **Iturup,** ē-too-roop', (1) an island; (2) a strait; in the most northerly part of Japan. The island belongs to the Kurile group.

Etruria, ē-troo'rĭ-a (Greek *Tyrrhenia*), the name anciently given to that part of Italy which corresponded nearly with the modern Tuscany, and was bounded by the Mediterranean, the Apennines, the river Magra, and the Tiber. The name Tuscia, for the country, came into use in late times, while Tusci, as well as Etrusci, was used by the Romans as the appellation of the people from an early period. The oldest inhabitants of the country belonged, according to the accounts of the ancients, to the Umbrian stock, and were dispossessed by the Tyrrhenians or Tyrsenians, a people who came by sea, and who were generally believed to be Lydians. These again were in early times subjected by another race who called themselves Rasena, and who finally became incorporated with the Tyrrhenians proper, the whole nation then being called Tuscans or Etruscans. These Rasena, by ancient writers usually confounded with the Tyrrhenians, entered Italy at a very early period from the north, and gradually took possession of the whole country from the Alps, Ticino, and lower Adige on the south.

To what race the Etruscans belonged is unknown, and our ignorance is equally great with regard to their language, remains of which still exist in numerous inscriptions mostly on tombs. It appears to have been quite distinct from the languages of the rest of Italy, but attempts to connect it with the Greek, Celtic, Germanic, or Semitic languages have had little or no success. The characters used are essentially the ancient Greek, and were either introduced from Magna Græcia or possibly from Corinth. Etruria was very early a confederation under the rulers of the 12 principal cities, each of which formed a republic by itself. The chiefs of these republics were styled *lucumones*, who were also the priests and generals, and held their meetings in the temple of Voltumna, where they deliberated together on the general affairs of the country. In all the cities there appears to have been an aristocracy, toward which the mass of the common people stood in the relation of clients, though there would no doubt be a body of entirely free men resembling the plebeians at Rome. The religion of the Etruscans offers a subject of great difficulty, but it is at least certain that it had many points in common with the religious systems of the Sabines and Latins, while in some respects it shows evidences of an Eastern origin. Among the deities may be mentioned Tina or Tinia, corresponding to the Latin Jupiter; Cupra, corresponding to Juno; Menerfa (Minerva); Sethlans (Vulcan); Turms (Mercury); and Aplu or Apulu (Apollo).

The chief occupations of the Etruscans were agriculture and commerce, both maritime and overland. Grain, wine, timber, cattle, and wool seem to have been the principal articles of trade. The staple food of the common people was pulse, but the upper classes were notorious for extravagance in their diet as well as in dress and in furniture. Their knowledge of the arts and sciences is said to have been derived mainly from Greece, and in a less degree from Egypt. The iron mines and copper mines in the interior of Etruria were worked at a very remote period, and the metallurgical skill shown by the Etruscans was obviously connected with their proficiency in the art of working in bronze, silver, gold, etc. Of Etruscan architecture our knowledge is limited. The so-called Tuscan order seems to be little else than a modification of the Doric. Of their temples there exist no traces; the theatres have been more fortunate, that at Fiesole showing how much in this form of construction they owed to the Greeks. The sepulchres, which were always subterranean, but frequently having superstructures of an architectural character surmounting them, present many varieties of construction.

For articles in terra-cotta the Etruscans were especially celebrated. These were not restricted to small objects, but embraced statues and figures of large size, with which the exteriors and interiors of their temples were adorned. Closely related to this branch of art was the Etruscan pottery, in the manufacture of which they excelled: but the only extant productions of this class that can be said to be genuine are the red ware of Arretium and the black ware of Clusium ornamented with figures in relief, many of them of a grotesque and strongly marked Oriental character. On the other hand, numbers of the painted vases popularly known as Etruscan vases, are undoubtedly productions of Greek workmen, the subjects, the style, and the inscriptions being all Greek. The skill of the Etruscans in works of bronze is attested by many ancient writers, and also by numerous extant specimens. The style of art characteristic of these works is stiff and archaic, having some resemblance to the early Greek, though some of the existing specimens exhibit more freedom of design and great beauty of execution. The bronze candelabra, of which many examples have been preserved, were eagerly sought after both in Greece and Rome. Another branch of art which seems to have been peculiar to this people was that of the engraved bronze mirrors, a considerable number of which has been discovered, some quite recently. These mirrors were polished on one side, and have on the other an engraved design, taken in most cases from Greek legend or mythology. Consult Dennis, 'The Cities and Cemeteries of Etruria' (1892).

Etruria, Kingdom of, the name given to the province of Tuscany, in Italy, when, in 1801, Napoleon formed of it a kingdom, and made Florence the capital. In 1808 he incorporated it with the French empire, and in 1809 his sister, Elise Bacciocchi, was made grand duchess of Tuscany. The country came under the control of Ferdinand III., when Napoleon became an exile in 1815.

Etruscan Vases, a class of beautiful ancient painted vases made in Etruria, but not strictly speaking a product of Etruscan art, since they were really the productions of a ripe age of Greek art, the workmanship, subjects, style, and inscriptions being all Greek. They are elegant in form and enriched with bands of beautiful foliage and other ornaments, figures and similar subjects of a highly artistic character. One class has black figures and ornaments on a red ground — the natural color of the clay; another has the figures left of the natural color and the ground painted black. The former class belong to a date about 600 B.C., the latter date about a century later, and extend over a period of about 350 years, when the manufacture seems to have ceased. The subjects represented on these vases frequently relate to heroic personages of the Greek mythology, but many scenes of an ordinary and even of a domestic character are depicted. The figures are usually in profile.

Ettlingen, ĕt'lĭng-ĕn, Germany, town in the grand duchy of Baden, on the Alb, five miles south of Carlsruhe. It is an ancient place, containing some Roman remains; is entered by three gates, and has an old castle with gardens, town-house, hospital, normal and other schools, manufactures of linen and cotton goods, starch, leather, and paper. Pop. 8,156.

Ettmüller, Ernst Moritz Ludwig, lood'vĭg ĕt'mül-lĕr, German philologist and historian: b. Gersdorf, Saxony, 5 Oct. 1802; d. Zürich 15 April 1877. He made extensive researches in German mediæval literature and was author of 'German Dynasty Founders' (1844); and other epic poems, besides the 'Anglo-Saxon Lexicon' (1852).

Ettrick, ĕt'rĭk, a district of Scotland, in Selkirk, through which the Ettrick water runs. It is now a sheep pasture, denuded of wood, but in ancient times it formed part of Ettrick Forest, which included the whole county as well as parts of Peebles and Edinburghshire. The "Ettrick Shepherd," James Hogg, was a native of this district.

Ettrick Shepherd, The. See Hogg, James.

Ettwein, ĕt'vīn, **John,** American Moravian bishop: b. Trendenstadt, Würtemberg, 29 June 1721; d. Bethlehem, Pa., 2 Jan. 1802. He came to America in 1754, and for nearly 50 years worked among the Moravians as evangelist, pastor, and bishop. He traveled thousands of miles, oftentimes on foot, preaching in 11 of the 13 colonies and in what is now the State of Ohio, "in cities, in villages, in homesteads, from pulpits, in the open air, in court-houses and barns, to many and very different classes of men," as he himself wrote. Among the Indians, too, he worked with great success. In 1776–7 he rendered noble service to the sick and wounded of the American army in the general hospital at Bethlehem, Pa. Elected bishop in 1784, he presided over his church for nearly 17 years, displaying the soundest judgment in matters of polity, and a fine personal heroism in critical circumstances. In 1787 he founded the Society for Propagating the Gospel Among the Heathen, which still exists, richly endowed, and is the bulwark of the extensive Moravian mission work. He became proficient in the language of the Delaware Indians, prepared a dictionary and phrase book of it, and in 1788 compiled an account of the language with a vocabulary, which has since been published by the Pennsylvania Historical Society. Old age compelled his retirement from active service in 1801.

Et'ty, William, English painter: b. York 10 March 1787; d. there 13 Nov. 1849. He worked long without much recognition, but at length in 1820 won public notice by his 'Coral Finders.' In 1828 he was elected an academician. Among his works, which were greatly admired, are a series of three pictures (1827–31) illustrating the 'Deliverance of Bethulia by Judith'; 'Benaiah one of David's Mighty Men'; 'Women Interceding for the Vanquished.' All these are very large pictures, and are now in the National Gallery of Scotland. Others of note are: 'The Judgment of Paris'; 'The Rape of Proserpine'; 'Youth at the Prow';

and 'Pleasure at the Helm.' In coloring and the representation of the nude he displayed high ability.

Etymologicum Magnum (Gr. «the great etymological glossary, or dictionary»), the sole lexicon of size surviving from the Byzantine age of Greek learning. It is evidently a compilation from other works of the same class, and bears no author's name. The book may be attributed to the 10th century. It consists of a number of quotations from the works of ancient grammarians, arranged alphabetically. It may have received its name from its first critical editor, Sylburg, or from its printer, Calliergus. The book is of high philological value, although many of the derivations of words contained in it are fanciful and utterly unscientific.

Etymology (Gr.), the investigation of the origin or derivation and of the original signification of words. It forms a subsidiary part of the science of comparative philology, and, though it has occupied the attention of the learned and the curious in every age, it is only within the 19th century that its study has been pursued on really scientific principles. Ignorance, or what is still more dangerous, half-knowledge, has often suggested false etymologies, and many more have sprung from that excess of confident and self-sufficient ingenuity which will not take plain words like *beef-eater* and *welsh-rabbit* for what they are. Folk-etymology properly so called, has played an important role in the development of languages. The words that the people have known from infancy are for them things, but it is quite different with the new terms they meet. These arrest their curiosity, and, as they believe that every word has its signification, they seek for this, guided by resemblances of sound with words already known, and consequently reach conclusions often hopelessly distorted by false analogies. We see the same illogical process in the Old Testament interpretation of personal names, applied conveniently after the fact; in the Homeric explanation of the names of gods and men; in the quaint etymologies so common in the mediæval writers, and in such moderns as Thomas Fuller; in the vagaries of Celtic topographers; and even in the pages of some modern dictionaries it is possible to find such a statement as that the English word *news* is derived from a certain conjunction of the points of the compass, north, east, west, and south. These whimsical etymologies were laughed at by Dean Swift, whose *ostler* = *oatstealer*, was a stroke of genius, but have not yet disappeared; and, indeed, the modern ideas of method in etymology are hardly at all beyond the point attained by the grammarians of Alexandria and by Varro among the Romans. It was the birth of philology and the study of the languages of the East that made a scientific etymology possible. It no longer sought the relations of the words of a single language exclusively within itself, but extended its view to the whole group of cognate tongues, or, wider still, to a whole family, and became a new science under the name of Comparative Grammar. Grimm's Law was the first finger-post that pointed out the path; among his greatest successors are Curtius and Fick. The Teutonic revival in England in the 19th century commenced the history of English upon an historical method, from which has grown a really scientific English etymology, as seen in the dictionaries of Prof. Skeat and Dr. Murray. No more useful chart of warning could be given than the former's canons for etymology: «Before attempting an etymology, ascertain the earliest form and use of the word, and observe chronology. If the word be of native origin, we should next trace its history in cognate languages. If the word be borrowed, we must observe geography and the history of events, remembering that borrowings are due to actual contact.» See Curtius, 'Grundzüge der Griechischen Etymologie' (1879); Fick, 'Vergleichendes Wörterbuch der Indo-germanischen Sprachen' (1874–6); Palmer, 'Folk-Etymology' (1882); also see SCIENCE OF LANGUAGE.

Eu, ė (Lat. *Auga*), France, town in the department of Seine-Inférieure, two miles above the mouth of the Bresle; 17 miles northeast of Dieppe. It was in the castle belonging to this place that William the Conqueror married Maud of Flanders. The town was burned to the ground in 1475, by order of Louis XI., to prevent it from falling into the hands of the English. It has several small manufacturing establishments. Pop. 5,412.

Eua, ā-oo'ä, a small island belonging to the Friendly Islands, owned by Great Britain; area, about 125 square miles. The climate of all the islands of the Tonga group, to which the Friendly Islands belong, is but slightly higher than that of the Samoan Islands, just north.

Eubœa, ū-bē'a, formerly called NEGROPONT, a Greek island, the second largest island of the Ægean Sea. It is 90 miles long, 30 in greatest breadth, reduced at one point to four miles. It is separated from the mainland of Greece by the narrow channels of Egripo and Talanta, and is connected with the Bœotian shore by a bridge. There are several mountain peaks, one over 7,000 feet. The island is well wooded and remarkably fertile. Wine is a staple product, and cotton, wool, pitch, and turpentine are exported. The chief towns are Chalcis and Karysto. The island was anciently divided among seven independent cities, the most important of which were Chalcis and Eretria, and its history is for the most part identical with that of those two cities. With some small islands it forms a modern nomarchy, with a population of 103,442 in 1901.

Eubulides (ū-bū'lĭ-dēz) **of Miletus,** Greek philosopher: the best known of the disciples of Euclid of Megara, flourished about the middle of the 4th century B.C. His life was a struggle against Aristotle, in which by a captious logic he sought to prevail against good sense. A partisan of the Megaric principle, that there is nothing real but what is always one, simple, and identical, he immediately found an adversary in the founder of the great contemporary school which made experience the condition of science. He attacked the peripatetic doctrine, like Zeno of Elea, by striving to show that there is none of our experimental notions which does not give place to insolvable difficulties.

Eubulus, ū-bū'lŭs, Greek comic writer: fl. at Athens about 375 B.C. His subjects were chiefly mythological, and many of his plays contained parodies of the tragic poets, especially Euripides.

Forest Cover for Parks, Los Angeles, California.

Avenue Shade Trees, near Santa Monica, California.

Eucaine. See COCAINE.

Eucalyptus, ū-ka-lĭp'tŭs, a genus of trees and a few shrubs of the natural order *Myrtaceæ.* The species, of which there are about 140, are characterized by simple unsymmetrical leaves, whose edges usually turn toward the sun; generally white, bell-shaped flowers, sometimes solitary, but commonly in terminal or axillary umbels near the ends of the twigs; calyx-lobes joined to form a lid, which falls off when the flower opens (from this feature the genus is named); numerous stamens; and many-seeded, angular fruit-capsules. With the exception of about half a dozen species which are natives of the East Indies and the Malay Peninsula, the members of the genus are indigenous to Australasia, where they are among the most common forest trees. The various species are highly valued for planting in parks and along avenues; for the gum-resin which oozes from their trunks; for the volatile oil contained in their leaves; for the tannin obtained from their bark; for the fibre of their inner bark; and for their powers of transpiring immense quantities of water, a quality made use of in swampy districts to get rid of excessive moisture, especially when such cannot be readily removed by drainage. They have been widely distributed by man in warm climates, particularly in the British possessions. But above all these things they are valued for their timber, which is extensively used for wharf, ship, bridge, and house building, telegraph poles, railroad ties, implements, furniture, etc. To obtain it the trees are frequently ring-barked about the beginning of the warm season so as to exhaust the sap as much as possible. After standing until the end of the dry season they are felled. Some of the species are among the largest living trees of the world. Specimens exceeding 450 feet in height and with a girth of 50 feet are occasionally reported, and trees of 400 feet in height are often found.

Few species are hardy, but many are cultivated for ornament where they can be given shelter from cold winds, or where, like other tender ornamental plants, they can be removed to a house during the winter. In California a majority of the species thrive in the open air, and are valued for their striking habits of growth, their foliage, etc. They are readily propagated from seeds sown in light, sandy soil. The seedlings should be transplanted when about four inches tall, and again at rather frequent intervals, to insure the formation of fibrous roots near the surface, thus to secure them a good start when transplanted to final quarters. Transplanting should always be done in cool, moist, cloudy weather. When once established they demand no further attention than ordinary pruning and training.

Among the best known species are the following: *Eucalyptus globulus,* the blue-gum, which often exceeds 300 feet in height, has bluish or grayish smooth bark, except at the base. It is noted for its rapid growth, the unpleasantly flavored nectar of its blossoms, which are very attractive to bees, and its ability to withstand long periods of drought. It is the most frequently planted species in California, where it is also becoming naturalized by means of its seeds. It is also planted to some extent in Florida and other Gulf States, and is said to survive a temperature as low as 20° F. It is one of the most valuable of timber trees and is one of the chief sources of oil of eucalyptus. A somewhat hardier species (*E. viminalis*), popularly known as manna gum, attains about the same size, but has either dark-colored persistent bark or light-colored deciduous bark. In California, where it is also spreading like the former, it has withstood lower temperatures and made phenomenal growths, in some instances exceeding 70 feet in height and 3 feet in girth in 12 years. It is valuable for its nectar, of which bees are very fond, but its timber is less valuable than that of the preceding species, being less strong. It is frequently used for fencing, shingles, and other purposes where strain is not expected. Perhaps the most valued is *E. marginata,* the jarrah tree or wood, which often attains heights exceeding 70 feet without the development of any limbs, and at that height often has a girth of 15 feet. It is not hardy. Its wood is especially valued for wharf and ship building, since it is not attacked by the teredo or shipworm. It is also highly esteemed for underground work, such as ties and telegraph poles, and, being easily worked and polished, is popular for house finishing and furniture. The largest species is probably *E. amygdalina,* the peppermint-tree, which is also noted for its abundant yield of oil. Its timber is not strong, but is largely used for staves, shingles, building, etc. *E. robusta,* the swamp-mahogany gum, is perhaps the species most frequently planted in swampy places. Its timber is remarkably durable and is used, like that of *E. marginata,* but is somewhat less esteemed. It is one of the finest of avenue trees, and one of the best for bees because of its abundant nectar and profuse bloom.

In medicine the oil of eucalyptus is used for its antiseptic and stimulating properties. It is very widely used in affections of the nose, mouth, and bronchi, and in diseases of the bladder and urethra. It makes a very agreeable and efficient drug to add to antiseptic mouthwashes, and is useful internally as an intestinal antifermentative. Trees of eucalyptus have been planted, especially in low marshy places, with a belief in their beneficial effects against malaria. It is frequently asserted that they have a direct action on malaria. By the aid they furnish in converting marshes into dry land they also help to prevent the development of mosquitoes, some forms of which are known to be the chief agents in the spread of malarial disease. (See MALARIA; VOLATILE OILS.) Consult: Bailey 'Cyclopedia of American Gardening' (1900–2); Mueller, 'Eucalyptographia'; Bentham, 'Flora Australiensis,' Vol. III.; Pepper, 'Eucalyptus in Algeria and Tunisia, from an Hygienic and Climatological Point of View' (Proceedings of the American Philosophical Society, Vol. 35, pp. 39–56); Cooper, 'Forest Culture and Eucalyptus Trees.'

Eucharis, ū'ka-rĭs, a genus of plants of the natural order *Amaryllidaceæ,* the species which, mostly natives of Colombia, are perennial herbs with perennial bulb-like rootstocks, broadly ovate leaves, and very showy white flowers in umbels upon long, strong scapes. They are very popular hot-house plants because of their beauty and the prolificacy of their long-lasting flowers. They are easily grown in coarse fibrous soil which will permit of abundant watering without danger of stagnation. Partial shade and rather high temperature are also needed. The best-known species is probably *E. grandiflora*, which is popularly known as star-of-Bethlehem and Amazon lily. The flowers of this species are borne upon a scape often exceeding 18 inches in height and bearing two to four star-like and very fragrant flowers, often four inches in diameter.

Eucharist, ū'kā-rĭst, in the Roman Catholic Church, the sacrament of the body and blood of Jesus Christ, and also the Christian covenant sacrifice. Regarding the Eucharist as a sacrament the Roman Catholic Church teaches that it is the true body and blood of Jesus Christ under the "species" or appearances or physical properties of bread and wine. The institution of this sacrament by Christ is recorded in the three synoptic gospels and in St. Paul's first letter to the Corinthians. The name given to the sacrament comes from the expression in the original Greek text of Luke xxii. 19, ἐυχαριστησας (eucharistesas), "having given thanks." The words of institution, as given by the same evangelist, are: "This is my body which is given for you. . . . This is the chalice, the new testament in my blood, which shall be shed for you." The perpetuation of this sacrament is commanded in the words, "This do for a commemoration of me" (1 Cor. xi. 24). A year before the institution of the sacrament Jesus Christ in a discourse at Capernaum, spoke of his flesh being "meat indeed" and his blood "drink indeed"; and it is important to note the circumstances in which he employed those extraordinary expressions. He had already said: "I am the bread of life," at which the Jews murmured. Thereupon Jesus, instead of modifying the expression which offended them, re-enforced it, saying: "The bread which I will give is my flesh for the life of the world." At this the Jews again murmured, but Christ does but emphasize the doctrine in the words already quoted. And not only the Jews were scandalized by these speeches: many of his disciples even would no longer listen to him; they "went back and walked no more with him." Would the apostles also desert him? and he elicited from them a profession of implicit faith in his words, however "hard" his sayings might be.

And that attitude of the apostles is the attitude of the Roman Catholic Church. Those words of her Founder and the many other announcements he made touching this sacramental mystery, the Roman Catholic Church from apostolic times has received in their plain literal interpretation — the interpretation put upon them by all who heard them, Jews, disciples, apostles, and by Jesus Christ himself: the Roman Catholic Church teaches that in the Eucharist is contained "truly, really, and substantially" the body and blood of Jesus Christ, together with his soul and divinity. Here nothing is added to, nothing taken away from, the words of Christ, and nothing explained away in those "words of eternal life." And when in the 11th century the Church's reading of those words as denoting a "true, real and substantial" change of the bread and wine into Christ's body and blood was challenged by Berengarius, who, more "spiritually-minded" than the apostles of Jesus Christ, would fain see in Christ's words only a figurative, symbolical presence of his body and blood in the sacrament, the Roman Catholic Church adopted the fittest possible word to express the change wrought in the bread and wine — the word Transubstantiation: in the Eucharist the substance of bread and wine remain no longer underlying the outward appearances, "species" of bread and wine: what underlies them now is the body and blood of Christ. Such is the teaching of the Roman Catholic Church with regard to the real presence of Jesus Christ in the Eucharist.

But the Eucharist is not only a sacrament: it is also the perpetual New Covenant sacrifice, believed to have been foretold by the prophet Malachi, as rendered in the Vulgate, which differs slightly from the authorized Anglican version: "From the rising of the sun even tc the going down thereof, my name is great among the Gentiles, and in every place there is sacrifice, and there is offered to my name a clean oblation" (Mal. i. 10–11). And the Roman Catholic Church teaches concerning the Eucharistic sacrifice or the Mass that "it is one and the same sacrifice with that of the cross: the victim is one and the same, Jesus Christ, who offered himself, once only, a bloody sacrifice on the altar of the cross. The bloody and unbloody victim is still one and the same, and the offering upon the cross is daily renewed in the Eucharistic sacrifice, in obedience to the command of our Lord, 'Do this in remembrance of Me.' "— *Catech. Conc. Trid., cap. de Eucharistiæ Sacr.*

Euchlo'rine, a name given by Sir Humphry Davy to the yellow gas obtained by acting upon potassium chlorate with hydrochloric acid. Davy believed it to be a new oxide of chlorine; but it is now known to be a mixture of chlorine and chlorine peroxide, ClO_2. It has powerful bleaching and disinfecting properties, but it is frightfully explosive, and should never be prepared nor handled save by an expert chemist, provided with proper safeguards, and with a full previous knowledge of its properties.

Euchre, ū'kėr, a game of cards, said to be of German origin, the most generally played parlor game after whist in the United States. The pack of cards consists of 24, being an ordinary "deck," minus the deuce, trey, four, five, six, seven, and eight spots of each suit. The game is usually played by two, three, or four persons, the most interesting party being four, two playing on each side as partners. When choice of partners and first dealer shall have been decided five cards are dealt, usually two at once, then three, or the contrary. In throwing around for partners and dealers the holder of the best card deals. The cards rank in value as follows: The best euchre card is the knave of trumps; the second best is the knave of the suit of the same color as the trump. The former card is called the "right bower," the latter the "left bower." After the right and left bowers the cards rank as at whist, the knaves of the color not turned as trumps falling into their regular place as at whist. The object of the game is to take tricks. The score is five points, unless otherwise agreed. The non-dealer may "pass," or "order up" the trump. Should he pass, then the dealer may take up the trump and discard. In that case the dealer must make three tricks or be "euchred," which counts two points for the adversary, but if he makes the three tricks (or four), he counts one point. Should he make all five tricks, it is termed "a march," and counts him two on the score. The non-dealer has the first lead, after which he who takes the trick leads. Should the non-dealer "order up" the trump he must make three tricks or be "euchred," which counts two for his opponent, if he win three tricks (or four), having ordered up the trump, he scores one point. Should he make "a march," he scores two. If both players pass (the dealer turning down the trump), and then both decline to make a trump, there must be a new deal. Either party naming a new suit for trump must make the three tricks or be "euchred." In four-handed euchre the same counts are made and the same rules practised as in the two-handed game, together with the following: The opportunity to "pass," "order up," "assist," or "play alone" goes around in rotation, beginning with the player on the left of the dealer. "To assist" is for the partner of the dealer to say "I assist," which has the same effect as ordering up the trump, and is subject to the penalty of two points to the adversary, should three tricks not be secured by the party "assisting" and his partner. Either partner ordering up a trump or making a trump may "play alone," that is, play his hand singly against the other two, his partner not playing his hand that round at all. "Progressive euchre" is played by a number of participants at separate tables, the successful players moving up in a regular order. A prize is generally awarded to the two winners.

Euchologion, ū-kō-lō'jĭ-ŏn, the liturgical and ritual book of the Greek Church, answering to the Missal, which is the Pontifical and Ritual of the Latin Church. The Uniate Greek Church, or Church of the Greek Rite in communion with the See of Rome, has a separate Euchologion.

Euclase, ū'klās, a rare gem mineral, a basic silicate of glucinum and aluminum, HBe Al SiO_5. It occurs in Brazil, Siberia, and Austria, in brilliant, transparent, colorless to pale-green or blue crystals of monoclinic forms, and has a hardness of 7.5.

Euclid (ū'klĭd) **of Megara**, Greek philosopher, the founder of the Megaric school of philosophy. He was a pupil of Socrates, after whose death, 399 B.C., he retired to Megara (most probably his native city) and set up a school of philosophy, in which he blended the doctrines of the Eleatic school with those of his master. He adopted the Eleatic notion of one universal unchangeable existence, and upon this he engrafted the ethical views of Socrates. From its subtlety and disputativeness, the school of Euclid was sometimes called the Dialectic or Eristic. Nothing has survived of Euclid's work and the date of his death is unknown.

Euclid of Alexandria, Greek mathematician: fl. about 277 B.C., and taught geometry at Alexandria in the reign of Ptolemy Soter, and extended the boundaries of mathematical science. The severity and accuracy of his method have never been surpassed. His 'Elements,' in 13 books, still form the most usual introduction to the study of geometry. See GEOMETRY, ELEMENTARY PURE; MATHEMATICS.

Eudæmonism, the doctrine that happiness (Gr. *eudaimonia*) is the chief good. Happiness, according to Aristotle, is the activity of soul in accordance with virtue, virtue being the mean between excess and defect as determined by reason. See ETHICS.

Eudialyte, ū-dī'a-līt, a rhombohedral red mineral of vitreous lustre, translucent or nearly so; its hardness, 5.5; specific gravity, 2.90 to 3.01. It consists principally of silicates of iron, zirconia and lime. There are two varieties, eudialyte proper, of which the double refraction is positive, and eucolite, in which it is negative. It is found in North Greenland, Norway, and Arkansas.

Eudiom'eter, an instrument employed in the analysis of gaseous mixtures. It was originally designed for ascertaining the quantity of oxygen contained in any given bulk of elastic fluid. The first instrument of this kind was constructed by Priestley. In one form of eudiometer two platinum wires are inserted near the top of a graduated glass tube open at the bottom. An electric spark is introduced by these wires. The process involves the explosion and combustion of one of the constituents to be determined. The operation may be conducted in a trough of mercury or over water. See GASOMETRIC ANALYSIS.

Eudists, ū'dĭsts, a congregation or society of secular priests founded in the 17th century by a priest named Eudes; for the purpose of conducting ecclesiastical seminaries and giving "missions" in parish churches, for the revival of religious zeal and the conversion of sinners. The members of the society take no religious vows, but they live in common and are voluntarily subject to the orders of their superior. They do not wear any habit to distinguish them from the rest of the secular clergy. Their first house was established at Caen in Normandy 1643; the membership at that time consisted of Eudes and eight other priests. In his time Eudes conducted 110 missions in various places in the kingdom. The institute never spread to other countries. Eight or more Eudists were among the priests who were butchered in the wholesale slaughter of priests, monks and bishops at the Carmes, Paris, September 1792. The society was broken up during the French Revolution, many of the members seeking refuge in England. In 1826 the apostolate was revived and resumed with ardor and great success.

Eudocia, ū-dō'shĭ-a, Roman empress: b. Athens about 393; d. Jerusalem about 460. She was a daughter of Leontius the philosophical sophist. After the death of her father, who left nearly all his property to his two sons, she went to Constantinople for the purpose of complaining of this injustice to the emperor, Theodosius II. There she embraced the Christian religion, was baptized as Eudocia and became empress 421 A.D. She was afterward divorced and spent the remainder of her life in Jerusalem, engaged in acts of devotion. She is said to have written some Greek poems and also a life of Christ.

Eudoxia, ū-dŏk'sĭ-a, Byzantine empress: wife of Arcadius, emperor of the West: d. 409. She was the daughter of Banto, a Frankish general of Theodosius; and Eutropius, the eunuch, intriguing against Rufinus, chief minister of Arcadius, induced the emperor to take her to wife, instead of marrying the daughter of Rufinus, as the latter had designed. Eutropius soon after this union caused Rufinus to be put to death and succeeded him. Eudoxia, if we may believe John Chrysostom, was an infamous creature, although at one time winning his admiration and profuse acknowledgments by an open profession of religious earnestness. She was a woman of strong passions and resolute will, and when Eutropius insulted her by saying that as he had raised her so he could debase her, she appealed to the weak Arcadius, who at once degraded Eutropius from all his honors, and ordered his statue in the market place of Constantinople to be destroyed. Chrysostom so vehemently inveighed against the court life of Eudoxia that she caused him to be banished in 403, but popular clamor, added to the panic caused by an earthquake, induced her to recall him. But her enmity caused his second exile in 404. She survived this persecuted prelate only two years, and if she were too impatient under the almost Aristophanic invective of a bishop who was more a monk than a courtier, she was probably sincere in her anxiety to rescue the feeble Arcadius from the dominion of a minister like Eutropius, and the best act she ever did in her life was to bring this monster of profligacy and corruption to the end of his career.

Eudoxia, Roman empress. She was the daughter of Theodosius II.; b. Constantinople 422; d. about 463. She was married to her cousin Valentinian III., emperor of the West, after whose death, by the hands of emissaries of the senator Maximus, she was constrained to espouse the latter. Maximus subsequently had the folly to reveal to her the part which he had taken in the murder of Valentinian, and when the time for vengeance seemed to her to have come she invited to Italy Genseric, king of the Vandals, at whose approach Maximus was murdered. Genseric delivered Rome to pillage, and bore away with him to Africa Eudoxia and her two daughters.

Eudoxians, ū'dŏk'sĭ-a̤nz, followers of Eudoxius, who from 356 A.D. was bishop of Antioch, in Syria, and from 360 to his death in 370 bishop and patriarch of Constantinople. He was successively an Arian, a Semi-Arian and an Aëtian. Respecting the Trinity, he believed the will of the Son to be differently affected from that of the Father.

Eudoxus (ū-dŏk'sŭs) **of Cnidos,** Greek astronomer, lived about 370 B.C., was the scholar and friend of Plato. All his works are lost, but the poem of Aratus on astronomy makes us acquainted with the extent of his astronomical knowledge. Eudoxus seems to have been the first to introduce an astronomical globe into Greece, and this may account for the great reputation which he acquired and long continued to enjoy.

Eufaula, ū-fâ'la̤, Ala., city in Barbour County, on the Chattahoochee River, and on the Central Georgia Railroad; 80 miles southeast of Montgomery. It is at the head of steamboat navigation on the river; is the trade centre of a large manufacturing and agricultural district; and carries on an extensive cotton-shipping trade, exporting over 30,000 bales annually. It has gas and electric lights, waterworks plant erected by the city in 1897 at a cost of $60,000, public parks, Union Female College, public high school, and three national banks. Pop. (1900) 4,532.

Euganean (ū-gā'nē-a̤n) **Hills,** a range of well-wooded hills, lying southwest of Padua, in northern Italy. They owe their origin to eruptions of trachyte during the Jurassic Period. The highest point, Monte Venda, reaches about 1,895 feet. On their slopes stand several villas, among them Petrarch's house at Arquà. Valuable building stone and mineral springs abound.

Eugène, ė-zhān, **Prince** (François Eugène de Savoie-Carignan), Austrian general: b. Paris 18 Oct. 1663; d. Vienna 21 April 1736. Among all the generals and statesmen of Austria, none has rendered more numerous and important services than Eugène. He was great alike in the field and the cabinet. He petitioned Louis XIV. for a company of dragoons, but was refused on account of the opposition of Louvois, minister of war, who hated the family of Eugène. Indignant at this repulse Eugène, in 1683, entered the Austrian service. The distinction he earned at the siege of Belgrade in 1688, at that of Mayence in 1689, and elsewhere, procured for him rapid promotion. War having broken out between France and Austria, he prevailed upon the Duke of Savoy to enter into an alliance with the emperor, and in 1690 received the command of the imperial forces sent to Piedmont to act in conjunction with the troops of the Duke of Savoy. He defeated the Turks at the battle of Zenta (11 Sept. 1697), and obtained on that occasion the applause of Europe. The loss of the Turks at Zenta obliged them to accede to the Peace of Carlowitz 1699, which was the first symptom of their decline. In 1703 he received the command of the army in Germany; and his efficient co-operation with Marlborough frustrated the plans of France and her allies. In the battle of Höchstädt (Blenheim) 13 Aug. 1704, the two heroes gained a decisive victory over the French and Bavarian army, commanded by the Prince of Bavaria and Marshal Tallard, the latter of whom was made prisoner. In 1705 Eugène returned to Italy, where he hastened to the relief of Turin, stormed the French lines, forced them to raise the siege, and in one month drove them out of Italy. In 1707 he entered France, and laid siege to Toulon; but the immense superiority of the enemy obliged him to retire into Italy. During the following years he fought on the Rhine, took Lille, and, in conjunction with Marlborough, defeated the French at Oudenarde (1708), and Malplaquet (1709). After the recall of Marlborough and the defection of England from the alliance against France, his farther progress was in a great measure checked. The Peace of Rastadt, the consequence of the Treaty of Utrecht, was concluded between Eugène and Villars in 1714. In the war with Turkey, in 1716, Eugène defeated two superior armies at Peterwardein and Temesvar, and, in 1717, took Belgrade, after having gained a decisive victory over a third army that came to its relief. The Treaty of Passarovitz (concluded in 1718) was the result of this success. During 15 years which followed, Austria enjoyed peace, and Eugène was as active in the cabinet as he had

EUGENIE.

been in the field. Consult Malleson, 'Prince Eugène of Savoy' (1888).

Eugene, ū-jēn', Ore., city, county-seat of Lane County; on the Willamette River, the Southern P. and the O. R. & N. C. R.R.'s; 105 miles west by south of Portland, and 52 miles from the Pacific Ocean. The University of Oregon, established here in 1876, had in 1903 about 500 students. The manufactures are chiefly flour, lumber, and bricks, and some articles for home consumption. The city was settled in 1854. Pop. 3,561.

Eugene Aram, a novel by Bulwer-Lytton, published 1832. It was founded on the career of an English scholar, Eugene Aram: b. 1704; executed for the murder of one Clark in 1759. The character of the murderer and the circumstances of his life made the case one of the most interesting from a psychological point of view, in the criminal annals of England. Aram was a scholar of unusual ability, who, self-taught, had acquired a considerable knowledge of languages, and was even credited with certain original discoveries in the domain of philology. Of a mild and refined disposition, his act of murder seemed a complete contradiction of all his habits and ideals of life.

'Eugene Aram' is an unusually successful study in fiction of a complex psychological case. At the time of its publication, it caused a great stir in England, many attacks being made upon it on the ground of its false morality. To the present generation its romance is of more interest perhaps than its psychology. Thomas Hood's poem on the same theme is entitled, 'The Dream of Eugene Aram'; W. G. Wills' play, 'Eugene Ara[illegible]' was produced in 1873 by Henry Irving.

[illegible]ène de Beauharnais, ė-zhān dė bō-är-[illegible] [illegible]e BEAUHARNAIS, EUGÈNE DE.

Eu[illegible]énie, ė-zhā-nē (EUGÉNIE MARIE DE M[illegible] ODE GUZMAN Y DE PORTO-CARRERO), [illegible]press of the French: b. Granada, [illegible]pain, 5 May 1826. Her father, the Count [illegible] Montijo, was of a noble Spanish fam-[illegible] [illegible]er mother was of Scotch extraction, maiden name Kirkpatrick. On 29 Jan. 1853 she became the wife of Napoleon III. and empress of the French. On 16 March 1856, a son was born of the marriage. When the war broke out with Germany she was appointed regent (27 July 1870) during the absence of the emperor, but on 4 September the revolution forced her to flee from France. She went to England, where she was joined by the prince imperial and afterward by the emperor. Camden House, Chiselhurst, became the residence of the imperial exiles. On 9 Jan. 1873, the emperor died, and six years later the prince imperial was slain while with the English army in the Zulu war. In 1881 the empress transferred her residence to Farnborough in Hampshire. She has published 'Some Recollections from My Life' (1885).

Eugénie Grandet, ė-zhā-nē grän-dā, a novel by Honoré de Balzac. It appeared in 1833, and is included among the 'Scenes of Provincial Life.' In it, the great French master of realism depicts with his accustomed brilliant precision the life of a country girl, the only child of a rich miser.

Eugenius, ū-jē'nĭ-ŭs, the name of four popes. The first, Saint Eugenius, was elected 654; d. 657. EUGENIUS II. occupied the Roman See from 824 to 827. His election was contested by a powerful faction in the city who favored Cincinnus (Zinzinnus); and Lothaire, son of Louis le Débonnaire, who shared the empire with his father, came to Rome to quell the disturbance. On this occasion the people and clergy of Rome took the oath of fidelity to the two emperors, and promised that thereafter whenever a new pope succeeded he should, before his consecration, take oath in presence of the people and the emperor's representative to honor the emperor as the protector of the Church. The Pope was the first to take this oath; its terms were complied with at the two papal elections next following, for example, of Valentinus who filled the see three months and of Gregory IV. EUGENIUS III.: b. Pisa; d. Tivoli 7 June 1153. He was a Cistercian abbot and a close friend of Saint Bernard of Clairvaux and was elected 1145. Before his consecration the populace of Rome, led by Arnold of Brescia, effected a revolution and overturned the papal government; during a reign of a little more than eight years Eugenius was most of the time in exile, living at Viterbo, Siena, and other places in Italy and in France. EUGENIUS IV.: b. Venice 1838; d. Rome 23 Feb. 1447. He was a Celestine monk, cardinal, and bishop of Siena when he was elected successor to Martin V. 1431. On 23 July 1431 was opened the Council of Basel, convoked by his predecessor; but not one bishop was present for the opening, only theologians, abbots and canons. On 12 November the Pope ordered the council to be dissolved and convoked another council to be held in 1433 at Bologna; but the fathers of the council of Basel continued to hold their sessions; throughout his reign the Pope was in conflict with the council. From first to last the council sought primarily and almost exclusively to curb the authority of the Roman See, and in consequence there passed between Rome and Basel a succession of bulls ordering the dissolution of the council, annulling its acts, anathematizing its members; and from the other side decrees of the council declaring that general assembly of the Church to be superior in authority to the Pope, and finally a decree proclaiming Eugenius deposed and setting up as Pope Amedeo, Duke of Savoy, who assumed the style Felix V. This was the act of the council in its 35th session held 8 July 1439. At the same date there was assembled at Florence, at the call of Eugenius, a council attended by 160 Latin and some 20 Greek bishops, with the Emperor John Palæologus; at this council a reconciliation was effected between the eastern and western churches; but it stood only till its terms and conditions became known in the East, when it was repudiated by the Greek Church. The cause of the rival Pope Felix was at this time fatally weakened by the withdrawal by the emperor Sigismund of his support and by his declaring for Eugenius.

Eugenol, or **Eugenic** (ū-jĕn'ĭk) **Acid** ($C_{10}H_{12}O_2$), a substance occurring in oil of cloves, as well as in the oil obtained from the fruit of *Myrtus Pimenta*, and several others. It is a colorless, oily, aromatic liquid, resembling the phenols. See THYME.

Eugubine (ū'gū-bīn) **Tables,** the name given to seven bronze tables found in 1444 at the town of Gubbio, the ancient Iguvium or Eugubium, now in the Italian province of

Perugia, bearing inscriptions in a language decided to be that of the ancient Umbrians. These tables are the most important monument of the language in which they are written. Four are inscribed in Umbrian characters, two in Latin, and the remaining one partly in Umbrian and partly in Latin. The contents of the tables refer to the ritual of the priests of the Temple of Jupiter. Photographic reproductions of the inscriptions, with translations, are given in Bréal's 'Les Tables Eugubines' (1875–8).

Euhemerism (ū-hē'mĕ rĭzm), or **Euemerism.** See MYTHOLOGY.

Eukairite, ū-kā'rīt, a rare mineral of a shining lead-gray color and granular structure, consisting chiefly of selenium, copper, and silver. Its name is derived from the Greek word meaning *opportune,* and was given to it by Berzelius because found soon after the discovery of selenium.

Eulachon, ū'lă-kŏn, or **Candle-fish.** See CANDLE-FISH.

Eulalia, ū-lā'lĭ-a, Spanish virgin martyr: b. Merida, Estremadura; d. 12 Feb. 308 A.D. When she was only 12 years old, the great persecution of Diocletian was set on foot, whereupon the young girl left her maternal home, and, in the presence of the Roman judge, cast down the idols he had set up. She was martyred by torture.

Eulalia, a popular name for certain species of tall perennial ornamental grasses of the genus *Miscanthus* (natural order *Gramineæ*). They are natives of eastern and southern Asia. The best-known species is probably *M. sinensis,* which has developed several well-marked horticultural varieties characterized by green, mottled or striped foliage and large terminal fan-like panicles of flowers, which, after shedding their deciduous parts, are still attractive because of their persistent silky hairs, which give the panicle a delicate, fluffy appearance for which they are valued as house decorations and for everlasting bouquets. Because of their beauty, their perfect hardiness, and the ease with which they can be propagated by means of seeds or division of the roots, these plants are universal favorites, especially for bedding purposes.

Eulenburg, oi'lĕn-boorg, **Botho,** German statesman: b. 31 July 1831. In 1867 he was elected to the North German Reichstag as a Conservative; became minister of the interior in 1878 and as such formulated the famous Socialist law of October 1878. Differences with Bismarck led to his resignation of this office 1881. In 1892 he succeeded Count Caprivi as president of the Prussian ministry, but owing to controversies between Eulenburg and Caprivi over the bill for an amendment to the criminal code, the emperor dismissed them both in October 1894. In 1899 Eulenburg took his seat in the Herrenhaus, or Prussian House of Lords.

Eulenspiegel, oi'lĕn-spē-gĕl, a typical character associated in Germany with all sorts of frolics and fooling. The type originated in Till or Tyll Eulenspiegel, a German clown who lived probably in the first half of the 14th century, and became celebrated for the wild pranks and escapades that he practised in all parts of Germany, and in some of the neighboring countries. According to popular account he was born at the village of Kneitlingen, near Brunswick, and died at Mölln, near Lübeck. The tricks and frolics currently attributed to Eulenspiegel first appear in a Low Saxon account written in 1483; the earliest edition, in High German, was published at Strasburg in 1519 by Thomas Murner. This work became very popular, and was translated into nearly every European language. In English it first appeared as a miracle-play, with the title 'A Merry Feast of a Man that was called Howleglas' (Eulenspiegel meaning literally "owl-glass"). An edition of Murner's original collection was published by J. M. Lappenberg at Leipsic in 1854, and English translations and editions appeared in 1860 and 1890.

Euler, oi'lĕr, **Leonard,** Swiss mathematician: b. Basel 15 April 1707; d. St. Petersburg 7 Sept. 1783. In his 19th year he gained the *accessit* of the prize offered by the Paris Academy of Sciences for the best treatise on the masting of vessels. In 1733 he became professor of mathematics in the Academy of St. Petersburg, where he labored with astonishing industry. He composed more than half of the treatises in this branch of science contained in the 46 quarto volumes published by the St. Petersburg Academy 1727–83; and at his death left about 100 unpublished dissertations, subsequently printed by the society. In 1741 he accepted an invitation from Frederick the Great to become professor of mathematics in the Berlin Academy, but in 1766 returned to St. Petersburg. He first gave the example of those long processes in which the conditions of the problem are first expressed by algebraic symbols, and then pure calculation resolves all the difficulties. He applied the analytic method to mechanics, and enlarged the boundaries of this science. He greatly improved the integral and differential calculus, of which he afterward published a complete course, which surpassed everything then extant on this subject. An extensive optical treatise, 'Sur la Perfection des Verres object. des Lunettes,' in the Mémoires de Berlin (1747), was the result of his inquiries into the means of improving spectacles. The share which he contributed by this work toward the discovery of achromatic telescopes is sufficient to distinguish his name in this department also. He also employed himself in metaphysical and philosophical speculations. He attempted to prove the immateriality of the soul, and to defend revelation against freethinkers. In his well-known 'Lettres à une Princesse d'Allemagne, sur Divers Sujets de Physique et de Philosophie' (1768–72), he attacks the Leibnitzian system of monads and pre-established harmony. Among his numerous writings may be mentioned here his 'Theoria Motuum Planetarum et Cometarum'; 'Introductio in Analysin Infinitorum,' which has always been regarded as his greatest production; 'Institutiones Calculi Differentialis'; 'Institutiones Calculi Integralis'; 'Introduction to Algebra'; his 'Dioptrica'; 'Opuscula Analytica.'

Eumenides, ū-mĕn'ĭ-dēz. See FURIES.

Eumol'pus, a mythical personage of ancient times, celebrated as a poet, warrior, hierophant, and legislator, according to the common tradition a Thracian, the son of Poseidon and Chione, the daughter of Boreas. He is said to have been driven from Thrace, but to have afterward returned. The accounts of his subsequent career vary. According to one tradition he was the founder of the Eleusinian mysteries, in which he was instructed by Demeter. The sacerdotal family of the Eumolpides at Athens claimed to be descended from this Eumolpus.

Euno'mians, the extreme faction of the Arian sect in the 4th century, so called from the name of their leader, Eunomius, who was made bishop of Cyzicus in Mœria 360, but who was deposed the following year. For 30 years thereafter he was the foremost champion of Anomœanism, or the doctrine that Jesus Christ the son of God is of different nature (or substance) from the Father (ἀνόμοιος κατ'οὐσίαν καὶ κατά παντα : unlike in substance and everything): thus his doctrine was that of Unitarianism. The doctrine of the Roman Catholic Church, declared in the Council of Nicæa, was that of ὁμοούσιαὰ consubstantiality; that of the Semi-Arians was that the Son is of like or similar substance, ὁμοιούσιος and hence they are called homœusians, while the orthodox took the name of homousians (both words usually written homoiousians, homoousians). To give solemn expression to their distinctive tenet the Eunomians changed the baptismal formula, "I baptize thee in the name of the Father," etc., to this: "I baptize thee in the name of God, the Creator, into the death of Christ."

Euno'mius, Arian bishop: b. Dacora, Cappadocia; d. there 392. In the controversy which gave rise to Arianism, Eunomius was an ardent disciple of Arius. So extreme were his views that he and his followers were looked upon as members of a party within the Arian ranks, and were called Eunomians. He was made bishop of Cyzicus in 360, and remained at the head of this see for some years. He lived the life of an exile after this on account of his views, but finally returned to his birthplace.

Eunuch, the keeper of a harem, generally a castrated man. Eunuchism is of prehistoric origin and prevails among all nations and peoples. Eunuchs were common in biblical times.

Euonymus, ū-ŏn'ĭ-mŭs, a genus of the staff-tree family (*Celastraceæ*), comprising upward of 65 species of shrubs, natives of the north temperate zone. Six species are found in America. The best known are the strawberry bush (*E. americanus*), the burning-bush or wahoo (*E. atropurpureus*) and the spindle-tree (*E. europeus*). (See SPINDLE-TREE.) From the bark of the wahoo or burning-bush, an extract known in medicine as euonymin, is obtained. It is used as a cholagogue, tonic and diuretic, and for its stimulant action on the liver.

Euornithes, ū-ôr'nĭ-thēz, a grand division of birds, which, according to some authors, includes all living birds except the ostriches and their allies and the penguins; and according to others includes all birds, modern and extinct, except Archæopteryx. In this sense it is equivalent to the preferable term *Neornithes* (q.v.).

Eupata'ria, or **Eupatoria,** Russia, seaport, in the government of Taurida, on the Black Sea, 40 miles northwest of Simferopol. Having long been possessed by the Tartars of the Crimea (who gave it the name of Kosloff or Kesloff), it is more Asiatic than European in its aspect. The salt lake of Sakè is a bathing resort. It was here that the allied forces landed at the commencement of the Crimean war (14–18 Sept. 1854). It was unsuccessfully attacked by the Russians 17 Feb. 1855. Pop. 17,757.

Eupato'rium, a genus of composite plants including many (about 400) species, especially characteristic of America, where several are well known. Among the most prominent are boneset or thoroughwort (*E. perfoliatum*), a native of low grounds distinguished by the fact that its opposite leaves are joined around the stem; and the joe-pyr-weed, or gravel-root (*E. purpureum*), whose purplish rosy flowers become conspicuous in late summer in wet meadows borne on stems often 12 feet high. The hemp-agrimony is a well-known British medicinal herb. The flower-heads in this genus are corymbs, all the florets tubular. Several of these plants have enjoyed from time immemorial a reputation in folk-medicine as remedies for the breaking up of fevers. Popular tradition has it that eupatorium is good for broken bones, the common name boneset preserving this notion. It has no such action. By reason of a certain amount of volatile and fixed oil which eupatorium contains it makes a fair diaphoretic mixture, and in the form of "boneset tea" it is of service in causing profuse sweating. This may be of service in the treatment of congestions in different parts of the body. See DIAPHORETICS.

Eupat'rides (Gr. εὐπατρίδαι, *eupatridai*, well-born), the aristocracy, or land-owning class of ancient Athens, distinguished from the *geomiroi*, or peasants, and the *demiourgoi*, or artisans.

Eupen, oi'pĕn (Fr. *Néaux*), Germany, town in Rhenish Prussia, on the Wenze, near the frontiers of Holland, 10 miles south-southwest of Aix-la-Chapelle. Its manufactures are numerous and varied. Eupen owes its manufacturing prosperity to the French refugees, who settled here while the town formed part of the duchy of Limburg, under Austrian rule. After the Peace of Lunéville, when this duchy was ceded to France, Eupen belonged to the department of Ourthe until the Peace of Paris in 1814, when this town, with other portions of Limburg, was ceded to Prussia. Pop. 15,587.

Eu'phemism, a figure of speech by which one avoids the use of words directly expressing anything improper, disagreeable, or painful, by the employment of phrases that suggest in a more delicate manner or under a more cheerful aspect the idea to be conveyed. Thus the Greeks, in speaking of the Erinyes or Furies, came to call them the Eumenides, or well-disposed, gracious goddesses, and sometimes *semnai theai*, "the august goddesses." Nearly all languages have some euphemism for death, or to express the fact that one has died, as when we speak of the "departed." In the Bible we have the phrases "he was gathered to his fathers," "he has fallen asleep," etc.; the Romans, with the same intention, said "he has lived" (*vixit*); the Germans say "he is ascended" (*er ist hinaufgegangen*), or "he has been made immortal" (*er ist verewigt worden*).

Euphorbiaceæ, ū-fôr-bĭ-ā'se-ē (the *Spurge* family), a natural order of plants, consisting of more than 4,000 species of herbs, shrubs and trees arranged in 220 genera, some of which are well known for their ornamental and economic uses. They are, with few exceptions, natives of warm climates, especially of tropical America, and nearly every species has an acrid juice, usually poisonous, but sometimes made bland when heated. Among the members of the family are many species of commercial importance. Thus the juice of some species and the roots of others are used in medicine, for in plants of this kind are found croton oil, castor oil, etc. A few of the Euphorbiaceæ yield fragrant balsamic products; a few, although their juice is poisonous, yield a wholesome starch in considerable abundance (see MANIOC); a few are cultivated and used as pot-herbs, particularly species of *Plukenetia* in the East Indies; a few yield wholesome and agreeable sub-acid fruits, as *Cicca disticha* and *C. racemosa* in the East Indies; the seeds of some are edible, as those of the candle-nut (q.v.), etc.; the oil of the seeds is also in some cases used for food, like other bland oils, but more frequently for burning, as castor-oil, candle-nut oil, the oil of *Elæococca verrucosa* in Japan and Mauritius, and the solid oil of *Stillingia sebifera*, which is used in China for making candles, and in medical preparations as a substitute for lard. From *Hevea* is derived the highest grade of rubber produced in South America. Others yield dye-stuffs. The timber of some of the Euphorbiaceæ is valuable — for example, African teak. Of the 210 genera, 10 are represented in the American flora, the most important being Croton, Ricinus (castor-oil plants), and the Euphorbia or spurge proper. This genus numbers about 700 species, most abundant in the warm parts of the north temperate zone, more than 125 of them being found in America. They are all known as «spurge,» and are more or less poisonous. Some one species is found in every part of America, those not native having escaped from cultivation. Some of the species are imposing ornamental plants and are much used in landscape gardening, and in greenhouses, usually for their curious forms of growth, rather than for their beauty.

Plants of this family, although of widely differing forms of growth and foliage, are characterized by unisexual, monœcious or diœcious flowers often brilliantly colored and often inconspicuous, in the latter case sometimes subtended by brilliantly colored bracts; the usually three-lobed fruits split elastically when ripe and throw the seeds to greater or less distances.

Euphor'bium. See GUMS.

Euphor'bus, in Greek mythology, the son of Panthous, slain by Menelaus in the Trojan war.

Euphrasia, a genus of plants of the figwort family (*Scrophulariaceæ*). It comprises about 110 species, natives of temperate and cold regions of both hemispheres, four of them occurring in North America. They are annual or perennial low-branched herbs, with small, blue, yellow or white flowers, generally known by the name eyebright. The principal American species are: *E. latifolia*, glandular eyebright; *E. americana*, hairy eyebright, the most widely distributed, and *E. oakesii*, oakes eyebright, found only in the White Mountains. The common English eyebright, *E. officinalis* is not known in America. This is a very pretty little plant, the flowers white streaked with purple, and a yellow spot on the lip. It grows so abundantly in some places, as to give the ground an appearance of being covered with snow, during the time of its flowering, from May to September. The whole plant is slightly aromatic. It has been used with success in catarrhal inflammations of the eye, in cough, hoarseness, earache, or headache which follow after catarrhs.

Euphrates, ū-frā'tēz, a celebrated river in Asiatic Turkey, having its sources in Central Armenia, at no great distance from the shores of the Euxine, and its mouth in the Persian Gulf; length, including windings, 1,716 miles. It is formed by the junction of two large streams, called the Kara-Su and the Mourad-Chai. These two head streams unite near Kaban Maden, about lat. 38° 58′ N.; lon. 38° 30′ E.; from which point the river holds in the main a southeasterly course, until it falls into the Persian Gulf. At Korna, about 100 miles from its mouth, it is joined by the Tigris, and the united streams take the name of the Shatt-el-Arab. In point of current the Euphrates is for the most part a sluggish stream, except in the height of the flooded season. The Shatt-el-Arab has a depth of from 3 to 5 fathoms, and presents banks covered with villages and cultivation. The most important town on the Shatt-el-Arab is Bassora or Basra. The melting of the snow in the mountains along the upper part of the river's course causes the Euphrates to rise. This takes place about the beginning of March, and it increases gradually up to the end of May. The river continues high for 30 or 40 days; but afterward there is a daily decrease. From the middle of September to the middle of October the river is at the lowest. The Euphrates is navigable for a long distance from the sea, but there are numerous rapids. Steamers navigate the Shatt-el-Arab. Between the Euphrates and the Tigris lies the celebrated region Mesopotamia.

Euphrates Valley Railway, a projected road from the Mediterranean coast of Asiatic Turkey to the Euphrates valley and Persian Gulf. Projects for shortening the journey to India by the construction of a railway in the Euphrates valley have been repeatedly discussed, and some such expeditious method of reinforcing the British troops in India has been regarded as highly desirable. The schemes spoken of have been various, but the original project was to connect the Bosphorus with the Persian Gulf. In 1901 an agreement was made between the Turkish government and the German company controlling the Anatolian Railway from the Bosphorus to Konia, whereby this railway is to be continued to Bagdad and Bassorah. There is already a line from Smyrna joining the line to Konia, and this would furnish a shorter through route.

Euphrosyne, ū-frŏs'ĭ-nē (Lat., from Gr. Εὐφροσύνη, the personification of joy, from εὔφρων, *euphron*, joyous), in Greek mythology, one of the three Graces (q.v.).

Euphues (ū'fū-ēz), **or the Anatomy of Wit,** and **Euphues and His England,** a book and its sequel, by John Lyly, published respectively in 1578 and 1580, when the author was a young courtier. They constitute the first and second part of a work which can only loosely be called fiction in the modern sense. Perhaps the word «romance» best expresses its nature. For a dozen years the work was fashionable in the polite circles of England; and the word "euphuism" survives in the language to designate the stilted, far-fetched, ornate style of writing introduced and made popular by Lyly. Although Lyly's style had in it too much of the affected to give it long life, he undoubtedly did something toward making the 16th century speech refined, musical, and choice. It is this rather than any attraction of story that makes the 'Euphues' interesting to the modern student of literature.

Eu'phuism, an affected style of speech which distinguished the conversation and writings of many of the wits of the court of Queen Elizabeth. The name and the style were derived from 'Euphues, or the Anatomy of Wit' (about 1579), and the 'Euphues and His England' (about 1581), of John Lyly. These books, which became the model of the wits and gallants of the time, and an acquaintance with which was regarded as a test of courtly breeding were characterized by smoothness and verbal elegance, but chiefly by fantastic similes and illustrations. Sir Walter Scott draws the portrait of a euphuist in the character of Sir Piercie Shafton, in 'The Monastery.'

Eupion, ū'pĭ-ŏn, or Eupione, Reichenbach's name for a fragrant colorless liquid produced in the destructive distillation of various animal and vegetable substances. It is highly volatile and inflammable; it is insoluble in water, but mixes with oils, and acts as a solvent for fats and resins. It is not readily acted on by ordinary chemical reagents.

Eura'sians (syncopated from Europe-Asians), a name given to the "half-castes" of India, the offspring of European fathers and Hindu mothers. They are particularly common in the three presidential capitals — Calcutta, Madras, and Bombay. They usually receive a European education, and speak English with grammatical correctness, although with an accent not altogether agreeable to English ears. The girls, in spite of their dark tint, are generally very pretty, and often become the wives of young officers or civil officials. The sons usually receive appointments in the civil service, or become clerks in merchants' offices. They are also often spoken of as East Indians. The word Eurasian is often extended to include all persons of mixed European and Asiatic descent.

Eure, ėr, France, a department in the northwest forming part of Normandy; area 2,300 square miles. The chief river which flows through it is the Seine. The mining and manufacturing industries are extensive. Pop. (1901) 331,184.

Eure, a river of France, which has given its name to two departments — that of the Eure, and that of the Eure-et-Loir. The river rises in the department of the Orne, and flows into the Seine, near Pont-de-l'Arche, after a course of 124 miles, being navigable for about half the distance.

Eure-et-Loir, ėr-ā-lwär, France, a department in the northwest, forming part of the old provinces of Orléannais and Ile-de-France; area, 2,267 square miles. The department is essentially agricultural, and has few manufactures. The capital is Chartres. Pop. (1901) 272,624.

Eureka, ū-rē'ka, a Greek word meaning "I have found it"; used as an expression of triumph at a discovery. See ARCHIMEDES.

Eureka, Cal., city, county-seat of Humboldt County; on Humboldt Bay, the Eel River, and the San Francisco & N. W., the California N., the Eureka & K. R. R.R.'s; 225 miles northwest of San Francisco. It has a fine harbor, which has been improved by the United States government on the jetty plan. The city is situated in the famous redwood region, and has large lumber interests. Sequoia Park, a tract of 40 acres of redwood forest, is near the city. The city has gas and electric lights, high schools, daily and weekly newspapers, and five banks. Pop. (1904) 11,111.

Eureka, Ill., city, county-seat of Woodford County; on the Atchison, T. & S. F. and the Toledo, P. & W. R.R.'s; 20 miles east of Peoria. Eureka College, under the auspices of the Christian Church, was established in 1855. The city is a trade centre for the surrounding agricultural college. Pop. 2,200.

Eureka, Kan., city, county-seat of Greenwood County; on Fall River; and on the Atchison, T. & S. F. and the Missouri P. R.R.'s; about 58 miles northeast of Wichita. It is the seat of the Southern Kansas Academy, under the auspices of the Congregational Church. The city is a trade centre for the surrounding rich agricultural region. Pop. 2,236.

Eureka, Nev., town, county-seat of Eureka County; on the Southern P. R.R. Some of the richest mines of the State are near, lead, gold, and silver; and many other valuable minerals are found in Eureka and adjoining counties. The town has numerous and important smelting and refining works. Because of severe fires, destroying a large portion of the place, the population decreased from in 1880, 5,000, to in 1901, 2,000.

Eureka College, a coeducational institution in Eureka, Ill.; founded in 1855 under the auspices of the Christian Church; reported at the close of 1900: Professors and instructors, 16; students, 225; and volumes in the library, 6,500.

Eureka Springs, Ark., city and county-seat of Carroll County; situated in the Ozark Mountains in the northwestern part of the State, and on the Eureka Springs R.R., 18 miles southeast of Seligman, Mo. The city is chiefly noted for its medicinal springs and its healthful climate, and very little manufacturing is carried on. Onyx of a fine grade is found in the vicinity. The city has a high school and three graded public schools; there are two banks, with a combined capital of $50,000, and 10 church edifices. The city is lighted by gas, owns and operates its waterworks and has an electric railway system. The affairs of the community are administered by a mayor and council of six members elected every two years. It was first settled in 1879 and became a city in 1880. The population are mainly Americans. Pop. (1900) 3,572.

E. M. BARE,
Secretary Commercial Club.

Euripides, ū-rĭp'ĭ-dēz, Greek tragic poet: b. Salamis, probably 23 Sept. 480 B.C., d. 406 B.C. The date given for his birth by the Arundel marbles is 485 B.C.; and Müller upholds the date

481 B.C., on the ground that Eratosthenes states him to have been 75 at his death. The usual account, however, places it on the day of the battle of Salamis. Euripides is said to have begun to write tragedies at the age of 18, but no play was exhibited by him until 455 B.C., the year in which he exhibited the 'Peliades.' He was not successful in gaining the first prize till the year 441 B.C., and he continued to exhibit till 408 B.C., when he exhibited the 'Orestes.' Most of the short remainder of his life was passed at the court of Archelaus, king of Macedonia, where he was held in the highest honor. The honor paid to Euripides by Archelaus is not the only proof of the estimation in which he was held by foreigners. Plutarch records in his 'Nicias' that on the occasion of the destruction of the Athenian army in Sicily, under Demosthenes and Nicias, by the Syracusans (413 B.C.), many of those who survived, and were made prisoners, obtained their liberty by reciting to their masters some of the verses of Euripides, and he adds that numbers of them on their return home visited the poet to express their thanks to him. The Athenians themselves did not neglect to do honor to their great poet after his death, for Pausanias makes mention of a statue to him that stood in the theatre of Athens.

Euripides made it a chief aim to awaken the tender emotions. "He knew," says one critic, "the nature of the passions, and had the art of inventing situations in which they could have their full play. Most of his characters were once in the enjoyment of distinguished prosperity, and the retrospect, in their present situation, checks the violence of the passions, and lowers them to the tone of lamentation. For this reason, in his tragedies the passions are breathed forth in soft complaints, rather than raised to a lofty height; for the same reason he is so rich in moral sentences and philosophical declamations, as his personages have always coolness enough to reflect on their situation. Euripides knew well what was suited to produce an effect at the moment. The times of boldness, when Æschylus wrote, were past, and the power of the state was beginning gradually to sink. The pathetic manner of Euripides then became popular." Various faults may be found with his loose plan, his often unintelligible changes of character, his superfluous choruses, and sometimes, too, his subject; but he stands pre-eminent in true, natural expression of the passions, in interesting situations, original groupings of character and varied knowledge of human nature. He is a master, too, in the art of managing the dialogue, in adapting the speeches and answers to the character, the sex, and station, the known or private views, the present disposition of the speaker, and the necessity of the moment, in short, to all that gives distinctness and individuality to a person. There is, too, a certain tenderness and softness diffused over his writings, which cannot fail to please the mind. He has been often called the woman-hater; but this seems to be rather a random charge, and was made probably on account of his many severe strictures on the follies of the female sex.

The number of tragedies composed by Euripides is stated by one authority to be 75, of which only 5 are said to have gained him the prize; according to another authority the total number of his tragedies reached 92, 15 of which gained him the prize. His extant plays amount to 18, or 19 if the 'Rhesus' be included in the number, as it is by some scholars, although others reject it as spurious. The following are the extant plays of Euripides: 'Alcestis'; 'Medea'; 'Hippolytus Coronifer'; 'Hecuba'; 'Heracleidæ'; 'Supplices'; 'Ion'; 'Hercules Furens'; 'Andromache'; 'Troades'; 'Electra'; 'Helena'; 'Iphigenia in Tauride'; 'Orestes'; Phœnissæ'; 'Bacchæ'; 'Iphigenia in Aulide'; and 'Cyclops.' The works of Euripides have been translated into verse by Way (1894–8); and into prose by E. P. Coleridge (1885). See Mahaffy, 'Introduction to the Study of Euripides' (1879); Lawton, 'Three Dramas of Euripides' (1889); Decharme, 'Euripide et l'esprit de son théâtre' (1893); Verrall, 'Euripides the Rationalist' (1895); Haigh, 'Tragic Drama of the Greeks' (1876); England, 'Euripides and the Attic Oration' (1898); Nestle, 'Euripides, der Dichter der griechischen Aufklärung' (1901).

Euripus, ū-rī'pŭs, in ancient geography, the strait between the island of Eubœa and the mainland, Bœotia in Greece. At Chalcis, the width at the narrowest part was 120 feet.

Euroclydon, ū-rŏk'lĭ-dŏn, a tempestuous wind that frequently blows in the Levant, and which was the occasion of the disastrous shipwreck of the vessel in which St. Paul sailed, as narrated in Acts xxvii. 14–44. In the form in which the word is found in the revised version it must be taken as made up of the two Greek words, *euros*, the east or rather southeast wind, and *klydōn*, a wave. But the word used for it in the Vulgate is *Euro-aquilo*, a Latin compound signifying a northeast wind; and some of the best MSS. have the reading *Eurakylōn* instead of *Euroclydon*, which is accepted by some scholars as the preferable reading. Whatever may have been the true form of the word, it was applied to a northeast or north-northeast, and not an east or southeast wind, as the course taken by the vessel referred to indicates. Exactly such a wind is described by sailors of the present day as prevalent at certain seasons (especially in early spring) in the Mediterranean. The name by which the wind is now known is *Gregalia*.

Europa, ū-rō'pa, in Greek mythology, the daughter of Agenor, king of the Phœnicians, and the sister of Cadmus. The fable relates that she was abducted by Jupiter, who assumed the form of a bull, and swam with his prize to the island of Crete. Here Europa bore to him Minos, Sarpedon, and Rhadamanthus.

Europe, the smallest of the great continents but the most important, distinguished above the others by the character of its population, the superior cultivation of the soil, and the flourishing condition of arts, sciences, industry and commerce.

Topography.— Europe forms a huge peninsula projecting from Asia, and is bounded on the north by the Arctic Ocean; on the west by the Atlantic Ocean; on the south by the Mediterranean, the Black Sea, and the Caucasus range; on the east by the Caspian Sea, the Ural River, and the Ural Mountains. The most northerly point on the mainland is Cape Nordkyn, in Lapland, in lat 71° 6′ N.; the most southerly

points are Punta da Tarifa, lat. 36° N., in the Strait of Gibraltar, and Cape Matapan, lat. 36° 17′, which terminates Greece. The most westerly point is Cape Roca in Portugal, in lon. 9° 28′ W., while Ekaterinburg is in lon. 60° 36′ E. From Cape Matapan to North Cape is a direct distance of 2,400 miles, from Cape St. Vincent to Ekaterinburg, northeast by east, 3,400 miles; area of the continent, about 3,800,000 square miles. Great Britain and Ireland, Iceland, Nova Zembla, Corsica, Sardinia, Sicily, Malta, Crete, the Ionian and the Balearic Islands are the chief islands of Europe. The shores are very much indented, giving Europe an immense length of coast line (estimated at nearly 50,000 miles). The chief seas or arms of the sea are: the White Sea on the north; the North Sea, or German Ocean, on the west, from which branches off the great gulf or inland sea known as the Baltic; the English Channel, between England and France; the Mediterranean, communicating with the Atlantic by the Strait of Gibraltar (at one point only 19 miles wide); the Adriatic and Aegean seas, branching off from the Mediterranean, and the Black Sea, connected with the Aegean Sea through the Hellespont, Sea of Marmora, and Bosporus.

The mountains form several distinct groups or systems of very different geological dates, the loftiest mountain masses being in the south central region. The Scandinavian mountains in the northwest, to which the great northern peninsula owes its form, extend above 900 miles from the Polar Sea to the southern point of Norway. The highest summits are about 8,000 feet. The Alps, the highest mountains in Europe (unless Mount Elbruz in the Caucasus is claimed as European), extend from the Mediterranean first in a northerly and then in an easterly direction, and attain their greatest elevation in Mont Blanc (15,781 feet), Monte Rosa, and other summits. Branching off from the Alps, though not geologically connected with them, are the Apennines, which run southeast, through Italy, constituting the central ridge of the peninsula. The highest summit is Monte Corno (9,541 feet). Mount Vesuvius, the celebrated volcano in the south of the peninsula, is quite distinct from the Apennines. By southeastern extensions the Alps are connected with the Balkan and the Despoto-Dagh of the southeastern peninsula of Europe. Among the mountains of southwestern Europe are several massive chains, the loftiest summits being in the Pyrenees, and in the Sierra Nevada in the south of the Iberian Peninsula. The highest point in the former, La Maladetta or Mont Maudit, has an elevation of 11,165 feet; Mulahacen, in the latter, is 11,703 feet, and capped by perpetual snow. West and northwest of the Alps are the Cévennes, Jura, and Vosges; north and northeast, the Harz, the Thüringerwald Mountains, the Fichtelgebirge, the Erzgebirge and Böhmerwaldgebirge. Farther to the east the Carpathian chain encloses the great plain of Hungary, attaining an elevation of 8,000 or 8,500 feet. The Ural Mountains between Europe and Asia reach the height of 5,540 feet. Besides Vesuvius two other volcanoes are Etna in Sicily, and Hecla in Iceland. A great part of northern and eastern Europe is level. The «great plain» of north Europe occupies part of France, western and northern Belgium, Holland, the northern provinces of Germany, and the greater part of Russia. A large portion of this plain, extending through Holland and north Germany, is a low sandy level not infrequently protected from inroads of the sea only by means of strong dykes. The other great plains of Europe are the plain of Lombardy (the most fertile district in Europe) and the plain of Hungary. Part of southern and southeastern Russia consists of steppes.

Rivers and Lakes.— The main European watershed runs in a winding direction from southwest to northeast, at its northeastern extremity being of very slight elevation. From the Alps descend some of the largest of the European rivers, the Rhine, the Rhône, and the Po, while the Danube, a still greater stream, rises in the Black Forest north of the Alps. The Volga, which enters the Caspian Sea, an inland sheet without outlet, is the longest of European rivers, having a direct length of nearly 1,700 miles, including windings of 2,400 miles. Into the Mediterranean flow the Ebro, the Rhône, and the Po; into the Black Sea, the Danube, Dnieper, Dniester, and Don (through the Sea of Azov); into the Atlantic, the Guadalquivir, the Guadiana, the Tagus, and Loire; into the English Channel, the Seine; into the North Sea, the Rhine, Elbe; into the Baltic, the Oder, the Vistula, and the Duna; into the Arctic Ocean, the Dwina. The lakes of Europe may be divided into two groups, the southern and the northern. The former run along both sides of the Alps, and among them, on the north side, are the lakes of Geneva, Neuchâtel, Thun, Lucerne, Zürich, and Constance; on the south side, Lago Maggiore, and the lakes of Como, Lugano, Iseo, and Garda. The northern lakes extend across Sweden from west to east, and on the east side of the Baltic a number of lakes, stretching in the same direction across Finland on the borders of Russia, mark the continuation of the line of depression. It is in Russia that the largest European lakes are found — Lakes Ladoga and Onega.

Geology.— The geological features of Europe are exceedingly varied. The older formations prevail in the northern part as compared with the southern half and the middle region. North of the latitude of Edinburgh and Moscow there is very little of the surface of more recent origin than the strata of the upper Jura belonging to the Mesozoic Period, and there are vast tracts occupied either by eruptive rocks or one or other of the older sedimentary formations. Denmark and the portions of Germany adjoining belong to the Cretaceous Period, as does also a large part of Russia between the Volga and the basin of the Dnieper. Middle and eastern Germany with Poland and the valley of the Dnieper present on the surface Eocene formations of the Tertiary Period. The remainder of Europe is remarkable for the great diversity of its superficial structure, rocks and deposits belonging to all periods being found within it, and having for the most part no great superficial extent. Europe possesses abundant stores of those minerals which are of most importance to man, such as coal and iron, Great Britain being particularly favored in this respect. Coal and iron are also obtained in France, Belgium, and Germany. Gold is found to an unimportant extent, and silver is widely spread in small quantities. The richest silver ores are in Norway, Spain, the Erzgebirge, and the Harz Mountains. Spain is also rich in quicksilver. Copper ores are abundant in the Ural Mountains, Thuringia, Cornwall, and Spain. Tin ores are found in Cornwall, the Erzgebirge, and Brittany.

Climate.— Several circumstances concur to give Europe a climate peculiarly genial, such as its position almost wholly within the temperate zone, and the great extent of its maritime boundaries. Much benefit is also derived from the fact that its shores are exposed to the warm marine currents and warm winds from the southwest, which prevent the formation of ice on most of its northern shores. The eastern portion has a less favorable climate than the western. The extremes of temperature are greater, the summer being hotter and the winter colder, while the lines of equal mean temperature decline south as we go east. The same advantages of mild and genial temperature which western has over eastern Europe, the continent collectively has over the rest of the Old World. The diminution of mean temperature, as well as the intensity of the opposite seasons, increases as we go east. Peking, in lat. 40° N., has as severe a winter as St. Petersburg in lat. 60°.

Botany.— With respect to the vegetable kingdom Europe may be divided into four zones. The first, or most northern, is that of fir and birch. The birch reaches almost to North Cape; the fir ceases a degree farther south. The cultivation of grain extends farther north than might be supposed. Barley ripens even under the 70th parallel of north latitude; wheat ceases at 64° in Norway to lat. 62° in Sweden. Within this zone, the southern limit of which extends from lat. 64° in Norway to lat. 62° Russia, agriculture has little importance, its inhabitants being chiefly occupied with the care of reindeer or cattle, and in fishing. The next zone, which may be called that of the oak and beech, and cereal produce, extends from the limit above mentioned to the 48th parallel. The Alps, though beyond the limit, by reason of their elevation belong to this zone, in the moister parts of which cattle husbandry has been brought to perfection. Next we find the zone of the chestnut and vine, occupying the space between the 48th parallel and the mountain chains of southern Europe. Here the oak still flourishes, but the pine species become rarer. Rye, which characterizes the preceding zone on the continent, gives way to wheat, and in the southern portion of it to maize also. The fourth zone, comprehending the southern peninsula, is that of the olive and evergreen woods. The orange, lemon, and olive flourish in the southern portion of it, and rice is cultivated in a few spots in Italy and Spain.

Zoology.— As regards animals the reindeer and polar bears are peculiar to the north. In the forests of Poland and Lithuania the urus, a species of wild ox, is still occasionally met with. Bears and wolves still inhabit the forests and mountains; but, in general, cultivation and population have expelled wild animals. The domesticated animals are nearly the same throughout. The ass and mule lose their size and beauty north of the Pyrenees and Alps. The Mediterranean Sea has many species of fish, but no great fishery; the northern seas, on the other hand, are annually filled with countless shoals of a few species, chiefly the herring, mackerel, cod, and salmon.

Inhabitants.— Europe is occupied by several different peoples or races, in many parts now greatly intermingled. The Celts once possessed the west of Europe from the Alps to the British Islands. But the Celtic nationalities were broken by the wave of Roman conquest, and the succeeding invasions of the Germanic tribes completed their political ruin. At the present day the Celtic language is spoken only in the Scotch highlands (Gaelic), in some parts of Ireland (Irish), in Wales (Cymric), and in Brittany (Armorican). Next to the Celtic comes the Teutonic race, comprehending the Germanic and Scandinavian branches. The former includes the Germans, the Dutch, and the English. The Scandinavians are divided into Danes, Swedes, and Norwegians. To the east, in general, of the Teutonic race, though sometimes mixed with it, come the Slavonians, that is, the Russians, the Poles, the Czechs or Bohemians, the Servians, Croatians, etc. In the south and southeast of Europe are the Greek and Latin peoples, the latter comprising the Italians, French, Spanish and Portuguese. All these peoples are regarded as belonging to the Indo-European or Aryan stock. To the Mongolian stock belong the Turks, Finns, Lapps, and Magyars or Hungarians, all immigrants into Europe in comparatively recent times. The Basques at the western extremity of the Pyrenees are a people whose affinities have not yet been determined. The total population of Europe is about 394,000,000; nine tenths speak the languages of the Indo-European family, the Teutonic group numbering about 108,000,000, the Slavonic and Latin over 95,000,000 each. The prevailing religion is the Christian, embracing the Roman Catholic Church, the various sects of Protestants (Lutheran, Calvinistic, Anglican, Baptists, Methodists, etc.), and the Greek Church. A part of the inhabitants profess the Jewish, a part the Mohammedan religion.

Political Divisions.— The states of Europe, with their respective areas and populations, are as shown below. In addition to those given in the table, there are also the insignificant states of Andorra, Monaco, and San Marino, which still maintain a kind of precarious independence.

Area and Population.— The following table shows the countries with their government, area, and population according to the last official reports:

Countries	Government	Area in Eng. Sq. M.	Population
Andorra	Republic	175	6,000
Austria-Hungary	Empire	201,591	47,102,000

History.— Europe was probably first peopled from Asia, but at what date we know not. The first authentic history begins in Greece at about 776 B.C. Greek civilization was at its most flourishing period about 430 B.C. After Greece came Rome, which, by the early part of the Christian era, had conquered Spain, Greece, Gaul, Helvetia, Germany between the Danube and the Alps, Illyria, Dacia, etc. Improved laws and superior arts of life spread with the Roman empire throughout Europe, and the unity of government was also extremely favorable to the extension of Christianity.

With the decline of the Roman empire a great change in the political constitution of Europe was produced by the universal migration of the northern nations. The Ostrogoths and Lombards settled in Italy, the Franks in France, the Visigoths in Spain, and the Anglo-Saxons in South Britain, reducing the inhabitants to subjection or becoming incorporated with them. Under Charlemagne (771–814) a great Germanic empire was established, so extensive that the kingdoms of France, Germany, Italy, Burgundy, Lorraine, and Navarre were afterward formed out of it. About this time the northern and eastern nations of Europe began to exert an influence in the affairs of Europe. The Slavs, or Slavonians, founded kingdoms in Bohemia, Poland, Russia, and the north of Germany; the Magyars appeared in Hungary, and the Normans agitated all Europe, founding kingdoms and principalities in England, France, Sicily, and the East. The Crusades and the growth of the Ottoman power are among the principal events which influenced Europe from the 12th to the 15th century.

The conquest of Constantinople by the Turks (1453), by driving the learned Greeks from this city, gave a new impulse to letters in western Europe, which was carried onward by the invention of printing and the development of national life in the European states. The discovery of America was followed by the temporary preponderance of Spain in Europe, and next of France. Subsequently Prussia and Russia gradually increased in territory and strength. The French Revolution (1789) and the Napoleonic wars had a profound effect on Europe, the dissolution of the old German empire being one of the results. Since then the most important events in European history have been the separation of Belgium from Holland, and the establishment of the independence of Greece, both in 1830; the disappearance of Poland as a separate state; the Crimean war of 1854–56 in which Great Britain, France, and Sardinia maintained the integrity of Turkey against Russia; the unification of Italy under Victor Emmanuel; the Franco-German war, resulting in the consolidation of Germany into an empire under the leadership of Prussia, and the establishment of the Third Republic in France; the attempt of Russia in 1877 to again sweep Turkey from her rank as a European nation; the partial dismemberment of the Turkish empire, including the loss of Crete and the unsuccessful war of the Greeks against the Turks in 1897.

Bibliography.— Adams, ‘European History’ (1899); Allison, ‘History of Europe’ (1853); Bryce, ‘The Holy Roman Empire’ (1877); Duruy, ‘General History’ (1898); Dyer, ‘History of Modern Europe’ (1901); Fyffe, ‘History of Modern Europe’ (1890); Freeman, ‘Historical Geography of Europe’ (1881); Gibbon, ‘Decline and Fall of the Roman Empire’ (ed. 1902); Hassell, ‘Handbook of European History’ (1897); Lodge, ‘History of Modern Europe’ (1885); May, ‘Democracy in Europe’ (1877); McCarthy, ‘History of Our Own Times’ (1888); Munroe, ‘History of the Middle Ages’ (1902); Rose, ‘A Century of Continental History’ (1880); Robinson, ‘History of Western Europe’ (1902); Schnill, ‘History of Modern Europe’ (1902).

European Saratoga, The, Baden-Baden, famous for its medicinal waters and as a resort of fashion. Similarly, Saratoga has been named the «American Baden-Baden.»

Eurotas, ū-rō'tas, or **Iri,** a river of southern Greece (Peloponnesus), at one time called the Iris and Niris in the upper, and the Basilipotamo (King's River) in the lower part of its course, flows in a southerly direction through the valley between the ranges of Taygetus and Parnon, and enters the Gulf of Kolokytha.

Euro'tia, a genus of the goosefoot family (*Chenopodiaceæ*), which comprises two species, one of which, *E. lanata*, is found in America, and is generally known as American Eurotia or white sage. It is a many-branched herb, from one to three feet high, the flowers densely covered with long silky hairs. It is found from June to September in dry soils in the northwest Territories, from western Nebraska to New Mexico, Nevada and California. It is also called winter fat, being gathered and used as a winter forage; it has been successfully employed as a remedy for intermittent fevers.

Euryale, ū-rī'a-lē, a genus of the water lily family (*Nymphæaceæ*). It has but one species, *Euryale ferox,* a native of China and southeastern Asia. The plant is covered with spines; the flowers are small, red, or purplish, and the leaves very large, sometimes four feet in diameter. The seeds are rich in starch, and in the native countries of the plant, are an article of commerce, being roasted and eaten, or used in soups. The root is also eaten. The plant is hardy and will grow out of doors in America and reproduce itself as far north as Baltimore. In some instances it has grown for a number of years even farther north, but an unusually severe winter will kill it, unless protected.

Eurydice, ū-rid'ĭ-sē, in Greek mythology, the wife of Orpheus, who died by the bite of a serpent. Her husband, inconsolable for her loss, descended to the lower world, and, by the charms of his lyre, moved the infernal deities to grant him permission to bring her back. This they granted, on condition that he would not look back upon her till he had reached the upper world. Forgetting his promise, he looked and lost her forever. This story has often formed a subject for poets — as for Virgil in the Georgics (book iv.), and for Pope in his 'Ode on St. Cecilia's Day.' One of the first modern operas was the 'Eurydice' (Euridice) of Coccini and Peri. It was first produced at Florence in 1600. The name Eurydice was borne by certain Macedonian princesses.

Euryl'ochus. See CIRCE.

Eurymone, ū-rĭm'ō-nē, an infernal deity, who gnawed the dead to the bones, and was always grinding her teeth. Also a daughter of Apollo.

Eurynome, ū-rĭn'ō-mē, in Greek mythology, the daughter of Oceanus and mother of the Graces.

Eurypterus, ū-rĭp'tē-rŭs, a remarkable fossil arthropod related to the horseshoe crab (*Limulus*), many genera and species of which occur in Palæozoic rocks of western Europe and eastern North America. They include the largest arthropods known, and form the family *Eurypteridæ* and order *Eurypterida* of the subclass *Merostomata* (q.v.). They resembled the modern horseshoe crabs in structure, but had elongated, often scorpion-like bodies, terminating in a hinged, spike-like or flattened tail or telson. The most remarkable feature, however, is the great size they attained, some exceeding six feet long, so that they were well named by Haeckel *Gigantosraca.* The surface was formed by a thin chitinous epidermal skeleton, ornamented by fine scale-like markings, and bearing upon the head-shield two large lateral faceted eyes and a pair of median ocelli. Beneath the cephalo-thorax are six pairs of legs, the foremost preoral, the basal joints of which serve as jaws. The last pair is greatly enlarged, somewhat flattened and terminated by an oval plate, which suggests that these limbs served as paddles in swimming, but they may have been otherwise useful. In *Pterygotus* and some allied genera the preoral limbs are modified into more or less antennæ-like organs terminating in toothed pincers (chelæ), no doubt for seizing prey, etc. The ventral segments are 13, of which the first 2 bear the genital organs, and the remainder leaf-like structures regarded as respiratory and equivalent to the "bookgills" of *Limulus.* These extraordinary crustaceans are found associated with graptolites, cephalopods, and trilobites in the Ordovician; with marine crustacea in the Silurian; with oceanic fishes in the Devonian, and with land and fresh-water plants and animals in the coal measures. Their structure shows that they must have been aquatic (marine) and good swimmers; but toward the end of their race they became gradually adapted to brackish and even fresh water. The latest review of the group is in Eastman's American edition of Zittell's 'Text-book of Palæontology' (1900), which contains a full bibliography. See MEROSTOMATA.

Eurysthenes (ū-rĭs'the-nēz) **and Procles,** prō'clēz, the twin sons of Aristodemus, and the progenitors of the two royal lines of Sparta.

Eurystheus, ū-rĭs'thūs, the son of Sthenelus, and king of Mycenæ, who, at Juno's instigation, ordered Hercules to perform "the twelve labors." Hyllus, the son of Hercules, afterward killed him.

Eusden, ūs'dĕn, **Laurence,** English poet: b. Spofforth, Yorkshire (?), 1688; d. Coningsby, Lincolnshire, 27 Sept. 1730. He attracted much attention by his 'Original Poems' (1714); 'Ode for the New Year' (1720), and other poems, resulting in his appointment as poet laureate in 1718.

Eusebius (ū-sē'bĭ-ŭs) **of Caesare'a,** surnamed Pamphili, Church historian: b. probably, Cæsarea, Palestine, 264 A.D.; d. there about 349. He is known as Eusebius Cæsariensis and Eusebius Pamphili, that is, Pamphilus's Eusebius — a style assumed after the martyrdom of his instructor, Saint Pamphilus. He was chosen bishop of Cæsarea 314. Though he never subscribed to the views held by Arius and the Arians regarding the Godhead of Christ, he was always friendly toward them and thus incurred censure as being at best a Semi-Arian. Before the rise of Arianism he wrote a spirited defense of the Christian faith in refutation of a book by one Hierocles, who contended that the noted impostor, Apollonius of Tyana, was superior to Jesus Christ in sanctity and in miraculous powers. Eusebius wrote two treatises which have come down to our time: (1) the 'Preparation,' and (2) the 'Demonstration of the Gospel,' usually designated by their Latin titles, 'Præparatio Evangelica,' 'Demonstratio Evangelica.' The argument of the former is the groundlessness of idolatry, the impostures of the oracles, the monstrous impieties of the heathen mythology and theology; and the author shows that the doctrine of the unity of the Godhead, and the truth of his revealed religion is as ancient as the world. In the 'Demonstratio', the argument is that the law and the prophecies of the Jewish scriptures clearly foreshow Jesus Christ and the Gospel. Of his other works extant the chief is his 'History of the Church, from the Time of Its Founder to the year 323.' See Schöne, 'Die Weltchronik des Eusebius in ihrer Bearbeitung durch Hieronymus' (1900).

Eusebius of Em'esa, Greek ecclesiastic: b. Edessa; d. Antioch about 360. He studied under Eusebius of Cæsarea, and at Alexandria and Antioch. Averse to all theological controversies, he declined the bishopric of Alexandria vacant by the deposition of Athanasius. He was afterward, however, appointed bishop of Emesa, in Syria, but was twice driven away by his flock, who accused him of sorcery on account of his astronomical studies. The homilies extant under his name are probably spurious.

Eusebius of Nicome'dia, Arian bishop: d. Constantinople 342. He was appointed bishop of Beryta (Beirut) in Syria, and afterward of Nicomedia. He appeared as the defender of Arius at the Council of Nice, and afterward placed himself at the head of the Arian party. He baptized the Emperor Constantine in 337, and became patriarch of Constantinople in 339.

Eustachian (ū-stā'kĭ-an) **Tube,** in anatomy, a canal leading from the pharynx to the tympanum of the ear; named for the Italian anatomist, Eustachio. See EAR.

Eustachio, Bartolommeo, bär-tō-lŏm-mā'ō ā-oos-tä'kē-ō, Italian physician and anatomist: b. San Severino, Italy, soon after 1500; d. August 1574. He devoted himself to medical science and in particular to anatomy, which he much enriched by his researches. Among his discoveries were the Eustachian tube and the Eustachian valve of the heat. His 'Tabulæ Anatomicæ' was published 1714.

Eustathius (ūs-tā'thĭ-ŭs) **of Thessalonica,** Greek scholar: b. Constantinople; d. Thessalonica 1198. He was at first a monk, then a deacon and teacher of rhetoric in his native city; he was archbishop of Thessalonica from 1160, and of Myra from 1174, and died at an advanced age. Eustathius was profoundly versed in the ancient classic authors. His most important work is his commentary on Homer (1st ed. 1542–50). His commentary on Dionysius was first printed at Paris (1547). Of his commentary on Pindar, only the 'Proœmium' has come down to us; a part of his theological and historical treatises, letters, etc., was published by Tafel in 1832.

Eusta'tius, Saint, one of the Leeward Islands. See SAINT EUSTATIUS.

Eus'tis, James Biddle, American diplomatist: b. New Orleans, La., 27 Aug. 1834; d. Newport, R. I., 9 Sept. 1899. He was admitted to the bar in 1856 and practised in New Orleans till the Civil War broke out. He then entered the Confederate army and served as judge-advocate on the staffs of Gens. Magruder and J. E. Johnston till the close of the war. He was elected United States senator in 1876, but not given his seat till late in 1877; and was professor of civil law in the University of Louisiana in 1879–84, when he was again elected senator. In March 1893, he was appointed United States minister to France, and on the expiration of his term, in 1897, resumed practice in New York. He translated into English the 'Institutes of Justinian,' and Guizot's 'History of Civilization.'

Eustis, William, American physician and politician: b. Cambridge, Mass., 10 June 1753; d. Boston 6 Feb. 1825. He served as a surgeon in the American army during the Revolution, and subsequently practised medicine in Boston. He was a member of Congress 1801–5 and 1820–3; was secretary of war 1809–13; and governor of Massachusetts in 1823–5.

Eusto'ma, a genus of herbs of the gentian family, which comprises two species, natives of the Southern States, Mexico and the West Indies. The most common species is Russell's Eustoma (*E. russellianum*), which grows on the prairies from Nebraska to Louisiana, Texas and Mexico. The flowers are purple, bell-shaped, sometimes three inches in diameter.

Eutaw, ū'tâ, Ala., town, county-seat of Greene County; on the Alabama G. S. R.R.; about 95 miles southwest of Birmingham. It was settled in 1838, named in honor of the battle of Eutaw Springs, S. C. (1781), where the American forces, commanded by Gen. Greene, gained a victory. It is in a rich agricultural region. Pop. 1,008.

Eutaw Springs, a small tributary of the Santee River in Charleston County, S. C. It is noted for the battle fought on its banks in 1781. See EUTAW SPRINGS, BATTLE OF

Eutaw Springs, Battle of, 8 Sept. 1781, in the Revolution. Tactically a drawn battle, in results it was an important American victory, winning the object of Greene's campaign; as the British shortly abandoned interior South Carolina, retiring to Charleston. Greene, having captured 96, stole on the British at Eutaw, some 2,300, under Gen. Stuart, and attacked suddenly at 4 A.M. He had about 2,000 men, part militia, but with Marion and Pickens for commanders; while the regulars were the famous Marylanders under Howard and Hardman, Virginians under Campbell, North Carolinians under Sumner, and the remnant of the brave Delaware men; with William Washington, R. H. Lee, and Pleasant Henderson for cavalry leaders. The British had one line; the right on Eutaw Creek, the left in the air. The Americans had two, besides the reserves; the militia in front, who fought desperately and fired in some cases 17 rounds before giving way. Then the regulars rushed forward and swept the British line off the field; but gaining their camp, stopped to plunder it, and though rallied, could not drive the British from the strong positions they had taken. In assailing a brick house, Greene's guns were captured and he lost many of his best men; and a charge of Col. Washington's was repulsed and himself taken prisoner. Greene was obliged to retreat; but Stuart decamped in the night. The American loss was 408 regulars killed and wounded, militia probably at least 150; British, 453 killed and wounded, 257 missing.

Euterpe, ū-tėr'pē, one of the Muses, considered as presiding over lyric poetry. The invention of the flute is ascribed to her. She is usually represented as a virgin crowned with flowers, having a flute in her hand, or with various instruments about her. As her name denotes, she is the inspirer of pleasure. (See MUSES). In botany, *Euterpe* is a genus of palms found in South America and the West Indies, and embracing seven or eight species. Some specimens attain a height of nearly 100 feet. The wood of *E. oleracea* is used for flooring. Its fruit, as also that of *E. edulis,* is edible; and the latter species furnishes assai (q.v.). Euterpe in astronomy is an asteroid (No. 27), discovered by Hind in 1853.

Eutha'mia, a genus of *Compositæ,* which includes some of the golden-rods (q.v.).

Euthanasia, ū-tha-nā'sĭ-a, means, in Greek, being happy or opportune in the time of one's death. The correlative adjective is applied in Greek literature to a man who died for his country, and it has been translated by the Latin historian "felix opportunitate mortis." The term euthanasia has recently been employed by some scientific men in advocating the reasonableness of relieving the sufferings of those afflicted with incurable diseases by administering to them anæsthetics or narcotics in sufficient doses to prove fatal.

Eutro'pius, Flavius, Latin historian, who, as he himself informs us, bore arms under the Emperor Julian. The place of his birth and his history are unknown to us. He flourished about 360 A.D. His abridgment of the history of Rome 'Breviarium Historiæ Romanæ,' written in a perspicuous style, reaches from the foundation of the city to the time of the Emperor Valens, to whom it is dedicated. The best editions are those of Droysen (1878), Rühl (1887).

Eutyches, ū'tĭ-kēz, heresiarch of the Eastern Church, who flourished in the 5th century. He was a priest and archimandrite or prior of a monastery in Constantinople; was the founder of the religious sect called after him Eutychians, but also Monophysites, as believing that in Jesus Christ was but one nature, and that the Divine: μόνος, *singularis,* single, φύσις, nature. The Council of Ephesus (431) having declared that in Jesus Christ were united the divine and human nature, Eutyches was condemned as a heretic by a synod of bishops held in Constantinople 448, but the next year the "Robber Synod" of Ephesus, controlled by Dioscorus, patriarch of Alexandria, reversed that judgment. In 451 the General Council of Chalcedon annulled the decrees of the Robber Synod, excommunicated Eutyches and formulated the Catholic doctrine regarding the hipostatic union of the divine and human natures in Christ. Eutyches died in exile. His doctrine took fast root in Syria, Armenia, Mesopotamia, Egypt and Ethiopia, and in those countries the Monophysite Churches are strong to this day. See MONOPHYSITES.

Euxanthic (ūk-săn'thĭk) **Acid** ($C_{21}H_{18}O_{11}$), called also **Purreic Acid,** an acid obtained from purree, or Indian yellow. With the alkalies and earths, it forms soluble yellow compounds.

Euxenite, ūk'sē-nīt, a rare Norwegian mineral, essentially a niobate and titanate of yttria, erbia, ceria, and uranium. It sometimes contains iron calcium, and germanium, while water is always present. It occurs in orthorhombic crystals, but usually it is massive. It has a hardness of 5.5, a specific gravity of 4.6 to 5.1, a brilliant metallic-vitreous lustre, and a brownish-black color, showing a reddish-brown translucence in thin slivers.

Euxine, ūk'sĭn, the ancient name for the Black Sea.

Eva, Little, a beautiful child, who becomes the friend and consoler of Uncle Tom in Harriet Beecher Stowe's novel 'Uncle Tom's Cabin.' Her early death forms one of the climaxes in that affecting story.

Evadne, e-văd'nē, in Greek fable, the daughter of Mars and Thebe, who threw herself into the funeral pile of her husband, Cateneus.

Evagoras, e-văg'ō-ras, king of Salamis in Cyprus, flourished about the beginning of the 4th century B.C. His family had been expelled by a Phœnician exile. Evagoras recovered the kingdom in 410 B.C., and endeavored to restore in it the Hellenic customs and civilization. He was friendly with the Athenians, and in return for his services a statue was erected to him at Athens. His increasing power attracted the jealousy of the Persian king, Artaxerxes II., who declared war against him and besieged Evagoras in his capital. He was saved only by the dissensions of his enemies, and was able to conclude in 385 a peace by which the sovereignty of Salamis was secured to him.

Evagrius (e-văg'rĭ-ŭs) **Scholas'ticus,** Syrian Church historian: b. Epiphonia about 536; d. after 594. He wrote the history of the Church in continuation of the ecclesiastical histories of Eusebius, Socrates, Theodoret and Sozomen from 431, the date of the Council of Ephesus, to 594. His surname, Scholasticus, indicates that he was by profession (probably at Antioch) an advocate, for such at that time was a usual meaning of the word: he was legal adviser to Gregory, patriarch of Antioch, who commended him for his fidelity and learning to the emperor, Tiberius Absimarus, and obtained his promotion to a judicial office. In recognition of his eminent integrity as an official of the empire his second marriage was made the occasion of a public festival; which, however, had a disastrous ending, for it was interrupted by a violent earthquake, which caused the loss of thousands of lives.

Evan'der, in classical legend, the civilizer of Latium, the son, according to one account, of Hermes and an Arcadian nymph. About 60 years before the Trojan war he established himself in Latium, and built, at the foot of the Palatine Hill, on the banks of the Tiber, a town, to which he gave the name of Pallantium. The Roman legends represent him as teaching the Latins the use of the alphabet, and the arts of agriculture and music, softening their fierce manners by the introduction of more humane laws, and introducing among them the worship of the Lycæan Pan, Heracles, Demeter, etc. In the Æneid Virgil brings his hero Æneas into connection with Evander, who gives him a favorable reception, and becomes his ally against the Latins. Divine honors were paid to Evander by the inhabitants of Pallantium in Arcadia.

Evald, ā'vält. See EWALD.

Evangel'ical, a word literally signifying "pertaining to the gospel," and used in different senses. In one of its senses it is a term used to qualify certain doctrinal opinions, especially strong views on the question of the atonement, justification by faith, and allied doctrines. In this sense the word, when applied to a whole church, is in Scotland almost synonymous with orthodox; and in the United States it has much the same significance, in contrast to the words "liberal" and "rationalistic." In England the Evangelical or Low Church party is looked upon as extreme in its views, and is distinguished from the orthodox party, which holds the doctrines above specified in a more moderate form. When used in a less general sense something more is implied in the word. It indicates peculiar attachment to sound doctrine and peculiar fervency in advocating it. In another sense the term is applied in Germany to Protestants as distinguished from Roman Catholics, inasmuch as the former recognize no standard of faith except the writings of the evangelists and the other books of the Bible, and more especially to the national Protestant Church, formed in Prussia in 1817, by a union of the Lutheran and Calvinistic churches.

Evangelical Alliance, an association of members of the different sections of the Christian Church, organized in London 19–23 Aug. 1846. At this meeting was adopted a doctrinal basis, which is, in effect, the recognition by the members of the divine inspiration, authority, and sufficiency of the Holy Scriptures; the right of private judgment in their interpretation; the unity of the Godhead, and the Trinity of persons therein; the doctrine of human depravity in consequence of the fall; the incarnation, atonement, intercession, and mediatorial reign of the Son of God; justification by faith alone; the work of the Holy Spirit in conversion and sanctification; the immortality of the soul, the resurrection of the body, and the final judgment of the world resulting in the eternal blessedness of the righteous, and the eternal punishment of the wicked; the divine institution of the Christian ministry; and the obligation and perpetuation of the ordinances of baptism and the Lord's Supper. The American branch of the alliance was organized in 1867. Conferences of the entire alliance have been held in 1851, 1855, 1857, 1861, 1867, 1873, 1879, 1885, 1891, that of 1873 having met in New York. The American branch held a conference at Chicago in October 1893. The alliance has aided largely in the promotion of religious liberty in Europe and the East.

Evangelical Association, a religious denomination founded in Pennsylvania about the beginning of the 19th century by Jacob Albright, a member of the Methodist Episcopal Church, who was born in Pennsylvania 1759, and from about 1790 traveled among the German population as an evangelist. Albright founded a society of converts in 1800, which so increased in numbers that it was finally organized in 1807 as the Evangelical Association of North America with Albright as bishop. The theology of the association as defined in its 21 articles closely resembles that of the Methodist Episcopal Church, from which, also, it differs little in government and form of worship. The Church was divided in 1891, when a minority, numbering 40,000, organized the United Evangelical Church. In 1901 the association had 27 annual conferences, including 1 in Japan, 1 in Switzerland, and 2 in Germany; 476 local and 1,088 itinerant preachers, and property valued at $6,125,430. Consult: Orwig, 'History of the Evangelical Association' (1858).

Evangelical Counsels, in Catholic theology, are distinguished from divine commandments in this, that the commandments are of universal obligation for whoever would be saved, while the Evangelical Counsels point to the readiest and surest means of attaining that end. When a certain ruler put to Jesus Christ the question: "What good thing shall I do that I may inherit life?" and received the answer: "If thou wilt enter into life, keep the commandments," he was taught the condition of salvation which applies to all mankind. But he wanted to know whether there is not a more excellent way: he had "observed all those things from his youth up"; was there not some other "good thing" for him to do? Then Jesus prescribed to him the perfect way: "Sell all that thou hast and distribute unto the poor," giving him one of the Evangelical Counsels, the counsel of voluntary poverty. The celibate life is commended by St. Paul as more favorable to entire devotion to the service of God than the state of marriage: that Evangelical Counsel is the principal topic of the epistle of 1 Corinthians. Finally, entire obedience is the third of those counsels — renunciation of self-will, cheerful submission to the rule of superiors. Members of the religious orders of the Catholic Church bind themselves by solemn vows to practise the three Evangelical Counsels: poverty, chastity, and obedience.

Evangelical Union, the name of a religious body, also familiarly known as the Morisonians, from the Rev. James Morison, of Kilmarnock, by whom, with three other clergymen, it was founded in Scotland in 1843. The Morisonians maintain the universality of the atonement, combining with this the doctrine of eternal personal and unconditional election. In point of church government the members of the Evangelical Union are independent. The body had in 1899 between 90 and 100 congregations, chiefly in Scotland, and 712 ministers. Consult: Ferguson, 'History of the Evangelical Union' (1876).

Evangeline, e-văn'jĕ-lĭn, the heroine of one of Longfellow's earlier narrative poems, to which her name is given. It is written in English hexameters, and describes, although with little real topographical delineation of scenery, the deportation of the Acadians by the English government in 1775.

Evangelical Christian Science. See Sabin, Oliver C.

Evan'gelist (a bringer of good tidings), in the New Testament, a preacher of the gospel, distinguished (Eph. iv. 11) from the apostles, prophets, pastors, and teachers. The term came ultimately to refer to only the authors of the four Gospels, but in modern times has been extended to indicate also an unattached preacher whose specific work is the arousing of personal interest in matters of religion.

Evans, Arthur John, English archæologist: b. Nash Mills, Hertfordshire, 1851. He is a son of Sir John Evans (q.v.). He was educated at Harrow, Oxford, and Göttingen, and has been keeper of the Ashmolean Museum, Oxford, from 1884. Since 1893 he has superintended archæological researches in Crete, excavating in 1900–2 the pre-historic palace of Knossos. He has published: 'Through Bosnia' (1895); 'Illyrian Letters'; 'Antiquarian Researches in Illyricum' (1883–5); 'Cretan Pictographs and Pre-Phœnician Script' (1898); 'The Mycenæan Tree and Pillar Cult' (1901); etc.

Evans, Augusta Jane. See Wilson, Augusta Jane Evans.

Evans, Clement Anselm, American lawyer: b. Stewart County, Ga., 25 Feb. 1833. He was graduated at the Augusta, Ga., Law School 1852; established himself in practice; was county judge 1854–5, and State senator 1859–60. During the Civil War he served in the Confederate army as acting major-general in the Army of Northern Virginia. After Gen. Lee's surrender he entered the Methodist Episcopal ministry, and served until 1890. He has written a 'Military History of Georgia'; and edited the 'Confederate Military History' (12 vols.).

Evans, Edward Payson, American author: b. Remsen, N. Y., 8 Dec. 1833. He has made a special study of Oriental languages; in 1884 became connected with the 'Allgemeine Zeitung,' of Munich in Europe, to which he contributed many articles on the literary, artistic, and intellectual life of the United States. He has published 'Summary of the History of German Literature' (1869); 'Progressive German Reader' (1870); 'Animal Symbolism in Ecclesiastical Architecture' (1896) 'Evolutional Ethics and Animal Psychology' (1898); etc.

Evans, Elizabeth Edson Gibson, American prose writer: b. Newport, N. H., 8 March 1833. She was married to Edward Payson Evans (q.v.) 1868. She has published: 'The Abuse of Maternity' (1875); 'Laura, an American Girl' (1884); 'A History of Religions' (1892); 'Story of Kasper Hauser' (1892); 'The Story of Louis XVII. of France' (1893); 'Transplanted Manners' (1895); 'Confession' (1895); 'Ferdinand Lassalle and Helen von Dönninger' (1897); 'The Christ Myth' (1901).

Evans, Frederick William, American writer: b. Bromyard or Leominster, England, 9 June 1808; d. Mount Lebanon, N. Y., 6 March 1893. He removed to the United States in 1820; joined the United Society of Believers (Shakers) at Mount Lebanon, N. Y., in 1830, and became an elder in that society. The best known of his works are: 'Compendium of the Origin, History, and Doctrines of the Shakers' (1859); 'Autobiography of a Shaker' (1869); 'Shaker Communism' (1871); 'The Second Appearing of Christ' (1873).

Evans, Sir **George De Lacy,** British general: b. Moig, Ireland, 1787; d. London 9 Jan. 1870. He entered the army in 1806, and in the beginning of 1814 was sent to America, and at the battle of Bladensburg (24 Aug. 1814) had two horses shot under him. At the head of 100 men he forced the capitol at Washington. He was twice wounded before New Orleans in December 1814, and was on that account sent home to England, where he recovered just in time to be able to join Wellington at Quatre-Bras and Waterloo. In 1846 he was raised to the rank of major-general. At the outbreak of the Crimean war he was appointed to the command of the second division of the British army, and distinguished himself at the battle of the Alma, the siege of Sebastopol, and the battle of Inkermann. For his services he received the thanks of the House of Commons, the Grand Cross of the Bath, and had the cross of a grand officer of the Legion of Honor conferred on him by Napoleon III.

Evans, Henry Clay, American politician: b. Juniata County, Pa., 18 June 1834. He served in the 51st Wisconsin Infantry, enlisting 1864, and subsequently settled in Chattanooga, Tenn., as an iron and railway-car manufacturer, and was mayor of Chattanooga for two terms. He sat in Congress in 1889–91, and was assistant postmaster-general 1889–93. His election as governor of Tennessee 1894 was disputed and the opposing Democratic candidate was seated. He stood second in the vote for vice-president at the National Republican convention 1896, was appointed United States commissioner of pensions in 1897, and became consul-general in London 1902.

Evans, Hugh Davy, American author: b Baltimore, Md., 26 April 1792; d. there 16 July 1868. He studied law, began practice in Baltimore in 1815; and became eminent as a jurist. He was editor of 'The True Catholic' 1843–56; was connected with various other papers. He was a prominent member of the Maryland Colonization Society, and prepared a code of laws for the Maryland colony in Liberia; and in 1862–64 lectured on civil and ecclesiastical law. Among his writings are: 'Essays on Pleading' (1827); 'Maryland Common-Law Practice' (1837); 'Theophilus Anglicanus' (1851); 'Essays on the Episcopate of the Protestant Episcopal Church in the United States' (1855); 'Treatise on the Christian Doctrine of Marriage' (1870).

Evans, John, American geologist: b. Portsmouth, N. H., 14 Feb. 1812; d. Washington, D. C., 13 April 1861. He served on several State and Territorial geological surveys; and discovered remarkable fossil deposits in the Bad Lands of Nebraska. He was afterward commissioned by the United States government to carry on the geological surveys of Washington and Oregon.

Evans, John, American philanthropist: b. Waynesville, Ohio, 9 March 1814; d. Denver, Col., 3 July 1897. He was graduated at the medical department of Cincinnati College in 1838; in 1848 became a professor in the Rush Medical College of Chicago, in which city he accumulated a large fortune by investments in real estate. Much of this he gave to philanthropic objects. He established the Northwestern University, and endowed two chairs in it with $50,000 each. In 1862 he was appointed governor of the Colorado Territory. Later he established the University of Denver, to the construction of which he gave $200,000 and a large endowment. He gave largely for the erection of the Grace Methodist Episcopal Church in Denver, and aided almost every educational institution and Methodist Episcopal Church in the State.

Evans, Sir **John,** English archæologist: b. Britwell Court 17 Nov. 1823. His publications include: 'The Coins of Ancient Britons' (1864, supplement 1890); 'The Ancient Stone Implements, Weapons, and Ornaments of Great Britain and Ireland' (1872, 2d and enlarged edition 1897); 'Ancient Bronze Implements, Weapons, and Ornaments of Great Britain and Ireland' (1881). From 1878 till 1896 Sir John Evans was treasurer of the Royal Society, and he presided over the Toronto meeting of the British Association in 1897. He has also been president of the Geological Society (1874–6), of the Numismatic Society (1874–96), and of the Society of Antiquaries (1885–92), and he is a corresponding member of the Institute of France. His great work on stone implements received a prize from the French Academy, and both it and his other work on bronze implements were translated and published in Paris shortly after they appeared in England.

Evans, Mary Ann, or **Marian.** See Eliot, George.

Evans, Oliver, American inventor: b. Newport, Del., 1755; d. New York 25 April 1819. In 1777 he invented a machine for making card-teeth. Two years later he entered into business with his brothers, who were millers, and in a short time invented the elevator, the conveyor, the drill, the hopper-boy, and the descender, the application of which to mills worked by water-power effected a revolution in the manufacture of flour. For some years after these improvements were perfected, the inventor found much difficulty in bringing them into use, although in his own mill the economy of time and labor which they effected was very manifest. About 1799 or 1800 he set about the construction of a steam-carriage; but finding that his steam-engine differed in form as well as in principle from those in use, it occurred to him that it could be patented and applied to mills more profitably than to carriages; and in this he was completely successful. This was the first steam-engine constructed on the high-pressure principle; and to Evans, who had conceived the idea of it in early life, and in 1787 and again in 1794-5 had sent to England drawings and specifications, the merit of the invention belongs, although it has been common to assign it to Vivian and Trevethick, who had had access to Evans' plans. In 1803-4, by order of the board of health of Philadelphia, he constructed the first steam dredging machine used in America, consisting of a flat scow with a small engine to work the machinery for raising the mud. Evans also invented the boiler known as the "Cornish boiler." He wrote: 'The Young Engineer's Guide'; and 'Miller and Millwright's Guide.' See Thurston, 'Growth of the Steam-engine' (1878).

Evans, Robley Dunglison, American naval officer: b. Floyd Court House, Floyd County, Va., 18 Aug. 1846. He was appointed to the United States Naval Academy from Utah in 1860, was promoted ensign in 1863, and in 1864-5 was on board the Powhatan of the North Atlantic blockading squadron. He participated in both attacks on Fort Fisher, in 1868 was commissioned lieutenant-commander, in 1870-1 was on duty at the navy yard, Washington, in 1871-2 at the Naval Academy. Having served in 1873-6 successively on the Shenandoah and the Congress, of the European station, he was made commander in 1878; in 1891-2 was in command of the Yorktown at Valparaiso, Chile, and in 1893 became captain. During the Spanish-American war he was in command of the Iowa, and at the naval battle of Santiago he took an important part in the destruction of Cervera's fleet. In 1901 he was commissioned rear-admiral, and in 1902 was made commander of the Asiatic fleet, with the flagship Kentucky. He published 'A Sailor's Log' (1901).

Evans, Thomas Williams, American dentist: b. Philadelphia 23 Dec. 1823; d. Paris 14 Nov. 1896. He studied dentistry and practised in Maryland and later in Lancaster, Pa., and made a specialty of saving teeth by filling. In seeking a substitute for gold foil he mixed rubber and sulphur, which made a black substance instead of a white one. Because of the unfavorable color he laid the substance aside and gave it no more thought till his mixture was used by others for producing commercial gutta-percha, which he declared he had discovered. In 1848 he went by invitation to Paris as the most skilful American dentist, to attend to the teeth of President Louis Napoleon. During his career in Paris he accumulated a very large fortune. He also won an international reputation as an expert in military sanitation, and was one of the founders of the Red Cross Society. His home was the refuge of the Empress Eugénie from the mob on the night of 4 Sept. 1870. Dressed in his wife's clothes, she was taken by him to the Normandy coast, where he secured her escape to England. He bequeathed all of his fortune, estimated at from $8,000,000 to $12,000,000, excepting $250,000, to establish a museum and institute in Philadelphia.

Evans, William, Canadian agriculturist and author: b. Cavan, Ireland, 1786; d. Montreal, Canada, 1857. He emigrated from Ireland to Canada in 1819, became secretary of the first agricultural society in Montreal, in 1837 contributed a series of letters on agriculture to the *Courier,* and subsequently established the 'Canadian Quarterly' and the 'Agriculturist and Industrial Magazine.' In 1842 he edited in Toronto the 'British American Cultivator,' and in 1843 founded the 'Canadian Agricultural Journal' at Montreal. He became secretary and treasurer of the board of agriculture, Lower Canada, in 1853. His writings further include 'The Theory and Practice of Agriculture' (1835).

Ev'anston, Ill., city in Cook County, on Lake Michigan, and on the Chicago & N. W., and the Chicago, M. & St. P. R.R.'s; 12 miles north of Chicago. It includes the villages of Rogers Park and South Evanston; is delightfully laid out; and has gas and electric light plants; electric and elevated railroads to Chicago; Holly system of waterworks, weekly newspapers, and a national bank. It is the seat of Northwestern University (M. E.) founded in 1854, largely endowed and of high repute, with a library of 25,000 volumes and a museum. It is the seat also of the Garrett Biblical Institute, Winchell Academy, of the Evanston College for Women, founded in 1871, and the Visitation Academy. The Dearborn Observatory was transferred here from Chicago in 1888, and dedicated the following year as a department of Northwestern University. Evanston was the home of Frances Willard (q.v.). It is really a residential suburb of Chicago. Pop. (1900) 19,259.

Evanston, Wyo., city and county-seat of Uinta County, 76 miles east of Ogden; on the Bear River and the Union Pacific railway. There are valuable coal mines in the vicinity, and the surrounding region is also largely devoted to stock-farming and agriculture. Oil has been discovered in the neighborhood. Among the local industries are a large flouring-mill and railway repair shops. The State Asylum for the Insane is situated here. Pop. (1890) 1,995; (1900) 2,110.

Evansville, Ind., a city and port of entry of Vanderburg County, of which it is the county-seat, about 185 miles west of Louisville, 192 miles northeast of Cairo, and 180 miles southwest of Indianapolis; on the Ohio River, and the Louisville, E. & St. L., the Louisville & N., the Evansville & T. H., and other railways. It is pleasantly located on a high bank of the river.

Industries, etc. Evansville is the chief shipping point for southwestern Indiana, and ranks highly among the commercial centres of the State. According to the government census for 1900 there were in that year 705 establishments representing manufacturing and mechanical industries, with a capital of $10,059,375 and buildings valued at $1,913,592, employing the average number of 7,279 wage-earners with total wages of $2,883,975. The cost of materials used was $7,504,660, and the value of products $14,193,320. The neighboring region abounds in coal and the local coal trade is a large one. There is also an important trade in flour, pork, tobacco, grain, and timber. There are machine-shops and foundries, plow-works, furniture factories, flouring-mills, and manufactures of cottons and woolens, brick and tile, pottery, terra-cotta and fire-clay products, malt liquors, and saddlery and harness. The wharfage and shipping facilities are excellent.

Public Institutions, Buildings, etc.— The prominent buildings include the United States custom-house, the court-house, the city-hall, the Willard Library, the State Hospital for the Insane, Evans Temperance Hall, and the United States Marine Hospital. There are also three parks. Daily and weekly newspapers are published.

History, Government, etc.— Evansville was founded by Gen. R. M. Evans in 1816, became the county-seat of Vanderburg County in 1819, and was incorporated in 1847. The government is administered by a charter of 3 March 1893, with amendments of 11 March 1895. This instrument provides for a mayor, elected for four years, and a common council, one member from each ward for one year and four councilmen at large for two years. The annual expenditure of the municipality is about $700,000, the annual income about $940,000. The municipality owns the waterworks, which are operated at a yearly expense of about $30,000. Pop. (1890) 50,750; (1900) 59,007; (1903 est.) 61,482.

Evansville, Wis., a village of Rock County, 17 miles northwest of Janesville and 22 miles south by east of Madison; on the Chicago & Northwestern railway. Among its industries are an extensive wind-mill factory, an iron-foundry, and two large tobacco warehouses. Pop. (1890) 1,523; (1900) 1,864.

Evapora'tion (Lat. *evaporatio,* from *evaporare,* to emit vapor), the formation of vapor at the free surface of a liquid. In evaporation a portion of the liquid escapes in the gaseous form from the general mass, and, rising into the space, spreads through it according to the laws of diffusion of gases. Supposing the temperature of the space above the liquid to be uniform, the evaporation proceeds (provided there is a sufficient quantity of liquid) until the space is uniformly filled with vapor. A space thus filled with the maximum quantity of vapor corresponding to the temperature of it is said to be saturated. If the dimensions of the space be diminished, a portion of the vapor is forced to condense; if the temperature of the space falls, a portion of the vapor condenses also; while if the temperature of the space is increased, the dimensions remaining unchanged, the space ceases to be saturated, because the quantity of the vapor that corresponds to saturation is greater the higher the temperature. When there is not a sufficient quantity of liquid present to saturate the space completely, the whole of the liquid evaporates, and the vapor diffuses uniformly through the space. The space is then said to be non-saturated. See BOILING POINT; VAPOR.

Evart, Mich., a village of Osceola County, 60 miles east of Ludington, and 76 miles west-northwest of East Saginaw; on the Muskegon River and the Flint & Père Marquette railway. It is located in the centre of an important lumbering region, and has, besides saw-mills and shingle manufactories, a machine-shop and a foundry. Pop. (1890) 1,269; (1900) 1,360.

Evarts, Jeremiah, American editor and missionary secretary: b. Sunderland, Vt., 3 Feb. 1781; d. Charleston, S. C., 10 May 1831. He was graduated at Yale 1802, and settled in New Haven as a lawyer. His life was largely devoted to the interests of missions, he being editor of the 'Missionary Herald' for a long term, and corresponding secretary of the American Board of Commissions for Foreign Missions 1821–31.

Evarts, William Maxwell, American lawyer and statesman: b. Boston, Mass., 6 Feb. 1818; d. New York 28 Feb. 1901. He was graduated from Yale in 1837, studied law in the Harvard law school and the office of Daniel Lord of New York, in 1841 was admitted to the bar, and in 1849–53 was assistant district attorney in New York. In 1851 he was successful in the conduct of the prosecution of the Cuban filibusters of the Cleopatra expedition. He was retained in 1857 and 1860 to argue the Lemmon slave case on behalf of the State of New York against Charles O'Conor, council for Virginia. An active and prominent Republican, he made the speech nominating Seward for the Presidency at the Republican national convention in Chicago in 1860, though subsequently moving to make the nomination of Lincoln unanimous. In 1861 he and Horace Greeley (q.v.) were rival candidates before the State legislature for appointment to the senatorship vacated by Seward, newly made secretary of state. As a compromise, Ira Harris was finally appointed. Evarts' legal knowledge was frequently employed in the service of the administration. On behalf of the government he conducted numerous important cases. Among such were that before the Supreme Court to establish the right of the United States during the Civil War to deal with the captured ships as maritime prizes (1862), and that maintaining the unconstitutional character of the State laws taxing United States bonds or stock of the national banks without authorization of Congress (1865–6). He was principal counsel for Andrew Johnson (q.v.) in the President's trial for impeachment, and by his lofty judicial argument contributed much to a result which has since been regarded as most fortunate. He then went into Johnson's cabinet as attorney-general for the remaining year of the term. In 1872 he was chief counsel for the United States before the Geneva tribunal for settlement of the Alabama claims (q.v.). As chief counsel for the Republican party before the electoral commission (q.v.) that settled the Hayes-Tilden Presidential dispute, Evarts based his argument on the constitutional idea that sovereign States must conduct their elections and govern themselves without Federal interference, pointing out that the electoral returns from Louisiana revealed the choice of Hayes electors. During Hayes' administration he was secretary of state. He made, in 1880, a report upon the matter of American control of a trans-isthmian canal, whether at Nicaragua or Panama. His administration of the office was marked by skill in diplomatic questions, the improvement of the consular service, and the publication of consular reports on the economic and commercial status of foreign lands. In 1881 he was a delegate to the international monetary conference at Paris, and in 1885 entered the United States Senate, his term expiring 3 March 1891. He was the senior partner in the law firm of Evarts, Choate, and Beaman, and was frequently retained in important corporation cases. While in the Senate he made several noteworthy speeches, and he also pronounced many distinguished occasional addresses, including the Centennial oration at Philadelphia in 1876.

Eve. See ADAM.

Eve, Paul Fitzsimons, American physician: b. near Augusta, Ga., 27 June 1806; d. Nashville, Tenn., 3 Nov. 1877. He was graduated from the University of Georgia in 1826, and from the medical department of the University of Pennsylvania in 1828; studied also for several years in Europe; and was an ambulance surgeon during the French revolution of 1830, and a regimental surgeon in the Polish war of 1831. In 1832 he became professor of surgery in the Medical College of Georgia; and he obtained a similar chair in Louisville University (Ky.) in 1849 and in Nashville University (Tenn.) in 1850. Made surgeon-general of Tennessee in 1861, he was hospital surgeon on the medical examining board during the War, in 1868 was appointed professor of surgery in the Missouri Medical College (Saint Louis), and in 1870 in the University of Nashville. For a time he was editor of the 'Southern Medical and Surgical Journal,' and assisted in editing the Nashville 'Medical and Surgical Journal.' He published 'Remarkable Cases in Surgery' (1857) and other works.

Evec'tion (Lat. *evectio*, «a turning upward»), the second inequality in the motion of the moon, due to the attraction of the moon by the sun. Owing to the evection the position of the moon may vary 1.25°. It was discovered by Hipparchus nearly 200 years before the Christian era, and more completely determined by Ptolemy.

Eveli'na, a novel published 1778, by Frances Burney. In 'Evelina: or, the History of a Young Lady's Entrance into the World,' Miss Burney, describing the experiences of her heroine in London, gives a vivid picture of the manners and customs of the 18th century. The story is told by letters, principally those of Evelina to her guardian.

Evelyn, ĕv'ē-lĭn, **John,** English writer: b. Wotton, Surrey, 31 Oct. 1620; d. there 27 Feb. 1706. After completing his course at Oxford he began to study law at the Middle Temple. He made some efforts in favor of the royal cause in 1659, on which account he was much favored by Charles II. after his restoration. In 1662 he published 'Sculptura, or the History and Art of Chalcography or Engraving on Copper.' On the foundation of the Royal Society he was nominated one of the first Fellows, and at its meetings he read a discourse on forest-trees, which formed the basis of his most celebrated publication, 'Sylva, or a Discourse of Forest-trees' (1664). He continued in favor at court after the revolution, and was made treasurer of the Greenwich Hospital. He lived for many years at Sayes Court, Deptford, and subsequently succeeded to his brother's estate of Wotton, his life being that of a loyal, worthy, public-spirited country gentleman. Evelyn left a most interesting diary, picturing his life from 1641 to 1706, first published with his correspondence in 1818. A new edition of the 'Diary' was issued in 1827; another, with life, by Wheatley, in 1879.

Evening Grosbeak, a large finch (*Coccothraustes vespertinus*) of western North America. It is olivaceous, with the crown, wings, tail and feet black; forehead and rump yellow; bill yellowish, and a white patch on the wing. It inhabits the forests of northwestern Canada and the Rocky Mountain region, occasionally coming south into the upper Mississippi valley in winter. It has the general habits of its relative, the pine grosbeak (q.v.), and is noted for its rich song.

Evening Primrose, the common name of American plants belonging to the different genera of the natural order *Onagraceæ,* or evening primrose family. They are annual herbs, the yellow flowers opening either during the night or at evening. There are upward of 40 species to which the name is applied, nearly all natives of North America, but many of them naturalized in Europe, particularly in England, where the small-flowered evening primrose (*Onagra cruciata*) formerly *Œnotherabiennis,* is a much prized garden plant.

Evening or **Night Schools,** schools in which instruction is given to pupils debarred, generally by reason of being wage-earners, from the advantages of the day schools. Evening schools arose at a time when compulsory education was not as wide-spread as at present and when more children were consequently growing up without instruction. Beginning with the idea of imparting the more rudimentary branches, such schools have extended their scope until in some cases they form departments of institutions devoted to the study of art, science, or technology. In some of its wider aspects their work has become allied to the university extension movement.

Central Europe.— The evening schools in central Europe are largely the outgrowth of Sunday-schools which shortly after the middle of the 18th century began to add elementary secular instruction to religious teaching. The school age limit being less than at present, a review or continuation of school studies seemed of great importance. In Germany, beginning with lessons in arithmetic and the mother tongue, the range of instruction gradually widened. Some states made attendance obligatory at such Sunday-schools in certain cases. At present the term *Fortbildungsschulen* (literally «further developing schools») is applied in Germany and Switzerland to schools intended for pupils who have passed the elementary school age and yet who study the elementary branches. These *Fortbildungsschulen* are open only in winter and rarely require more than six hours of attendance in the week. Their object is to give boys a practical turn of mind by instruction fitted to bear upon their future callings. They do not furnish instruction in foreign or dead languages or the higher mathematics. In Switzerland, all the 25 cantons have systems of *Fortbildungsschulen* held on Sundays, holidays, and in the evening. The evening schools of France, now numbering many thousands, appear not to date back farther than 1820. The tendency is toward technical training rather than liberal studies, but there are also evening classes or lectures open to those who desire a broader culture.

Great Britain.— In 1806 a benevolent association founded an evening school in Bristol, England, for young persons who were working for a living. In 1811 a school for adults was started in Bala, Wales, and others shortly followed in London and other towns. Such schools were originally supported by private benevolence or local funds, but the government after a time saw the wisdom of aiding them by grants. Since 1861 this aid has been greatly increased, but is not intended to supersede local effort. According to regulations issued by the Board of Education of Great Britain for the school year ending 31 July 1903, local funds are expected to meet 25 per cent of expenditure for the evening schools, and such expenditure must be approved by the board. The schools must not be conducted for private profit. They are under supervision and examination by the board, are subject to its examinations, and must report to it. Schools charging no fees are not generally recognized. Instruction must begin after 4 P.M. or on Saturday after 1 P.M. Students under 12 are not admitted nor those who attend day schools under government inspection (art students being excepted). Not more than 160 hours of instruction may be counted for any student in one year. The courses are as follows: (1) Literary and commercial; (2) art; (3) manual instruction; (4) mathematics and science; (5) home occupations and industries. The last course is largely for girls and includes "home nursing." The boys may take a course in ambulance training, in gardening, etc. Throughout London the evening schools give instruction in gymnastics, and swimming and life-saving methods have been taught to some of the pupils. Evening classes have been held in London at various institutions such as University College, King's College, South Kensington Museum, etc. In the so-called provincial colleges evening classes constitute an important part of the work. Special schools give instruction in commercial branches, courses for women, art, technology, and advanced science. The Education Department of Great Britain reported 28 Feb. 1900 for the evening schools of England and Wales 5,008 schools inspected, 474,563 pupils enrolled and grants equivalent to $914,370.

In Scotland the parliamentary grants for evening schools are administered by the Scotch Education Department, and are used as in England to supplement locally raised funds. The courses of study cover about the same ground. Gaelic is found on the curriculum, and agriculture, horticulture, navigation, military drill, and swimming may all be learned. The evening schools of Ireland are subject to more restrictions and are less flourishing than those of Great Britain.

United States.— The first successful evening schools of the United States began near the middle of the 19th century, although an attempt without permanent results was made in New York in 1834. Boston and other large cities soon followed and evening schools gradually became a recognized part of the common school system. The aims of the pupils in the evening schools being generally very practical and their minds more mature, the methods and subjects of instruction are varied from those of the day schools. Branches relating to commercial and industrial occupations are naturally preferred. Free evening schools for instruction in drawing exist in some cities and drawing is included in the curriculum of some of the regular schools. Evening high schools have become common and in addition to these extensions of the public school system, various important institutions, such as Cooper Union, New York; the Maryland Institute, Baltimore, and the Drexel Institute, Philadelphia, offer evening courses of a highly varied and very valuable character, and of a range resembling that of the day classes. Free lectures also connect such schools with university extension methods. One disadvantage recognized in evening classes for industrial workers, both here and abroad, is the fact that the fatigue consequent upon the physical exertion of the day prevents mental alertness and freshness. The evening schools conducted by the Young Men's Christian Association in the United States instruct 26,000 students. Their finishing certificates are accepted in about 100 institutions of college grade. The Young Men's Christian Association Evening Institute of Boston and the McDonald Educational Institute of Cincinnati, under the same auspices, have night law schools. In the 407 business and commercial schools reporting to the United States Bureau of Education in 1901, there were 20,470 students in evening classes. The evening schools connected with the city school systems of the United States reported in 1901, for cities of over 8,000 inhabitants, a total of 921 schools, 5,115 teachers, and 203,000 pupils, the greatest number of schools (718) being in the nine North Atlantic States, and the smallest number (12) in the nine South Central States and Territories.

Evening Star (also called **Hesperus** and **Vesper**), the name given to any one of the planets seen above the horizon before midnight; especially applied to the planet Venus on account of its brightness. Mars, Jupiter, and Saturn are the other chief evening stars.

Everdingen, ev'er-dĭng-en, **Aldart** or **Allart van**, Dutch landscape painter: b. Alkmaar 1621; d. Amsterdam November 1675. His sea pieces, in which he represents the disturbed elements with great truth to nature, are particularly celebrated. In forest scenes, too, he was a master. He is known also as an able engraver by his plates to 'Renard the Fox.'

Ev'erest, Mount, or **Gaurisankar**, that is, Mountain of the Gods, the highest known mountain in the world, is a peak of the Himalayas, in Nepal. It is 29,012 feet high, or about five and one half miles. It was named in honor of Sir George Everest, an Englishman who for a time was surveyor-general of India.

Ev'erett, Alexander Hill, American diplomatist: b. Boston, Mass., 19 March 1792; d. Canton, China, 29 May 1847. Graduated from Harvard in 1806, he was admitted to the bar, and, after serving as *charge d'affaires* at The Hague, was minister to Spain in 1825–9. He then became editor of the 'North American Review,' and was elected to the State legislature of Massachusetts. In 1840 he was appointed special agent to Cuba, and from 1845 until his death he was a commissioner to China. His work on 'Europe, or a General Survey of the Political Situation of the Principal Powers, with Conjectures on their Future Prospects' (1822) was highly esteemed in its time, and was published in French, Spanish, and German. In 1827 appeared his somewhat similar book on 'America.' Among his other volumes are 'Critical and Miscellaneous Essays' (1st series, 1845; 2nd series, 1847) and 'Poems' (1845). He wrote also biographies of Patrick Henry and Joseph Warren for Sparks' series of 'American Biography.' To the 'North American Review' he contributed a large number of essays. While resident in Cuba he was appointed to the presidency of Jefferson College, but ill health compelled his return north. He was at first a member of the National Republican or Whig party, but later supported Jackson.

Everett, Charles Carroll, American Unitarian clergyman: b. Brunswick, Me., 19 June 1829; d. Cambridge, Mass., 17 Oct. 1900. He was graduated at Bowdoin College; and studied at the University of Berlin. He returned to Bowdoin College, where he was tutor for two years, librarian for five, and professor of modern languages 1855–7. He was ordained pastor of the Independent Unitarian Congregational Church in Bangor, Me., 1859, but resigned in 1869 to become professor of theology in Harvard Divinity School, and was dean of the school from 1879 till his death. Among his published works are: 'The Science of Thought' (1869); 'Religion Before Christianity' (1883); 'Fichte's Science of Knowledge' (1884); 'Poetry, Comedy, and Duty' (1888); 'Ethics for Young People' (1891); and 'The Gospel of Paul' (1893).

Everett, David, American writer: b. Princeton, Mass., 29 March 1770; d. Marietta, Ohio, 21 Dec. 1813. He studied law in Boston, and while there wrote for 'Russell's Gazette' and a literary paper called the 'Nightingale.' He edited the 'Boston Patriot' (1809), and the 'Pilot' (1812). His works include: 'The Rights and Duties of Nations,' an essay; 'Darenzel, or the Persian Patriot,' a tragedy (1800); 'Common Sense in Déshabille, or the Farmer's Monitor.' He wrote the well-known lines beginning —

> You'd scarce expect one of my age
> To speak in public on the stage.

Everett, Edward, American statesman and orator, brother of A. H. Everett (q.v.): b. Dorchester, Mass., 11 April 1794; d. Boston 15 Jan. 1865. Graduated from Harvard in 1811, he pursued studies in divinity, became in 1813 pastor of the Unitarian Church, Brattle Street, Boston, and in 1814 published his 'Defence of Christianity' in reply to the 'Grounds of Christianity Examined' of George B. English. In 1814 he was also chosen to occupy the newly established chair of Greek literature. To qualify himself for the post he went to Europe in 1815 for a course of travel and study. He was for two years at the University of Göttingen, and later sojourned in France, England, Italy and Greece. In 1819 he returned to enter on the duties of his professorship. He became also in 1820 the editor of the 'North American Review,' and in 1820–4 contributed to it about 50 papers. He was elected to Congress in 1824, and by successive re-elections held his seat until 1834. Throughout this period he was a member of the committee on foreign relations, and in the 20th Congress its chairman. He drew either the majority or the minority report of many select committees. In politics he was a National Republican (Whig). He declined a renomination to Congress in 1834. In 1835 he was elected governor of Massachusetts, subsequently was three times re-elected, holding the office for four years, and in 1839 was defeated by a majority of one vote. While in Europe in 1840 he was appointed minister plenipotentiary to England. At a time when there were many points of controversy between England and the United States he was successful in the adjustment of numerous important questions. He declined in 1843 an appointment as commissioner to China, and in 1845 was recalled. In 1846–9 he was president of Harvard, and in 1852 he became secretary of state in Fillmore's cabinet for the last four months of the latter's administration. During this brief term of office he settled several difficult matters. In a diplomatic note he declined the joint proposition of Great Britain and France that the United States should enter a tripartite convention which should guarantee to Spain exclusive possession of Cuba in perpetuity. Before he left the department of state he was elected to the Senate. There he vigorously opposed the Kansas-Nebraska bill for the repeal of the Missouri Compromise. He resigned his seat in May 1854. From 1856 to 1859 he pronounced his well-known lecture on Washington in all on 122 occasions, realizing thereby nearly $60,000, which he turned into the treasury of the Mount Vernon Association for the purchase of Mount Vernon by private subscription. He prepared a collective edition of the orations and speeches of Daniel Webster, with an introductory biographical notice; wrote a life of General Stark for Sparks' 'American Biography'; and prepared for the 'Encyclopædia Britannica,' at the instance of Macaulay, a life of Washington afterwards separately published (1860). In 1860 he reluctantly became a candidate for the Vice-Presidency on the Constitutional-Union, or, as it was sometimes known, the Bell-Everett ticket,— John Bell (q.v.) being the Presidential candidate. The ticket received 39 electoral votes,— those of Kentucky, Tennessee and Virginia. During the Civil War he was a staunch Unionist, but disposed also toward a policy of reconciliation. He delivered the address at the dedication of the national cemetery at Gettysburg, Pa., 19 Nov. 1863, and in the Presidential election of 1864 as an elector-at-large he cast his ballot for Lincoln and Johnson.

His last public appearance was at his Faneuil Hall oration, 9 Jan. 1865, on behalf of the sufferers at Savannah.

Everett was noteworthy in his versatility,— a preacher and theologian, a Greek scholar, an editor and author, orator, diplomat, and statesman. He attracted much attention by his pulpit eloquence. As a Grecian he was thoroughly equipped and gave in his time a considerable stimulus in America to the study of Greek letters, antiquities, and history. His literary productions were carefully wrought and marked by his scholarship; but, through interruptions by other activities, they were limited, so far as published, chiefly to his 'North American' articles and the above-mentioned 'Defence of Christianity.' He did not complete a treatise on public law — a subject he was eminently fitted to expound,— on which he was for some time at work. His utterances in Congress showed him rather the orator than the debater, and while a member of the lower house he stood apart from much of party contention as it there appeared. He took, however, a prominent part in discussion, and, as indicated above, was a most valuable committee member. While he was a foreign minister the general negotiations regarding the northeastern boundary and Oregon difficulties were transferred from him through the appointment by Great Britain of Ashburton as special ambassador, yet many of the points in dispute were left to Everett's skilful adjustment. As representative, secretary, and senator he held to the possibility of saving the Union by compromise on the slavery question, but, the war once begun, he was among the ablest supporters and advisers of the Federal government. It is as an orator that Everett is best known. His addresses were generally written with elaborate care, and were of the Ciceronian type in the knowledge and culture displayed as well as in their finished rhetoric. More fully than any other American orator he combined the resources of learning with the arts of the speaker. He lacked Webster's fire and Phillips' magic, but his manner was always impressive and symmetrical. Even in his own time, however, his oratory did not escape criticism for lack of directness and artificiality, and this charge has frequently been made against it. He may be called the pioneer in the American "lyceum," which long had such a reputation. His 'Orations and Speeches on Various Occasions' were collected in four volumes in 1853-68. Consult also Dana, 'An Address upon the Life and Services of Edward Everett' (1865); 'A Memoir of Edward Everett' (1865); and Whipple's remarks in 'Character and Characteristic Men,' pp. 243-52 (1866).

Everett, Joseph David, English physicist: b. Rushmere, near Ipswich, 11 Sept. 1831. He was educated at Glasgow University; was professor of mathematics King's College, Nova Scotia, 1859-64; assistant in mathematics Glasgow University 1864-7; and professor of natural philosophy in Queen's College, Belfast, Ireland, 1867-97. His scientific career has been a most distinguished one. He took a leading part in the selection and naming of dynamical and electrical units, and drafted a report (1873), the adoption of which originated the C. G. S. system now generally employed. The names "dyne," "erg," and "C. G. S. unit" were introduced at his suggestion. His 'Universal Proportion Table,' published in the 'Philosophical Magazine' (1866), was the first application of the parallel column arrangement for obtaining a slide-rule with very open scale. His English version of M. Privat-Deschanel's 'Traité Elementaire de Physique' (1870-2) was so largely re-written as to be almost an original work. Other of his publications are: 'Centimètre-Gramme-Second System of Units' (1875); 'Elementary Text-Book of Physics' (1877); 'Shorthand for General Use' (1877); 'Vibratory Motion and Sound' (1882); etc.

Ev'erett, William, American educator, youngest son of Edward Everett (q.v.): b. Watertown, Mass., 10 Oct. 1839. From 1870 to 1877 he was assistant professor of Latin at Harvard. He has been master of Adams Academy at Quincy, Mass., 1877-93 and since 1897, and was member of Congress 1893-5. He has preached occasionally in Unitarian churches, and is the author of 'On the Cam' (1865); 'Changing Base' (1868), 'Double Play' (1870), two books for boys; a poem, 'Hesione, or Europe Unchained' (1869); 'School Sermons' (1881); 'Thine, Not Mine'; and many pamphlets on political, literary, and religious subjects.

Everett, Mass., city in Middlesex County, three miles north of Boston; on the Boston & Maine Railway, and with connection by electric surface lines with Lynn, Salem, Chelsea, Boston, and adjacent towns.

Industries, etc.— According to the report of the 12th United States census there were in Everett 168 establishments, with a capital of $6,107,735, employing 2,141 wage-earners at wages amounting to $1,068,987, and having a product valued at $5,038,120. The most important manufactories are a chemical plant, structural iron foundries, steel works, and gas and coke works.

Institutions, Buildings, etc.— There are two public libraries, the Shute Memorial and the Parlin Memorial, and the Whidden Memorial Hospital is also located here.

History, Government, etc.— Everett was settled in 1643, and until 1870 it was a part of Malden. It received its city charter in 1892. Its chief development was in the decade 1890-1900. The government is administered by a mayor, chosen annually, and a municipal council in which members of the lower chamber are elected by wards for one year, those of the upper chamber at large for two years. The more important of the subordinate officials are nominated by the mayor and confirmed by the council; the others are chosen by the council. Pop. (1903) 28,317.

Everett, Wash., city, county-seat of Snohomish County; on Puget Sound; on the Northern P., the Great N., the Everett & M. C. R.R.'s; about 55 miles east by north of Tacoma, and 30 miles north of Seattle. It has an excellent harbor with water communication with the Pacific, and agricultural lands, forests, and valuable mines nearby. Such a combination of natural resources is not common. Everett is the entrepôt of the towns and camps in a rich mining belt. Within a district 36 miles long and 20 miles wide, the Monte Cristo, Great Lake, Silver Creek, Troublesome, Sultan, Stillaguamish, and North Fork district send ores to the great smelter in Everett, and in various ways contribute naturally to the substantial growth of the city. The smelter and refinery plant obtains mineral from all over the Northwest. The city contains railroad shops, flour- and lumber-mills, factories, well-built brick buildings, churches, a theatre, a hospital, graded streets, electric light and motive power, sewers, schoolhouses, newspapers, etc. Its school system is excellent. Everett was settled in 1891, incorporated in 1893. Pop. 12,000.

Everett-Green, Evelyn, English writer: b. London 17 Nov. 1856. She is the daughter of Mary Wood Everett-Green (q.v.). She was educated at Bedford College, London; studied music at the London Academy; and for two years was a nurse in a London hospital. Since 1883 she has devoted herself entirely to writing. Among her many published works the best known are: 'The Last of the Dacres' (1886); 'St. Wynfriths' (1893); 'Dare Lorimer's Heritage' (1892); 'Dominique's Vengeance'; 'Shut In' (1894); 'Over the Sea Wall' (1894); 'Arnold Inglehurst the Preacher' (1895); 'Squib: His Friends' (1896); 'French and English' (1898); 'Odeyne's Marriage' (1899); 'The Heir of Haskett Hall' (1899); 'Monica' (1900); 'After Worcester' (1901); 'For the Faith' (1901); 'Olivia's Experiment' (1901); 'In Fair Granada' (1901); 'Fallen Fortunes' (1902); 'Alwyn Ravendale' (1902); 'Hero of the Highlands' (1903).

Everett-Green, Mary Anne (Wood), English author: b. Sheffield 1818; d. London 1 Nov. 1895. She moved to London in 1841 and for nearly 40 years was employed in the record office as one of the editors of the 'Rolls Series of State Paper Calendars.' The works edited by her include: 'Letters of Royal and Illustrious Ladies of Great Britain' (1846); 'Diary of John Rous' (1856); 'Letters of Henrietta Maria' (1857); 'Life of William Whitingham' (1870). Her only original work was the 'Lives of the Princesses of England from the Norman Conquest' (1850–5).

Everglades. The name given to a vast tract of land and water in the southernmost part of Florida, a region, though under the very eyes of the early pioneers and bordered by our own advanced lines of commerce and travel, as yet practically undiscovered. It is not a marsh, a swamp, nor a stagnant pool; neither land nor water. No white man has yet penetrated it for any great distance, either by boat or on foot, owing to the variance in the depths of the water and the dense tangle of saw-grass, scrub-willow and custard-apple which abound there. The State of Florida is one immense mountain top of limestone formation, covered with a network of pot-holes, varying in size from a few feet to thousands of acres; it has countless lakes of fresh water, fed by springs and subterranean streams, and among these is Lake Okeechobee, named by the Indians, Lake Mayaimi, and now known as the Everglades, an irregular body of water 130 miles north and south, and 70 miles east and west, the altitude of its rim being 12 feet above mean low tide in Biscayne Bay and a little less above the Gulf of Mexico. Over the rocky bottom of this lake lies a layer of muck, formed of alluvial deposit and decayed vegetation, varying in thickness from a few inches to several feet, and in this muck the saw-grass finds its origin, takes root and sometimes grows to a height of 10 feet. This saw-grass is one of the most peculiar and interesting features of the Everglades. Shooting up rapidly, pale green in color, as it goes through the water, fading in the sunlight to a dull golden tint, its blades are tough as bamboo, its edges sharp and jagged as a saw. Toward the western end of the lake it is interwoven with wild myrtle and forms an almost impassable barrier, running through the entire length of the lake, although there are some passages through it, known familiarly to the Seminole, but which are almost impossible to locate by the explorer.

Scattered along the eastern and western edges of the lake are numerous islands, some very small, others hundreds of acres in extent, covered with luxuriant growths of live oaks and bays, interspersed with wild cucumber, lemon, and orange trees. The papaya, the custard-apple, and prickly-ash are of frequent occurrence, and here and there may be seen the cabbage palmetto, the pine, and the rubber-tree.

The first white man to enter this mysterious, silent country was a Spaniard, one Escalente de Fontenada, who, after being shipwrecked in the Strait of Florida, was made captive and slave by the great cacique, Calos, but he has left us only a few meagre details of his experiences during his 17 years of captivity. Frequent expeditions of exploration have been sent out by the United States government to penetrate this wilderness if possible, but all have failed, each bringing the explorers, after days of hardships and privations, to the conclusion that the Everglades, though fascinating in its wildness, is a region to be avoided; a forest of trees, rank undergrowths, and saw-grass, impenetrable and practically valueless; and the lake a mixture of currents which seem to begin without reason, lead nowhere in particular, and generally end in a comparatively still pool, with a labyrinth of passages from which there seems no direct egress.

Animal life in the Everglades is fairly abundant, deer being found on both eastern and western shores, otter are plentiful, alligators and crocodile quite numerous, while the snake is there in large numbers. The Glades were once the breeding place for the egret, the ibis, and the heron, and, while many of them are yet to be found, the plume hunter has made such inroads that all are nearly extinct. The region is almost free of all insects, the constantly moving water affording no breeding-place for insect life. Small flies and gnats are found where the foliage is thick, as in all regions, and at certain seasons of the year the Everglade waters contain an annoying bug called the "alligator flea." Fish abound in the fresh waters, and the terrapin and a flat, soft-shell turtle are quite plentiful.

Probably the most interesting of the denizens of the Everglades are the Seminole Indians, divided into two clans or families, the Muskokis and the Mikasukes, who for hundreds of years have inhabited this section of Florida, defying all attempts to dispossess them, and in 1835, during the Seminole War, killing a large number of troops, under Major Dade, sent against them. A few have been captured and transported, but the majority still live there, having well earned the right to their homes, close to Nature's touch and with that indefinable bond of friendship which gives them access to her solitudes, knowing little of the white man's civilization and caring less. The shores of the streams by which the Glades are entered are covered with the cocoa-plum tree, which also grows about the edge of the Glades, producing a blue fruit on the eastern and a white fruit on the western edge. Wherever the land is sufficiently dry, the coontie-plant, really the Florida arrow-root, grows, and from these the Indian gets his sustenance, extracting flour and starch from the roots.

The physical features of the Everglades are beyond description, beauty and charm blending in a strange, sweet sense of mystery. In dry weather, when the water is low, it is possible to drive into the Glades, but the most beautiful and ideal approach is by water, all the rivers of the Glades finding their way to the sea, some by the rocky channels worn by their own age-long floods, and some through miles of wandering curves, their shores lined with forests of mangrove trees.

Looking into these forests, only the dark waters are to be seen. Ascending, the fresh water of the Glades overcomes the brackish tidal water, and the cocoa-plum takes the place of the mangrove. Still farther up the river, the cocoa-plum gives way to the cypress, and pond lilies are seen, the whole panorama of shifting green,— the lemon-like foliage of the cocoa-plum, the dark olive of the mangrove, and the lighter green of the cypress, enlivened by the sunlight,— making a scene of unique beauty.

In the perspective, when the water is low, the Glades, with its numerous islands and with the tall golden grass, gleaming in the sunshine, waving over a field of silver, ending with a sky-line of blue, has a charm for the eye, unequaled, perhaps, by any other spot in the world, and gives to the sightseer or explorer that subtle impulse and uncontrollable desire to adventure into this never-ending plain of grass and water, never reaching the goal but always seeking for something that lies just beyond the horizon.

The climate of the Everglades is faultless, showing no extremes of heat or cold, nor is it subject to sudden change. There are two seasons in the year, the rainy and dry, the latter including June and September, although light showers may be expected at any season, and in the autumn the humidity is very high. Malaria is seldom heard of, the pure air giving the best assurance of health, and it is small wonder that the ancient explorers spent years here trying to find the "Fountain of Youth."

The title to the Everglades is vested in the trustees of the Internal Improvement Fund of Florida, under patents from the Department of the Interior of the United States, by virtue of an act of Congress of 1850, and they are making efforts to drain the Glades and open it to actual settlers, the cost of reclamation being small compared to the great agricultural value, for once dried it would open up the best sugar lands in the South.

Ev'ergreen, Ala., town, county-seat of Conecuh County; on the Louisville & N. R.R.; about 100 miles northeast of Mobile. An agricultural school and experiment station, and the State Baptist Orphan Asylum are located here. Its mineral springs and agreeable climate make it a winter resort. Pop. 1,305.

Evergreen Isle, a poetical name given to Ireland.

Ev'ergreens, plants that retain their leaves in full verdure throughout the winter till the ensuing spring, when they ultimately fall. It was at one time a common error to suppose that evergreens never part with their leaves. The cause of the belief was that the old leaves do not fall until the young leaves have begun to appear, so that trees of this sort are never wholly without leaves. In warm climates many plants retain their leaves for several years, but no such plants are to be found native to temperate and polar climates. Among the best-known evergreens are most of the trees belonging to the order of the *Coniferæ*, the holly and ivy, box, privet, rhododendron, myrtle, etc.

Ev'erhart, Benjamin Matlack, American botanist: b. West Chester, Pa., 24 April 1818; d. 22 Sept. 1904. After a successful business career in his native town and Charleston, S. C., he retired in 1867, and devoted himself to botanical study, becoming a recognized authority on cryptogamic botany. With J. B. Ellis, of New Jersey, he published in 50 parts a notable work entitled 'The Century of North American Fungi,' describing 5,000 species, many of which were discovered by Everhart. With W. A. Kellerman, professor of botany in Ohio State University, he founded and edited 'The Journal of Mycology,' to which he contributed numerous articles on his specialty. Several new fungi discovered by him have been named after him by his fellow-scientists.

Everlas'ting Flowers, a name applied to certain plants belonging to the natural order *Compositæ*, from the fact that when dried they suffer little change in their appearance. By the French they are called *immortelles*, and this name has been introduced into our own language as applied to wreaths made of such flowers to be placed beside recent graves as emblems of immortality. The plants to which this name is peculiarly applied belong to the genus *Helichrysum*, and are natives of Cape Colony and Australia; but it is also given in America to members of allied genera, such as *Antennaria*, *Gnaphalium*, *Anapalis*, etc. The native women of Australia are fond of decorating their hair with the flowers of *Helichrysum elatum* and *Helichrysum bracteatum*. See AMARANTHUS.

Everlasting Pea, a popular name for plants of the genus *Lathyrus*, of the pea family. In the United States it is applied to the beach pea (*L. maritimus*), because it often blossoms until late in the fall. In England the everlasting pea is *L. latifolis*, a cultivated plant like the sweet pea.

Everts, Orpheus, American physician: b. 18 Dec. 1826. Since 1880 he has been superintendent of the Cincinnati Sanitarium. He has published 'Giles & Co., or Views and Interviews Concerning Civilization' (1878); 'What Shall We Do for the Drunkard' (1882); 'Facts and Fancies' (1896); 'The Cliffords, or Almost Persuaded' (1898).

Evesham, ēvz'ham or ēvz'am, England, a municipal borough and market town in the county of Worcester; on the Avon; 15 miles southeast of Worcester, beautifully situated in the vale of Evesham. It is an ancient place, and was the scene of a battle fought in 1265, which replaced Henry III. on the throne. It had a celebrated abbey, of which a fine tower and some other structures still remain. Market gardening is the chief industry. Pop. (1901) 7,101.

Eviction. See EJECTMENT AND EVICTION.

Evidence. "The word evidence considered in relation to law includes all the legal means which tend to prove or disprove any matter of fact the truth of which is submitted to judicial investigation." (Taylor.) Evidence may be either oral or documentary. Oral evidence is the statements made by witnesses during the trial; and documentary evidence consists of the production of papers, on which is writing, marks, or characters capable of being read, which are submitted during the course of the trial. Oral evidence must in all cases be direct: if it is of something that was seen, by the person who saw it; if of something heard, by the person who heard it; if of an opinion, by the person who holds that opinion; or if the knowledge was acquired in any other manner, by the person who perceived it in that manner. The general rule is that hearsay evidence is not admissible. Documentary evidence may be either primary or secondary. Primary evidence of a document is where the document itself is produced for the inspection of the court. When a document has been executed in counterparts, each counterpart is primary evidence against the party executing it; and where a document has been made by printing or any other means that will ensure an exact reproduction, each copy is primary evidence of the other copies, but none of them is primary evidence of the original. Secondary evidence of a document would be counterparts of the document as against the party who did not execute them, copies made from the original and compared with it, office copies, official copies, and oral evidence of the contents of a document by a person who has een the original. Before secondary evidence will be received the party offering it must show a legal reason why the original is not produced, such as being lost, destroyed, in possession of the adverse party, who refuses to produce it after notice to do so, or when it is a public document, or when it is in a country or place from which it is not permitted to be removed.

Either oral or documentary evidence may be given of any fact in issue or relevant to the issue; and where two facts are so connected, although one fact is and the other fact is not the issue or relevant to the issue, yet evidence of both may be given if that fact will render probable the existence or non-existence of the other fact which is in issue or relevant to the issue.

Admissions are statements made by a party to any proceeding and in reference to that proceeding, and they are admissible against the party making them, but not in his favor. Admissions may also be made by an agent, but to bind the principal they must be made by the agent in his regular course of business or employment. If an admission is made after an agreement has been entered into between the parties not to use it as evidence, it is not admissible, nor is it admissible in evidence made under duress. A confession is a statement made by a person charged with a crime stating or suggesting that he committed that crime. If made voluntarily it is admissible as evidence against him, but if made while the person is under any threat or promise which has been given by a person in authority, it is not admissible. Confessions may be made during the course of the trial, but if the question which produced the confession is an improper one, and after the witness had refused to answer it he had been compelled to do so, it is not a voluntary confession and therefore inadmissible. But if he made no objection to answering the question, it is admissible as a voluntary confession. A witness' opinion is received in evidence when it falls under the head of expert testimony; as, when the question is of some science or art, the opinions of persons specially skilled in that art or science are relevant. Any subject on which special study or experience is necessary to the formation of a correct opinion, is a science or art. The most frequent illustrations are medical and hand-writing experts. Before the testimony of a person called as an expert is received, he must satisfy the court as to his ability to form a correct opinion on the particular subject on which he is to testify. The general rule is that evidence as to a person's character is not admissible unless it is the fact in issue, except in criminal cases, but if a person introduce evidence to show good character, the other side may produce witnesses to show the contrary. All facts should be proved by the best or highest evidence. If a fact can be proved by a written instrument, the writing should be produced, and the party alleging a fact must prove it.

Evidences of Christianity, in favor of its divine origin, may be divided broadly into two great classes, namely, external evidences, or the body of historical testimonies to the Christian revelation; and internal evidences, or arguments drawn from the nature of Christianity itself as exhibited in its teachings and effects.

Among the earlier Christian apologists were Justin Martyr, Minucius Felix, Tertullian, Origen, Arnobius, and Augustine. Their work was continued by the schoolmen during the Middle Ages. In the 16th and 17th centuries the influences of the Renaissance and the Reformation gave rise to a spirit of inquiry and criticism which developed English deism as represented by Herbert and Hobbes in the 17th century, and Collins and Bolingbroke in the 18th. The general position of English deism was the acceptance of the belief in the existence of God, and the profession of natural religion along with opposition to the mysteries and special claims of Christianity. It was in confutation of this position that the great English works on the evidences of Christianity of Butler, Berkeley, and Cudworth were written. In France the new spirit of inquiry was represented by Diderot, D'Holbach, and the encyclopedists, who assailed Christianity mainly on the ground that it was founded on imposture and superstition, and maintained by sacerdotal trickery and hypocrisy. No reply of any great value was produced in the French Church, though in the previous age Pascal in his 'Thoughts' had brought together some of the profoundest considerations yet offered in favor of revealed religion. The 19th century was distinguished by the strongly rationalistic spirit of its criticism. The works of such writers as Strauss, Bauer, and Feuerbach, attempting to eliminate the supernatural and the mysterious in the origin of Christianity, were answered by the works of Neander, Ebrard, and Ullmann on the other side. The historical method of investigation, represented alike by the Hegelian school and the Positivists in philosophy, and by the Evolutionists in science, is the basis of the chief attacks of the present time against the supernatural character of Christianity, the tendency of all being to hold that, while Christianity is the highest and most perfect development to which the religious spirit has yet attained, it differs simply in degree of development from any other religion. Notable among later apologists of Christianity have been Paley ('Natural Theology'), Chalmers ('Natural Theology'), Mansel, Liddon, and others, Lecturers of the Bampton Foundation; in Germany, Luthardt, Ewald, Baumstark, and others. Consult: Hopkins, 'Evidences' (1864); and Fisher, 'Grounds of Theistic and Christian Belief' (1883; revised ed. 1902). See CHRISTIANITY; HIGHER CRITICISM.

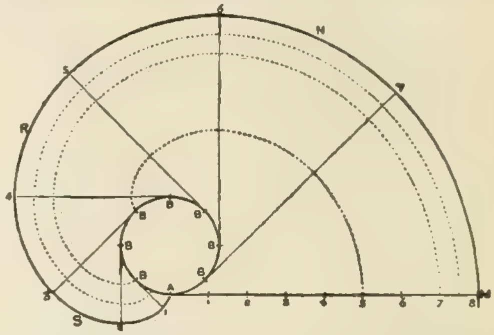
Evil, King's. See SCROFULA.

Evil, Origin of, the subject of extensive theological and philosophical speculation. The difficulty of the question lies mainly in the fact that the existence of evil in the world seems inconsistent with the view that it was created and is maintained by an omnipotent and beneficent creator. The various theories on the subject have all sought to elude this difficulty either by the supposition of some principle of evil equally eternal with that of good, or by regarding evil as having only a relative existence, being a kind of good in an imperfect and immature stage.

Perhaps the oldest theory on this subject is that of Parseeism, or the religion of Zoroaster, according to which there were two original antagonistic principles, one good (Ormazd) and the other evil (Ahriman). This is the doctrine that is now very often spoken of as Manichæism. In contradistinction to this dualistic theory with reference to the origin of evil stand the Monistic theories of Brahmanism and Platonism. According to the Brahmanic doctrine of the emanation of all things from one original being (Brahma), this original being was regarded as the sole true existence, and the phenomenal world, with all the evils appearing in it, was held to be mere illusion. Similarly Plato held that the good was the essence of all things, and that the evil and imperfect contained in them had no real existence. The theory enunciated by Leibnitz in his 'Theodicée' ('Vindication of God') resembles that of Plato. In that work he assigns to the evil existing in the world created by God, which he holds to be the best of all possible worlds, a merely relative existence; all that we call evil is, he holds, only evil to us because we do not see it in relation to the rest of the universe, for in relation to the universe it is not evil but good, and accordingly cannot be evil in its own nature. The traditional Christian account of the origin of evil is that given in Genesis. In the theology based thereon, Satan, the personal principle of evil, differs from the Zoroastrian Ahriman only in not being co-ordinate with the personal principle of good.

Evil Eye. See SUPERSTITION.

Ev'olute, In'volute, in mathematics, correlative terms first applied to the tracing of curves by Huygens, whose discussion of the subject is contained in his 'Horologium Oscillatorium' (1673). Under this distinction every mathematical curve is considered as one of a pair which are mutually produced. This may be explained in the following manner. Around a circular disk wrap closely a thread free at one end and fastened at the other. To the free end



Circle, BBB, as Evolute and its Spiral Involute, MNRSA

attach a lead-pencil. If, now, the string be held taut and unwound from the curve, a second curve will be traced by the pencil. The curve so traced is the involute of the curve whence the string is unwound. The given curve is the evolute of the curve traced. See CURVES.

Evolution, in the natural sciences a term used to denote the process by which an established state of affairs, or system of things, or degree of organization, after persisting for a time, gives rise to another. Thus, we speak of the evolution of the solar system, the evolution of continents, the evolution of plants, the evolution of animals, the evolution of man, the evolution of the brain, and so on endlessly. Evolution expresses the same idea as the term development, but it is convenient in biology to restrict the latter to the growth of the individual (ontogeny), and to keep the former for the growth or history of the race (phylogeny). The fundamental idea of evolution is the essentially simple one, that "the present is the child of the past and the parent of the future"; or, from another point of view, that "there is nothing in the end which was not also in the beginning." More concretely, when we say that the living creatures which we see around us have been evolved, we mean that they are descendants of ancestral forms on the whole simpler, and that these ancestors were descended from still simpler forms, and so on backward — till the scientific imagination loses itself in the mist of life's beginnings. The process of change has been on the whole, as the rock records plainly show, toward increased complexity of structure (differentiation) and toward increased unification and harmonious control of life (integration); but there are many cases of degeneration, both among plants and among animals, where the usual direction of evolution has been in a sense reversed, and where degenerate forms having bcome adapted to parasitic or sedentary or easy-going conditions, are in many respects simpler than their ancestors. In its higher reaches, especially in mankind, evolution has been in great part a progress in psychical integration; but the general idea is the same whether we are dealing with the increasing complication of skeletal architecture in sponges or with the increasing complication of cerebral convolutions in mammals.

Historical.— The evolution idea seems to have been recognized first in relation to human history; thence it was projected upon inanimate and animate nature. One form of institution grows out of another, one race out of another, one language out of another; thus the question arose whether the same may not be true of the order of nature as a whole. Laplace applied the idea in astronomy, and in his famous nebular hypothesis sought to show how the solar system may have been evolved from a simpler antecedent state of affairs. Similarly, Lyell was the most prominent among those who showed that in regard to the configuration of the earth the evolution formula is vividly descriptive. From inanimate nature and human affairs the fertile idea spread like a leaven to the study of fauna and flora and man himself. What Lucretius and much earlier thinkers had dreamed of, what Leibnitz and Schelling and Kant and other philosophers with strong interests in the outer world had sketched in general terms, what Buffon, Erasmus Darwin, Lamarck, Treviranus, Etienne Geoffroy St. Hilaire, Goethe, and others had ventured to promulgate, became through the work of Charles Darwin, Alfred Russel Wallace, Herbert Spencer, and Ernst Haeckel current intellectual coin — the theory of descent. From biology the idea spread to psychology, and the origins of instinctive, intelligent, and rational activities were sought after; finally the idea came home again to its original starting point, as a formula applicable to human history. Already the idea is fast becoming organic in our way of thinking about the origin of all present appearances — whatever be their nature — as a thought economizing formula applicable to all orders of facts.

Analogy of Evolution and Development.— Applied to plants and animals, the suggestion involved in the evolution idea is that the forms now existing are the descendants of relatively simpler ancestors, that they represent, as it were, the tips of many branches which gradually run together as we trace them backward or downward, till they finally unite in a common base — the original forms of life of which nothing is directly known. Moreover, it is implied that the evolution of a race, say of horses or of roses, has been a continuous natural process of slow transformation, just as the individual development of horse or rose-bush is demonstrably a continuous natural process of slow transformation from the apparently simple to the obviously complex. We know as yet but little in regard to the actual factors at work in the marvelous process by which a plant or an animal develops in a few days or weeks or months out of an apparently simple fertilized egg cell; similarly, we know as yet but little in regard to the actual factors which were at work in the marvelous process by which a race of plants or animals, or a particular type, is supposed to have evolved through unthinkably long ages from its apparently simpler presumed ancestors. In neither case has biology advanced far in its analysis of the factors, yet in both cases the majority of biologists would unhesitatingly accept the fact — that a bird grows from an egg by a process of natural development, and that the race of birds has arisen from a reptilian ancestry by a process of natural evolution. But while the development of the bird may be seen taking place, the evolution of the race of birds is hidden in the past; so that we naturally ask for the evidence which has led naturalists to the confident acceptance of the evolution doctrine.

Evidences of Evolution.— The evolution idea has been accepted by naturalists partly because it has proved illuminative in regard to other orders of facts, partly because it has been so useful in promoting and giving point to research, and partly because of certain so-called "evidences" which, though not demonstrative, have nevertheless a cumulative value in establishing a presumption in favor of the interpretation suggested. For it must be clearly recognized that the doctrine of organic evolution does not stand on a secure inductive basis, like for instance the doctrine of the conservation of energy or the theory of gravitation. We are aware of no facts which are contradictory to it, the constant accumulation of new facts brings none to light which it does not fit, but it is a logical error to speak of the doctrine as demonstrated. There is even a slight confusion of thought in speaking of the "evidences of evolution," since all the known facts of life may be construed as part of the evidence. But as there are certain kinds of facts which suggest the evolution idea more forcibly than do others, the nature of these may be indicated.

(a) It is well known that even within the short period covered by careful observation, the forms of life do not remain constant in their characters. Even among forms that are so essentially like one another that they are called by one name — the name of their species — changes are continually occurring. Some of these changes seem to be definitely related to use or disuse or to some alteration in the external conditions (or environment), and we call these modifications or acquired characters. It is very doubtful whether these are transmissible. But there are other changes which begin to appear before or at birth, and cannot be referred directly to changes in function or environment, but seem plausibly due to changes in the germinal material or hereditary substance before or during or after fertilization, and we call these germinal or congenital variations. There is no doubt that these are in varying degrees transmissible, though they may not always be transmitted. By selecting the possessors of suitable variations and causing them to interbreed, cultivators of plants and breeders of animals have in a short time reared many distinct races, as is well known in the case of cabbages and chrysanthemums, pigeons and rabbits, horses and dogs. If man by slight interference can secure these results in a very short time, the inference is suggested that in the enormous time during which living creatures have existed in the earth, proportionately great changes may have been wrought out.

(b) The immense array of plants and animals — living and extinct — that we know can be classified in orderly series. We see various types of organic architecture, bound together by structural affinities, grading into one another, rising one above the other in more and more elaborate complexity and gradually increasing integration. They can be arranged in a scheme of classification, which though still very imperfect may be expressed in the form of a genealogical tree. The suggestion is, that the affinities and gradations on which the classification is based, have a historical meaning, that they express blood relationships, that they point to a descent from common ancestors. Moreover, in a large number of cases the boundaries between what are called distinct species are seen on closer examination to be much less definite and discontinuous than they at first sight appear to be. Species is linked to species by intermediate varieties; genus is linked to genus, and family to family; nor are there wanting synthetic types or "missing links" which help us in imagination to bridge the gulf between distinct types, for example, *Peripatus* between annelid worms and insects, or *Balanoglossus* between some worm-like stock and vertebrates. Remarkable also is the manner in which in distinct groups the same organic material is turned and twisted to diverse results; how, for instance, essentially the same structure of muscle and bone, nerve and blood vessels, is used in vertebrate animals to form the frog's anterior limb, the bird's wing, the horse's fore leg, the whale's flipper, the man's arm, and so on. These homologies or essential similarities in structure and development seem to be most readily interpreted as expressions of a natural descent from common ancestors. Another notable fact is the frequent occurrence of vestigial structures, such as the rudimentary hind limbs of whales, the rudimentary two sets of teeth in the whalebone whales, the visceral clefts in reptiles, birds, and mammals, which are certainly homologous with gill clefts though all possibility of branchial respiration has disappeared. They are only of indirect use, and yet they persist, like, as Darwin said, the unsounded letters in certain words — practically of no direct use — yet giving (here the interpretation comes in) a hint as to the ancestry of the forms which possess them. They are relics of the past, and man himself in this regard carries about with him in his body a museum of antiquities.

(c) Alike in the history of a race as revealed in the geological record, and in the development of the individual organism, which is the problem of embryology, we find numerous facts which suggest, though they do not demonstrate, that the evolution conception is an adequate modal interpretation of the world of life. Thus we have the broad fact that in the history of the earth fishes preceded amphibians; amphibians preceded reptiles, reptiles preceded birds; and many other illustrations show that lower races appeared on the scene before higher ones. It is also possible to work out what are called "palæontological series," in which there is a structural progress in certain stocks, families, or genera, as we pass from later to more recent formations; for example, the series of horse-like mammals, of crocodilian reptiles, of nautiloid cephalopods, of ammonites, and so on through a long list. And again, the rock record discloses extinct types which bridge some of the structural gaps between the living races; thus, *Archæopteryx*, the oldest known bird, helps to link the modern birds to their presumed reptilian ancestry, and the extinct eurypterids lessen the apparent gap which separates the king-crab (*Limulus*) from other jointed-footed or arthropod animals. Not less suggestive is the study of individual development, showing a strikingly gradual progress from the apparently simple to the obviously complex, and an undeniable parallelism between stages in individual growth and grades of organization expressed in the adults of lower forms. It is more rhetorical than scientific to say that an animal in its individual development "climbs up its own genealogical tree," especially since the construction of that hypothetical genealogical tree depends partly on the data furnished by the study of development; but even a brief study of the fortunately preserved stages in the individual growth of fossil cephalopods, or of the familiar circuitous life history of the common frog, shows a parallelism between individual development and racial history which is strongly suggestive of the evolution idea. At the same time, it must be re-emphasized that conviction as to the value of the evolution theory is to be attained, not by a laborious induction, but by its practical justification of itself as a working formula in the study of all orders of facts.

Factors in Organic Evolution.— By the cumulative force of the presumptive evidence we may become convinced that the race of birds evolved from a more ancient reptilian stock, and that the thousands of different kinds of living forms have evolved from a few primitive types, of which we get some hint in *Archæopteryx*, the oldest of the extinct birds. It is quite another matter, however, to profess to understand the precise steps and factors in the process by which "the slow, cold-blooded, scaly beast ever became transformed into the quick, hot-blooded, feathered bird, the joy of creation." The only possible method is to discover the factors which are at present at work in nature, to combine these in a consistent theory, and to test this by applying it to the concrete facts. As it is quite likely that we have not as yet detected all the factors at present operative in producing organic change, and still more likely that we have not succeeded in rightly estimating the relative value of these factors, no completeness can be claimed for the theory of organic evolution in any of its forms. It is also evident that the process of verification which must succeed the process of interpretation will necessarily demand prolonged observation and experiment. The logical possibilities deduced from a study of particular cases, must be shown to be real possibilities for each particular case. Already, however, considerable progress has been made in this respect, and a more stable evolution theory is being gradually evolved.

Originative Factors.— When we compare children with parents, brother with brother, neighbor with neighbor, native with foreigner, but always keeping within the limits of what is called a species, such as the domestic sparrow (*Passer domesticus*), or the edible snail (*Helix pomatia*), or the buttercup (*Ranunculus Ficaria*), we find that the individuals are not by any means always alike in all their characters. We can measure many of the observed differences, and make curves expressing the results. There is no fact more certain than that changes in the structure of plants and animals do occur from generation to generation, and it is in such changes that we must find the raw material of evolution. When the observed differences are studied more carefully, it becomes apparent that a number of them may be directly connected with changes or differences in the surrounding influences or environment, or with changes in the activity or functions of the organism. It is characteristic of these changes that they do not appear till some particular change or difference in the environment or function occurs, and that they are usually exhibited in some measure by all the members of the species who may be subjected to the given environment, or who may exhibit the given change of function. In other words, they can be induced experimentally. It is convenient, as we have already noted, to call these changes "modifications," but they are often referred to under the title "acquired characters." A "modification" is a change in bodily structure which transcends the limits of organic elasticity, which has, that is to say, some persistence, which may, moreover, be correlated with definite changes in environment or in function. To take simple examples; the sun-burning of the skin in a tropical country; the changes in a plant's leaves and flowers when it is transplanted to a quite different habitat; the alterations of even skeletal structure which follow a peculiar occupation or function, like shoemaking; the change of color in a canary's plumage after a special diet; the dwarfing of water snails which are reared in confined space where they have insufficient exercise, etc.; the changes in a brine shrimp's tail induced by altering the salinity of the water, these are all "modifications"— bodily changes which have some measure of persistence. Such "modifications" are often of considerable value to the individuals who acquire them, as may be illustrated by unusual hardening of the skin on positions, like the sole of the foot, which are subjected to unusual influences of pressure, etc., in people who go barefoot. Many naturalists regard these bodily modifications as forming part of the raw material of evolution; but this cannot be the case unless modifications are as such in some degree transmissible to the offspring, and this has not as yet been proved experimentally. Unless the bodily modifications have a specific and representative effect on the germ cells, such that these, when they develop into offspring, will reproduce the modification in some measure, then these modifications, however important in the individual life, are not of direct importance in the racial evolution. It is much too soon to venture on any dogmatic statement on the subject, but as yet no secure evidence of the transmission of acquired characters has been furnished.

Now, when we consider the sum of observed differences, and the sum of what may be proved to be, or may be plausibly regarded as "modifications," we find that the latter do not nearly equal the former. It is necessary, therefore, to seek for some other source of the observed differences, and it is customary to call the residual differences (which remain after subtracting the modifications from the observed differences) by the technical name of "variations," the term being often qualified by such adjectives as "spontaneous," "congenital," "constitutional," "germinal" — all of which refer to the fact that we cannot relate them to differences or changes in environment or in function. These "variations" may appear very early, even before birth; they are exhibited unequally by the members of the species; they are certainly transmissible, though not always transmitted; they are such as may be fairly regarded as forming the raw materials of possible evolution. As to their causes, it is almost premature to speak, but there are several obvious possibilities, none of which is without some basis of fact. Thus (a) the variations may be due to the readjustment brought about in the mingling of hereditary qualities which occurs in the fertilization of the egg cell by the spermatozoon; or (b) they may be due to the influences on the complex germinal material exerted by the variable nutritive conditions within the body, or by the variable environment external to the body. There is no doubt that many diseased conditions have their beginning in a more or less mysterious germinal source; they cannot be ascribed to the direct action of environment or of function on the body; they are congenital, constitutional, innate changes. In some cases, where the rock record is very complete, it is possible to study the variations which occurred in the distant past. Thus, in ammonites and nautiloids, or in gasteropods like *Paludina* and *Planorbis*, the variations which lead on from one species to another have been studied with much success. In most cases, however, the rock record is much too imperfect to admit of this, and it thus becomes of fundamental importance to discover as much as possible in regard to the variations occurring in nature at the present time. For it is only when we have certain knowledge that such and such variations do actually occur now, that we are justified in supposing that similar variations may have occurred in the past. With this study of variation, especially by the use of statistical methods, considerable progress has been made. Thus we know that variations are continually occurring, and that some forms are more variable than others; that the variations can in many cases be registered on symmetrical curves, so that the use of the word "chance," except in its mathematical sense, is inappropriate; that it is common for an organism to vary, not in one particular feature by itself, but in many characters at once, as if it changed as a whole and not piecemeal; that some variations are merely what may be interpreted as due to an incompleteness in the expression of the normal inheritance, while others are new departures; that some variations are very minute, the variant differing from its parent just as one stage of individual growth differs from its antecedent; that other variations imply changes of considerable magnitude, new structural arrangements appearing suddenly and with some measure of completeness, so that they may be said to be "discontinuous" or "transilient," that some variations are disadvantageous and lead on to disease, while others seem from the first useful and adaptive to the conditions of life.

Directive Factors.— As we have seen, the raw material of progress is found in the continual crop of variations, and, according to some, in the continual occurrence of modifications. But as it is not certain that modifications are transmissible, they must at present be left out of the evolution scheme. It has been pointed out, however, that useful modifications may be of indirect importance in evolution by favoring the survival of those organisms which are plastic enough to acquire them till coincident congenital variations in the same direction may have had time to acquire strength and persistence. The adaptive modification acquired by each successive generation afresh, may act as "a screen to perpetuate and develop congenital variations and correlated groups of these." But this requires to be substantiated by concrete instances. Similarly, we require a period of precise observation before we can form a secure judgment in regard to the scope and adequacy of the directive factors of evolution, which are summed up in the terms "natural selection" or "elimination," and "isolation." At present our view must depend on our conclusions as to three debatable subjects: (1) The transmission of modifications or acquired characters; (2) the nature of variations and the proportion of these which are non-adaptive; and (3) the extent to which discriminative elimination occurs in the struggle for existence.

Natural Selection.— The "struggle for existence" is a convenient formula for a certain aspect of animate nature. Most living creatures have a tendency to rapid increase; the results of this often come into conflict with the increase of their means of subsistence, or even with the limitations of space; a further result is the elimination of the many and the survival of the few. In other words, many members of a species have a shorter life, and leave fewer or less successful offspring, than others. The so-called "struggle" — a term which must not be taken too literally — may begin before birth; for example, between the numerous possible egg cells among which only a few may survive, or between the numerous spermatozoa, only a small percentage of which may survive in successful fertilization. And the struggle may, as Darwin said, continue on to the hour of death. There is a second fundamental reason for the struggle, namely, the variability of the physical environment — climate, weather, temperature, illumination, pressure, etc.— to which organisms are at the best only relatively well adapted. On these primary conditions of struggle others depend; for example, that one kind of organism naturally feeds on another, or that there may be a disproportion between the numbers of the sexes, so that all cannot be mated. The struggle may be between the living creature and inanimate nature, between plants and animals, between one race of animals and another, between members of the same species, between rival males, . . . and so on till we come down to the germ cells. The objects, too, are as diverse as the possible parties; they include especially (1) individual existence and well-being; and (2) the continuance of family and kin — both of them objects of great complexity. The degrees of intensity are not less diverse — from life-and-death struggle for bare subsistence to a rivalry in the pursuit of increased pleasure; but the intensity will mainly depend on the rate of reproduction and the variability of the environment. In short, the struggle for existence is a function of numerous, partly dependent, partly independent variables. It is a general technical expression of what occurs whenever the effectiveness of an organic response is of critical moment in relation to continuance and well-being.

The fact of elimination is obvious, the difficulty is to decide how far it is discriminative. The occurrence of a storm may thin the ranks of an overcrowded community, but it cannot be assumed that the survivors do survive in virtue of the possession of particular characters. This has to be proved by careful comparison of the survivors and the eliminated, and it cannot be said that this has yet been done in a sufficient number of cases to give us the security we should wish to have in speaking of discriminate elimination or selection. The task is the more difficult since elimination does not necessarily mean immediate death, but may only mean a shorter or less vigorous life and fewer and less vigorous offspring. It is evident that when the farmer thins the turnip crop with rapid strokes of the hoe, he is for the most part an indiscriminating eliminator, though he may now and again pause to spare a particularly promising plant which happens to catch his eye. The theory of natural selection is based on the assumption (in some cases verified) of discriminate elimination, for the fundamental idea of the theory is that in the struggle for existence those forms are eliminated which are relatively unfit, the survivors being those which are varying in the direction of greater fitness or more perfect adaptation to the particular conditions of their life. It must be borne in mind that by the phrase "survival of the fittest," evolutionists always mean the survival of the fittest relative to given conditions.

Isolation.— It has often been urged as an objection to the Darwinian theory, that particular variations of small amount would tend to be lost or neutralized by intercrossing. In his artificial selection the breeder takes measures to prevent this by isolation, but what is the factor in natural conditions? In answer to this objection, it has been suggested that numerous similar variations may occur at once, for example, under the influence of a similar environmental stimulus. It may also be answered that the experience of breeders and cultivators shows that variations are by no means always readily swamped, even in the absence of isolation. Some new departures have a remarkable potency for persistence even when the conditions do not appear favorable. It is possible to conceive of a struggle for existence within the fertilized ovum, wherein the physical basis, corresponding, let us say, to a strongly marked paternal variation, asserts its "prepotency," and expresses itself in development through succeeding generations even without co-operation from a similar characteristic on the maternal side. But the answer which has been emphasized, especially by Romanes and Gulick, is expressed in the word isolation. Under this term is included a variety of ways in which free intercrossing between members of a species is prevented, for example, by geographical barriers, by changes of habit, by reproductive variations causing mutual sterility or incompatibility between two sections of a species living on a common area, and so on. There can be little doubt that isolation in some of its forms has been an important factor in evolution, but there is still lack of sufficiently precise evidence in regard to the supposed swamping without isolation, and in regard to the general prevention of free intercrossing.

Thus, at the present date, we are led to the conclusion that while the general conception of evoution stands more firmly than ever as a reasonable modal interpretation of organic nature, there is great uncertainty in regard to almost every question concerning the factors in the evolution process. It may also be noted in conclusion that the evolutionist's task is altogether a scientific one, and has in itself nothing whatever to do with ultimate problems. The evolutionist interpretation is not in the slightest degree a philosophy of nature, but an attempt to show how the present may be accounted for in terms of the past by the intrinsic factors observed to be at work. Neither in this nor in any of his tasks does the scientific investigator seek after ultimate explanations. At some point or other he assumes to start with an original institution of the order of nature, in other words a creation, and at no point does he imagine that he is doing more than working out a formula to fit facts.

JOHN FISKE.

Evora, ā'voo-rä (ancient EBORA), Portugal, capital of the province of Alemtejo, 72 miles east of Lisbon. It is a very ancient city; Quintus Sertorius took it in 80 B.C., and it was also conquered by the Moors in 715, but recovered from them in 1139. Among the famous Roman antiquities of Evora are the temple of Diana, with fine Corinthian columns; an aqueduct erected by Quintius Sertorius, and restored in the 16th century, which still supplies the city with water; and the beautiful tower, surrounded by Ionic columns, at the extremity of the aqueduct, and which, although it has existed since 70 B.C., is in almost perfect preservation. It has an archiepiscopal library, containing, besides some 25,000 volumes, several pictures of great merit. There are some manufactures of cotton, cloth, and hats, and a trade in wine. Pop. 15,134.

Evremond, ävr-môṅ. See SAINT EVREMOND.

Evreux, ā-vrė (ancient CIVITAS EBUROVICUM), France, the capital of the department of Eure; on the Iton; 57 miles west by northwest of Paris. It is one of the oldest towns of France, and its ruins and existing ancient Norman buildings show its antiquity. The most noted of the buildings are the Church of Saint Taurin, the bishop's palace, dating back to 1484; the Tour de l'Horloge, built in the same century, is also one of the prominent features of the town. The educational institutions located there include two theological seminaries, a library, a lycée, and a small museum. The history of the town has been of the same tumultuous order as that of many other towns in that section of France, having been taken from the Romans by Clovis; the Normans under Rollo pillaged the town in 892; Henry I. of England captured it in 1119, laying it in waste by fire; Philip Augustus of France took it in 1194 and in 1199; and during the wars of the 15th century between the French and English it was the scene of many bloody conflicts, being passed from the control of one to the other many times. The principal manufactures are hosiery, leather, tiles, and bricks. Pop. (of the commune) 17,113.

Ewald, Georg Heinrich August, gā-ōrg hīn'rĭH ow'goost ā'vält, German Orientalist and biblical critic: b. Göttingen 16 Nov. 1803; d. there 4 May 1875. As a student he published his first critical work, 'Die Composition der Genesis.' He became professor of theology at Göttingen in 1831, and in 1835 professor of Oriental languages. As one of the seven professors of Göttingen who signed the protest against the abrogation by King Ernest Augustus of the Hanoverian constitution, he lost his position, and accepted, in 1838, a call to Tübingen as professor of philosophy. He returned in 1848 to Göttingen, and resumed his old position. When Hanover was annexed by Prussia in 1866 he became a zealous defender of the rights of the ex-king, and this led to his removal from his university chair, though his salary was continued. He was elected several times a member of the diet, where he spoke strongly in favor of the restoration of the Hanoverian monarchy. His 'Kritische Grammatik der hebräischen Sprache' (Critical Grammar of the Hebrew Language) (1827), afterward merged in his 'Ausführliches Lehrbuch der hebräischen Sprache,' and continually enlarged (8th edition, 1870), formed an epoch in the study of Hebrew and placed Ewald in the first rank among scholars. 'Das Hohe Lied Salomos' (The Song of Solomon); 'Die poetischen Bucher des Alten Bundes' (The Poetical Books of the Old Testament); 'Die Propheten des Alten Bundes,' containing a translation and interpretation of all the prophets in chronological order; together with his 'Geschichte des Volks Israel' (History of the People of Israel); and 'Die Alterthümer des Volks Israel' (The Antiquities of the People of Israel), are his principal works on the Old Testament. The 'History of Israel' is considered his greatest work, and, like others of his more important writings, has been translated into English. On the New Testament he wrote, among other works: 'Uebersetzung und Erklärung aller Bücher des Neuen Testaments' (Translation and Explanation of all the Books of the New Testament). Another important work is 'Die Lehre der Bibel von Gott, oder Theologie des Alten und Neuen Bundes' (the Doctrine of the Bible regarding God, or Theology of the Old and New Testaments). He also wrote philological treatises on various eastern languages, and on subjects connected with them, among which may be mentioned works on the Book of Enoch, on Phœnician inscriptions, on Phœnician views regarding the creation of the world, on Arabic Grammar, and 'Linguistic Studies.' From 1849–65 he issued a serial almost entirely written by himself called 'Die Jahrbücher der biblischen Wissenschaft' (Year Books of Biblical Science).

Ewald, ā'väld, **Herman Frederik,** Danish novelist: b. Copenhagen 13 Dec. 1821. The most noteworthy of his novels are: 'Valdemar Krone: Story of His Youth' (1860); 'The Nordby Family' (1862); 'Johannes Falk' (1865); 'Charles Lyng,' a fine character study. He also wrote several historical novels popular both in the original and in German translations: 'The Swedes at Kronborg' (1867); 'Agathe' (1873); 'Knud Gyldenstjerne' (1875); 'Anna Hardenberg' (1880); 'The Queen's Maidens' (1885); 'Griffenfeld' (1888); 'Clara Bille' (1892).

Ewald, or **Evald, Johannes,** yō-hän'nĕs, Danish poet: b. Copenhagen 18 Nov. 1743; d. there 17 March 1781. At 15 he ran away and enlisted in the Prussian service. Being compelled to join a regiment of artillery at Magdeburg, instead of being attached to the hussars as he had been promised, he deserted the Prussian standard in the Seven Years' war, and entered the Austrian service. After a few months he returned home and began to apply himself seriously to theology. On the death of Frederick V. of Denmark he was requested to compose an elegy (1766); and the general admiration with which it was received roused his ambition and he soon became one of the most eminent lyric and tragic poets of his nation. His opera the 'Death of Balder' (1774), the subject of which is taken from the northern mythology, and his 'Rolf Krage' (1770), a tragedy taken from the ancient history of Denmark, are works which, notwithstanding many defects, bear the impress of true genius; but by some his lyrical drama 'The Fishers' (1779) is ranked as the finest of all his works. As a lyric poet he is most popular at the present day, and several of his odes and elegies are among the best that modern times have produced. Consult Jorgensen, 'Johannes Ewald' (1888).

Ewart, James Cossar, British zoologist: b. Penicuik, near Edinburgh, 26 Nov. 1851. He was educated at Edinburgh University, where he graduated M.D., and was appointed demonstrator of anatomy 1874. In 1875 he became conservator of the museum, University College, London; in 1878 professor of natural history, Aberdeen University; and in 1882 professor of the same, Edinburgh University, when he was also appointed member of the Scottish Fishery Board. In London he made researches into the bacillus of splenic fever, etc., and at Aberdeen founded the first marine laboratory in Britain, where, with the late Dr. Romanes, he made researches into the locomotor system of the echinoderms, which was the subject of the Croonian lecture of the Royal Society 1881. He conducts the fishery investigations into the fertilization and life history of the herring, whitebait, and other food-fishes, and directs a large corps of assistants in the work at various stations. He established lectureships in his university in embryology and the philosophy of natural history, and organized, for the students, a union. At Penicuik he has conducted the costly experiments, with which his name is widely known, into the development of the horse, and hybridizing of equine species, including the quagga, zebra, and island pony, in different ways; and disproved the hoary theory as to the influence of previous impregnation (telegony). Among his publications are: 'The Electric Organs of Skate' (1888–9); 'The Cranial Nerves and Lateral Sense Organs of Elasmobranchs' (1889); 'The Development of the Horse' (1894); 'Telegony and Reversion' (1887); 'A Critical Period in the Development of the Horse' (1889); 'Guide to Hybrids' (1900).

Ewbank, ū'bank, **Thomas,** American scientist: b. England 11 March 1792; d. New York 16 Sept. 1870. He came to America about 1819 and engaged in manufacturing (1820–36). He was United States commissioner of patents 1849–52. His publications include: 'The World a Workshop, or the Physical Relation of Man to the Earth' (1855); 'Life in Brazil,' with an appendix on a collection of American antiquities (1857); 'Reminiscences in the Patent Office' (1859); 'Thoughts on Matter and Force' (1858); and 'Inorganic Forces Ordained to Supersede Human Slavery,' an essay.

Ewell, ū'ĕl, **Alice Maude,** American novelist: b. Prince William County, Va., 7 Nov. 1860. She has published 'A White Guard to Satan,' an historical novel (1900).

Ewell, Benjamin Stoddert, American educator: b. Washington, D. C., 10 June 1810; d. James City, Va., 19 June 1894. He was graduated at West Point 1832, taught mathematics there until 1836, and later served as assistant engineer of the Baltimore & Susquehanna Railroad, becoming professor of mathematics at Hampden-Sidney College 1839, where he remained till 1846. He filled a similar chair at Washington University, Lexington, Va., 1846–8, when he went in the same capacity to William and Mary College, becoming its president 1854, and president emeritus 1888. He was in command of the 32nd Regiment, Virginia Volunteers, from 1861–2, and adjutant-general of the Confederate army on the staff of Gen. Joseph E. Johnston, when he was commander of the departments of Tennessee and Mississippi 1862–4.

Ewell, Marshall Davis, American lawyer: b. Oxford, Mich., 18 Aug. 1844. He was graduated at the University of Michigan Law School (1868), and was professor of common law in the Union College of Law, Chicago, from 1877 until the founding of the Kent College of Law, in which he became professor of international law, dean, and president. He is well known as a microscopist, and was elected a Fellow of the Royal Microscopical Society of London (1886), and president of the American Microscopical Society (1893). He has edited: 'Blackwell on Tax Titles' (1875); 'Illinois Reports' (Vols. XXXII.-XXXVI. inclusive, 1877); 'Washburn's Manual of Criminal Law' (1878); 'Evans on Agency' (1879); 'Lindley on Partnership' (1881); and written: 'Leading Cases in Disabilities' (1876); 'Treatise on the Law of Fixtures' (1877); 'Essentials of the Law' (1882); 'Student's Manual of Medical Jurisprudence' (1887).

Ewell, Richard Stoddert, American soldier: b. Georgetown, D. C., 8 Feb. 1817; d. Springfield, Tenn., 25 Jan. 1872. He was graduated at the United States Military Academy in 1840, and served during the Mexican war with Scott from Vera Cruz to the City of Mexico. At the outbreak of the Civil War he resigned his commission in the National army; joined the Confederates; was actively engaged throughout the war and attained the rank of lieutenant-general. He was at the battles of the first and second Manassas, where he lost a leg, Front Royal, Cross Keys, Port Republic, and Cedar Mountain; and was later placed in command of the Second Corps of Gen. Lee's army, upon the death of "Stonewall" Jackson. In this capacity he was in personal command and led the charges of the corps at the capture of Winchester at Gettysburg, the Wilderness, and Spottsylvania Court House, but was transferred to the Department of Richmond after these engagements, owing to his inability to withstand the hardships of another campaign, on account of his wounds. He was later captured at Sailor's Creek. After the war he retired to private life.

Ewer, ū'ėr, **Ferdinand Cartwright,** American Episcopal clergyman: b. Nantucket, Mass., 22 May 1826; d. Montreal, Canada, 10 Oct. 1883. He was graduated at Harvard 1848. After several years devoted to journalism he entered the Episcopal ministry and became rector of Grace Church, San Francisco, 1858. In 1862 he was chosen rector of Christ Church, New York, but his introduction of ceremonies and practices not usual in Episcopal churches caused so much opposition that he resigned 1871. Some friends organized for him the parish of St. Ignatius, New York, of which he continued rector till his death. He was an able controversialist, and wrote: 'Two Eventful Nights, or the Fallacies of Spiritualism Exposed' (1856); 'Sermons on the Failure of Protestantism' (1869); 'Catholicity in its Relations to Protestantism and Romanism' (1878); 'The Operation of the Holy Spirit' (1880); 'Grammar of Theology' (1880).

Ewers, ū'ērz, **Ezra P.,** American military officer: b. New York. He entered the army in January 1862, and after successive promotions was commissioned brigadier-general of volunteers in December 1898; and placed in command of troops in San Luis, Cuba. During the Civil War he distinguished himself at Hoover's Gap and in the battle of Chattanooga, and was brevetted major, 27 Feb. 1890, for gallantry in action against the Indians under Crazy Horse, Tongue River, Montana, 8 Jan. 1877.

Ewing, ū'ing, **Emma Pike,** American educator: b. Broome County, N. Y., July 1838. She was married to W. P. Ewing in 1863. Since 1880 she has been prominent as a teacher of and lecturer on cookery and domestic economy. She conducted a school of cooking in Chicago (1880–3); was professor of domestic economy, Iowa Agricultural College (1883–7), and Purdue University (1887–9). She has also been dean of the Chautauqua Assembly Cooking School (1882–99), and director of the model school of household economics in connection with Marietta College, Ohio (1898). She has published: 'Cooking and Castle Building' (1880); 'The Art of Cookery' (1897); 'Cookery Manuals' (1884); 'Text-books of Cookery' (1898).

Ewing, Hugh Boyle, American soldier: b. Lancaster, Ohio, 31 Oct. 1826; d. there 30 June 1905. He was educated at the United States Military Academy; in 1849 went to California in charge of an expedition sent out by his father, then Secretary of the Interior, to rescue emigrants from the snowbound Sierras, whence he returned in 1852; practised law in St. Louis 1854–6, and in Leavenworth, Kan., 1856–8. He served through the Civil War, becoming a brevet major-general; was United States minister to The Hague 1866–70, and wrote: 'A Castle in the Air' (1887); 'The Black List' (1893); etc.

Ewing, James Alfred, Scotch engineer: b. Dundee 27 March 1855. From early childhood his mind was bent on the study of scientific subjects, especially mechanical engineering, and after receiving an elementary education at the Dundee High School, he took a course of scientific studies at the University of Edinburgh. For several years until 1878 he was assistant in telegraph engineering, in which year he was appointed to the chair of mechanical engineering at the University of Tokyo, Japan. During his term of five years as instructor there he did much important work in measuring the vibrations of the earth during an earthquake by means of instruments of his own invention. So entirely new, original, and exhaustive were these investigations that in 1883 the university published them under the name 'Earthquake Measurement'; the Seismological Society of Japan also published some of the results of his researches. In 1883 he returned to Dundee, where he became professor of engineering in University College; in 1890 accepting the professorship of applied mechanics at Cambridge. He has published: 'Magnetic Induction in Iron and Other Metals' (1892); 'The Steam Engine and Other Heat Engines' (1894); 'The Strength of Materials' (1899); etc.

Ewing, John, American Presbyterian minister and mathematician: b. Nottingham, Md., 22 June 1732; d. Philadelphia, Pa., 8 Sept. 1802. As a youth he exhibited marked ability in mathematics and later took a course of study in Princeton College, where in his senior year he also acted as a tutor in the grammar school. Upon graduating in 1755 he was appointed instructor in the college. He then became interested in theology and after finishing his course in divinity was licensed to preach by the presbytery of Newcastle, Del. In 1758 he received his appointment as instructor of the philosophical department in the College of Philadelphia and in 1759 became pastor of the first Presbyterian church in that city, remaining such until 1773 when he was sent to England to solicit pecuniary aid in the establishment of an academy. In 1775 he returned to his native land, and in 1779, when the College of Philadelphia was changed to the University of Pennsylvania, he was placed in the station of provost, and officiated in that capacity until his death. He was elected to the vice-presidency of the American Philosophical Society and contributed many valuable articles to its 'Transactions.' He also contributed many articles on astronomical subjects to the American edition of the 'Encyclopædia Britannica.' He was also selected to serve on the commission to establish the Delaware State boundary line, and also to settle the boundary lines between Massachusetts and Connecticut, and Pennsylvania and Virginia. His 'Lectures on Natural Philosophy' (2 vols. 1809), and a collection of sermons were published after his death.

Ewing, Juliana Horatia Gatty, English writer for young people: b. Ecclesfield, Yorkshire, 1841; d. Bath, Somerset, 13 May 1885. She contributed largely to a magazine started by Mrs. Gatty, her mother. On her mother's death the magazine was edited by her and her sister conjointly, and many of her best stories first appeared in it. Of her delightful tales of child-life we may mention: 'Mrs. Over-the-Way's Remembrances' (1869); 'The Brownies' (1870); 'A Flat-iron for a Farthing' (1873); 'Lob-lie-by-the-Fire' (1874); 'Six to Sixteen'; 'Jan of the Windmill' (1876); 'A Great Emergency' (1877); 'We and the World' (1881); 'Old Fashioned Fairy Tales'; 'Brothers of Pity' (1882); 'The Doll's Wash'; 'Master Fritz'; 'Our Garden'; 'A Soldier's Children'; 'Three Little Nest Birds'; 'A Week Spent in a Glass House'; 'A Sweet Little Dear'; and 'Blue Red' (1883); and 'Jackanapes' (1884). A biography by her sister, Horatia K. T. Gatty, was published in 1885 under the title 'Juliana Horatia Ewing and Her Books.'

Ewing, Thomas, American statesman: b. near West Liberty, Va., 28 Dec. 1789; d. Lancaster, Ohio, 26 Oct. 1871. He was graduated at the Ohio University in Athens in 1815; admitted to the bar in 1816; and practised law for 15 years. He was a United States senator from Ohio 1831–7 and 1850–1; secretary of the treasury under President Harrison in 1841; and secretary of the interior under President Taylor in 1849. In the United States Supreme Court he ranked among the foremost lawyers of the nation. During the Civil War his judgment in matters of state was frequently sought by President Lincoln. When the capture of Mason and Slidell brought England and the United States to the very point of hostilities, Ewing sent the famous telegram that was really decisive of the whole trouble: "There can be no contraband of war between neutral ports" — and it was his advice that finally prevailed over Everett's opinion, and the envoys were set free.

Ex Parte, ĕks par'tē (Lat. "from a part"), a law Latin term used in reference to an action taken by either party to a suit or other legal proceeding, or on behalf of such party, without notice to the other. Ex parte evidence or hearings are frequently made use of without being regarded as an infringement of the rights of the opponent. In a derived sense the term indicates a lack of accuracy or impartiality in a statement.

Ex Post Facto (eks pōst făk tō) **Law** (Lat. "from what is done afterward"), one made after an offense and taking effect retroactively. The provision in the Constitution of the United States, Art. I., sec. 9, clause 3, that "no . . . ex post facto law shall be passed," has been interpreted to refer only to crimes, and in that sense the words are commonly used. The following have been decided to come within the scope of the phrase: Every law that makes an action done before its passage, and innocent when done, criminal, and punishes such action; every law that aggravates a crime, or makes it greater than when committed; every law that changes the nature of the punishment, or makes it greater than at the time the act was committed; every law that alters the rules of evidence so as to make it easier to convict the offender; every law that, while not avowedly relating to crimes, in effect imposes a penalty or the deprivation of a right; every law that deprives persons accused of crime of some lawful protection to which they have become entitled, as a former acquittal. Such laws are therefore contrary to the Constitution. Consult: Cooley, 'General Principles of Constitutional Law in the United States' (3d ed. 1900).

Exactions (from Lat. *exactio,* act of driving out, forcing out, a forced contribution), a legal term of ecclesiastical jurisprudence, used in the Middle Ages to denote such duties or contributions, demanded by the clergy of their parishioners, as were extraordinary, either because they were new and against custom or because their amount was unduly increased. They were illicit, and it was found necessary repeatedly to denounce their unlawfulness. The power of the clergy over their parishioners, or of the bishops over the subordinate clergy was so great that it was easy for them to make the most outrageous exactions. In 589 the third Council of Toledo forbade the bishops *exactiones diociesi vel damna infligare,* and the meaning of this is more exactly defined by Leo IV., who, in 853, forbade the bishops to exact from the clergy and ecclesiastical institutions of their dioceses "dationes ultra statuta patrum aut super appositæ in angariis." Yet, in 1179, Alexander III. found it necessary to repeat: "Prohibemus ne ab abbatibus vel episcopis, aliisve prælatis novi census imponantur ecclesiis, nec veteres augeantur nec partum redituum suis usibus appropriare præsumant."

Examiners, Medical, in some States, as Massachusetts and New York, county officials whose duties are practically those formerly discharged by coroners, whom they have superseded. See CORONER.

Exanthemata, ĕk-săn-thē'ma-ta, a name formerly widely employed to designate the acute infectious diseases that were characterized by an eruption — the eruptive fevers. The most important of these are measles, scarlet fever, chickenpox, smallpox, typhoid fever, and typhus fever (qq.v.).

Exarch, ĕks'ärk (Gr. ἔξαρχος, *exarchos,* leader), a title equivalent to governor (Lat. *rector*), in the terminology of civil government after the seat of empire was transferred to Constantinople. But already in the 4th century it acquired the signification of archbishop, metropolitan, or patriarch. In the acts of the first Council of Constantinople (381) the bishops of Alexandria, Antioch and Constantinople are styled exarchs; and the field of jurisdiction of an exarchos is exarchia. In the same period exarchos, exarchia were in use as designations of civil magistrates and their jurisdictions, the term diocese (διοίκησις, *diôecesis*) was also used. In ecclesiastical usage exarch came in time to be a title of honor apart from jurisdiction; thus, by the Council of Chalcedon (451) the bishops of Ephesus, Heraclea and Cappadocian Cæsarea, though deprived of their jurisdiction over the metropolitans previously suffragan to them, were permitted to be called by the title exarch.

Exauvilliez, Philippe Irenet Boistel D', fē-lēp ē-rē-nā bwäs-tĕl dĕks-ō-vē-ē-ā, French author: b. Amiens 6 Dec. 1786; d. 1858. His essay, 'The St. Gervais Library' (1831), gave the first impulse to the establishment of small libraries all over France. He translated Walter Scott's novels, from which he eliminated every passage which could be interpreted as telling against the Roman Catholic religion, and also all love passages as far as possible.

Excal'ibur, the famous mystic sword of King Arthur (q.v.) which, in accordance with the promise of Merlin, was given him by the Lady of the Lake. At Arthur's death it was hurled by Sir Bedivere into the lake, where it was seized and conveyed from sight by a mysterious hand. Consult: Tennyson, 'Idylls of the King.'

Ex-cath'edra (Lat. "from out the chair"): a phrase originally applied to decisions given by popes or prelates in a solemn judicial manner. Hence it is applied to every decision pronounced by any one in the exercise of his proper authority, as judge on the bench, etc.

Excavator, a machine for digging, moving, and transporting gravel, soil, etc. Excavators are made of two kinds, each adapted for different kinds of work. In making a long cutting, the first to come into operation is operated on rails, and employs a large «scoop» or bucket, with a lever heavy enough to counterbalance the bucket when filled with clay. The scoop is lowered and driven into the bank until full. It is then raised by the suspension chain, and dumped by the chain on the lever. The second class of excavator is employed to make the cutting wider. Its sides are made sloping to an angle of 45°, and on the top of the bank a temporary line of rails is laid a few feet from the edge. The machine is placed on the rails at the end of the cutting; the jib is lowered until the row of buckets it carries can cut into the clay; these scrape up the bank, reaching the top of it full of soil; they next pass over the machine, and are emptied into the wagons beyond it.

Excellency (from Lat. *excellentia*, superiority) a title of honor given to ambassadors, governors of British colonies, and the governor of Massachusetts. The President of the United States and the governors of many of the States have the same title by courtesy. In former times it was applied only to sovereign princes.

Excelmans, ěk-sěl-män, or **Exelmans, Rémi Joseph Isidore**, rā-mē zhō'zěf ē-sē-dōr, Baron, French marshal: b. Bar-le-duc 13 Nov. 1775; d. 10 July 1852. He entered the army in 1791, served with distinction at Austerlitz in 1805, and gained the rank of general of brigade for his conduct at Eylau in 1807. In the Russian campaign (1812) he commanded a division. He directed a corps at the battle of Waterloo, after which he passed four years in exile; was restored to his title as a peer in 1831, and became a marshal of France in 1851.

Excel'sior (Lat. «higher») (1) the motto of New York State. (2) A well-known poem by H. W. Longfellow, published in 1841, of which the opening words are: «The shades of night were falling fast.» The poem in its musical setting became in America a favorite academic song.

Excelsior, the trade name of a material invented in America and widely used for packing and as stuffing in mattresses and upholstery. It is made from logs of wood which have first been divided into 18 inch blocks. The fibres are separated from the blocks with great rapidity by knife-points, and packed in bales of 250 pounds weight. Not far from 45,000 tons are annually manufactured in the United States, and of this output large quantities are exported.

Excelsior Geyser, a geyser in the Yellowstone National Park, and one of the largest in the world. It has thrown a column of water to a height of 200 to 300 feet. See Yellowstone National Park.

Exchange, the act of exchanging or giving one thing for another. The term also signifies that which is so given. In commerce it is applied to a place where merchants, brokers, etc., meet to transact business; it is generally contracted into 'Change. The institution of the modern exchange dates from the 16th century. They originated in the important trading cities of Italy, Germany, and the Netherlands, from which last-named country they were introduced into England. The most celebrated are the Royal Exchange of London, the *Bourses* of Paris and Amsterdam, the Börse of Hamburg, and the New York Stock Exchange in Wall Street. In some exchanges only a special class of business is transacted. Thus there are stock exchanges, corn exchanges, coal exchanges, cotton exchanges, etc. For Bill of Exchange, see Bill.

Course of Exchange is the current price of a bill of exchange at any one place as compared with what it is at another. If for $500 at one place exactly $500 at the other must be paid, then the course of exchange between the two places is at par; if more must be paid at the second place, then it is above par at the other; if less, it is below it. *Arbitration of exchange* signifies the operation of converting the currency of any country into that of a second one by means of other currencies intervening between the two. In arithmetic *exchange* is a rule for ascertaining how much of the money of one country is equivalent in value to a given amount of that of another. In law, a mutual grant of equal interests, in consideration the one for the other is termed *exchange*. In physics the *theory of exchange* is a hypothesis with regard to radiant heat, devised by Prevost of Geneva, and since generally accepted. All bodies radiate heat. If two of different temperatures be placed near each other, each will radiate heat to the other, but the one higher in temperature will receive less than it emits. Finally, both will be of the same temperature, each receiving from the other precisely as much heat as it sends it in return. This scale is called the mobile equilibrium of temperature.

Exchange, an association providing an organized market for transactions in stocks or commodities. Thus a stock exchange deals in the shares or certificates of indebtedness of stock companies, a cotton exchange in cotton, and a produce exchange in grain and provisions. The rules of these exchanges establish a system by which stocks or commodities may be traded in either for investment or speculation; for immediate or future delivery; for cash, that is, payment in full, or to be carried on margin or security representing a certain percentage of the value of the stocks or commodities purchased. This system enables the trader or operator to be either long or short, to buy what he may not have the means to pay for in full, in hopes that he may sell at a profit on rising prices; or else to sell what he does not own, but is able to borrow in order to make delivery, the desire being that prices will decline so that he can buy at a profit, thus returning what he has borrowed.

There are stock exchanges in nearly every leading city of Europe and America, the London Stock Exchange, the Paris Bourse, and the New York Stock Exchange being, by far, the most important, their transactions leading all others in magnitude and scope. In the United States there are stock exchanges in Philadelphia, Boston, Chicago, Pittsburg, Baltimore, Cleveland, Cincinnati, Detroit, New Orleans, Denver, Indianapolis, San Francisco, Washington, Kansas City, Los Angeles, Providence, and Richmond. In Canada there are stock exchanges in Montreal and Toronto. Mining stock exchanges exist in Colorado Springs and Cripple Creek. The principal cotton exchanges are at New Orleans, New York, and Liverpool. The Chicago Board of Trade and the New York Produce Exchange are the leading markets for grain. There are prosperous coffee exchanges in New York and Hamburg. In New York be sides the Stock Exchange, there is a rival institution, called the Consolidated Stock & Petroleum Exchange, where there are dealings in stocks, oil, and other commodities. New York also contains, in addition to these two stock exchanges and the Produce, Cotton, and Coffee exchanges, a Maritime Exchange and a Metal Exchange. Chambers of Commerce and Boards of Trade may also be exchanges. For instance the Chicago Board of Trade is the controlling market for grain. But commonly they are not; and the Chamber of Commerce, and the Board of Trade and Transportation, in New York, are in no sense of the word exchanges, no buying or selling taking place within them. They are simply associations of business men for the promotion of commerce and its protection against adverse legislation.

Exchanges are an evolution of modern business. It was not until late in the Middle Ages that anything like the exchanges as they exist to-day were established. At first these were associations of merchants and bankers. The stock exchange is a product of the 18th century, and the produce and cotton exchanges of the 19th century, the system of option trading being a creation of the past 40 years. The Paris Bourse was founded in 1726, and the London Stock Exchange in 1773. The first stock exchange in the United States was founded early in the 19th century in Philadelphia. The New York Stock Exchange was organized in 1817, but the stock brokers had even then been working, for 25 years, under an agreement as to commissions, this agreement having been entered into as early as 17 May 1792. The merchants had a meeting place or exchange on Broad Street near Pearl in 1752. Sixteen years later the Chamber of Commerce was organized. The Tontine Coffee House built in 1794 was for many years the principal market place of the merchants, bankers and brokers of New York.

It is usual for the exchanges and the principal banks to be located in one quarter of the city and this quarter thus becomes the financial centre. In London the Bank of England and the principal banking houses and the stock exchange are located in Threadneedle, Throgmorton, and Lombard streets and Capel Court. In New York the financial district centres in Wall Street; which is a short narrow street reaching from Broadway to the East River. In this street are the Custom House (soon, however, to be moved to Bowling Green), the sub-treasury, the assay office, and many of the banks and trust companies. The financial district has, however, outgrown the narrow area of Wall Street, and takes in Broad, New, William, Nassau, and Beaver streets, and Exchange Place. But still the term «Wall Street» is commonly applied to the entire financial district, in which are located seven exchanges, the sub-treasury, 35 banks, 29 trust companies, and the general offices of fully 500 great railroad, insurance, express, telegraph, mining, industrial, and manufacturing corporations as well as of several thousand brokers. Many of the brokers are members of several exchanges, and there are close business relations between the banks, the exchanges, and the corporations.

Wall Street is not only the financial centre of America, but it is second only to London in the extent and volume of its transactions. Indeed the transactions of its clearing house now exceed those of the London Clearing House. Prof. Bryce in his 'American Commonwealth' says that the operations of Wall Street are vaster, more boldly conceived and executed with a steadier precision than those of European speculators. There are many and marked differences between the London and the New York Stock Exchange systems. These differences are, however, not essential. Both lead to the same result, though by different ways. Moreover both have a common origin in the natural desire of men to invest their surplus earnings in such a manner as to yield the utmost income possible with the largest safety. Formerly, all investments were practically limited to land, but the area of real estate investments is necessarily restricted, and moreover land, in order to be made to yield a profit, must be developed and tilled. This involves labor for which the merchant and professional man have no time or skill. But in the 17th century a new field for investments was opened. In the first years of that century the East India and Hudson Bay companies were formed and toward its close their shares began to be actively traded in. Stocks were thus added to land as objects of investment, and it is of interest to note that it was the shares of trading and promoting companies which formed the basis of the first stock market. For many years past the shares of transportation companies have been the chief objects of speculative interest, but recently the industrial and trading companies, as in the first years of the stock market, are becoming the most active.

Macaulay, in his history of England, gives a brief but graphic account of the beginnings of the London stock market. The step from investment to speculation was easy, and an extraordinary demand for stocks set in, which was met by the creation of many new companies, modeled on the East India and Hudson Bay companies, and as might be expected, many of these new corporations were bogus concerns, the offspring of criminal promotion. Early in the 18th century a remarkable speculation set in in the shares of the South Sea Company in England and of John Law's Mississippi Company in France. When these speculative bubbles burst, the inevitable panic followed, quickly made fortunes were wiped out, and persons who had invested their all, suddenly found themselves penniless. Many were forced into bankruptcy, and loss and distress were widespread.

For upward of a century the stock market of England existed on the curbstones and in the coffee houses of 'Change Alley. It was without habitation or name, or organization, and yet the business transacted was often of immense volume, and most of the terms of speculation, the slang of the market, were coined at that time. At length the need of organization became apparent and the London Stock Exchange was formed.

There was much the same evolution in America although, of course, it came later, and at first on a much smaller scale. The evolution began after the close of the long war for independence. The national government assumed the war debts of the States and the first Congress issued bonds to take these up. Banks were organized. Investments in these bonds and the shares of these banks were made by those people whose incomes were larger than their expenditures. Out of this demand for investment, speculation soon developed, and under a buttonwood tree, near 68 Wall Street, a number of stock brokers began to assemble every day to buy and sell the few then existing securities. As has been said they entered into an agreement, establishing regular rates of commission. For a quarter of a century the stock market thus existed on the Wall Street curb. In 1801 the stocks of three banks and three insurance companies and the bonds (then called stock) of the United States were traded in. In 1818 the market had increased to 29 different issues, including the shares of 10 banks and 13 insurance companies. The chief speculation was in the stock of the United States Bank.

After the organization of the New York Stock Exchange in 1817, the stock market developed rapidly with the expansion of the country. It was not many years before it outstripped the Philadelphia exchange, which had been the pattern on which it had been modeled. Bank, canal and industrial stocks long constituted the market, but in 1830 the first railroad stock was listed. Eight years later London also began to trade in American «rails.» In 1835 there were transactions in the shares of five railroads as well as of a number of bank and insurance stocks. The invention of the telegraph added greatly to the scope and power of the stock market. The establishment of the Bank Clearing House in 1853 contributed largely to its security. The creation of a national banking system in 1863, making New York a central reserve city, has by augmenting the deposits of the New York banks, promoted the expansion of the stock market. After the laying of the Atlantic cable in 1866 London prices began to be daily received in Wall Street, the markets of New York and London were brought closer together and arbitrage dealings between the exchanges of the two cities were established. The stock indicators or «tickers»— these being instruments by which quotations are simultaneously recorded in every banker's and broker's office as soon as made in the exchange — were adopted in 1867. Telephones were introduced in 1878.

The Exchange moved from place to place during the first 50 years of its life. It met for several years in the Tontine Coffee House and later in the Merchants Exchange (now the Custom House). Still later its board room was in Lord's Court. It was not until 1865 that it occupied a building of its own in Broad Street. Its earlier methods seem very primitive and crude compared with those of to-day. Its great defect consisted in the lack of a continuous market and in the secrecy with which its business was transacted and its quotations guarded. Still a very active speculation was developed, and during the Civil War the transactions overflowing the regular exchange, were carried on in the streets and were continued in the evening in the corridors of the Fifth Avenue Hotel and in uptown exchanges. The business was indeed larger outside of the exchange than in it. In 1864 a rival exchange was organized, known as the Open Board of Brokers. This was in 1869 consolidated with the older institution, and from this date the history of the Stock Exchange substantially as it now exists, begins. Radical changes were then made in government and methods, the most important being the establishment of a continuous market within specified hours, trading outside of those hours being prohibited. In 1892, the Exchange added to its mechanism a stock clearing house, which by eliminating unnecessary deliveries and reducing the number of certified checks employed in payment for stocks, has diminished the over-certification required by the brokers from the banks, and has thus expanded indefinitely the capacity of the Exchange to transact business. In 1903 the Exchange further increased its capacity by the erection of a new building containing a board room 138 feet long by 112 feet wide and 80 feet high, with every convenience of lighting, heating, and ventilating. So rapid had been the growth of its business in the preceding seven years that the Exchange imperatively needed the larger plant thus provided.

Since its organization in 1817 the Exchange has passed through a series of panics, the most severe having been those of 1837, 1857, 1873, and 1893. In 1873 the panic was so disastrous that the Exchange was compelled to close its doors for 10 days. There were briefer and less severe crises in 1818, 1826, 1848, 1866 and 1884. All these were periods of commercial reaction, the effects of which were felt all over the country, and indeed in all parts of the world. But there have been many periods of excitement in the market that were confined almost entirely to the arenas of the stock exchanges alone. The most notable of these was Black Friday, 24 Sept. 1869, which date marked the collapse of the celebrated gold conspiracy of that year. No other day in Wall Street history has equaled that in its concentrated excitement and passion and its wide contrasts of hopes and despair. The suspension of the Barings in London in 1890 produced a severe convulsion in the stock markets of Europe and America. In December 1895 the London and New York exchanges were convulsed by a sharp fall in prices as a consequence of President Cleveland's Venezuelan message, which contained a clause that seemed to threaten war between the United States and England. The excitement died out and the markets recovered their equilibrium as soon as it appeared that war would be averted. Another notable day in Wall Street was 9 May 1901, when the Northern Pacific corner and panic resulted in a collapse of prices, and the heaviest day's transactions on record, the total sales of stocks having been 3,336,695 shares.

As the New York Stock Exchange is the most important institution of its kind in the United States, and one of the three most important in the world, a description of its mechanism will answer for all the others. Its membership is limited to 1,100. Vacancies occur only by reason of death, resignation, insolvency or expulsion for fraud. A membership or «seat,» as it is called, is a valuable asset, and can be transferred by sale to any one approved by the governing body of the Exchange. The price of seats vary, being high in time of speculative activity and low in periods of stagnation. In 1871 seats were sold at $2,750. In 1885 the price had advanced to $34,000. In the dull year of 1896 it was as low as $13,000. Late in 1901 and early in 1902 it reached the high point of $81,000. In 1903 seats were sold at $60,000. The price of seats is a good index to stock market activity. Besides the price of a seat the applicant for membership must pay an initiation fee of $1,000. He must be a citizen, of legal age and receive 10 affirmative votes out of a committee on admissions composed of 15 members.

The London Stock Exchange has upward of 5,000 members, who are re-elected every year. Applicants for election must be recommended by three members of fours years' standing. Unlike the New York Exchange, the London institution admits to its floor a large number of apprenticed clerks of members, and these clerks may, after four years' service, themselves become members on fulfilling all the requirements governing admission. The Paris Bourse is composed of 60 agents de Change. To secure election, the applicant must be recommended by his predecessor and approved by the authorities of the Bourse and the minister of finance.

The membership of the New York Stock Exchange represents many parts of the United States. Bankers and brokers doing business in Chicago, Philadelphia, Boston, St. Louis, Buffalo, Detroit, and other cities are included in it. Many well-known financiers, as for instance, John D. Rockefeller, George J. Gould, E. H. Harriman and Russell Sage are members. But there are other capitalists equally prominent, as for instance, J. Pierpont Morgan and Jacob H. Schiff, whose names are not on its rolls. Such men as have been named, whether members or not, do business through those members who serve as brokers. Only about one half of the members act directly for outside speculators and outside investors. The others are either capitalists whose memberships enable them to have their orders executed at reduced commissions, or "room traders," who speculate on their own account, or "two dollar brokers," who execute the orders of other brokers, or "specialists," that is, men who are expert in certain inactive securities of which they make a special study.

The Exchange requires of its members the most honorable conduct and imposes severe penalties for fraud. It requires its members to maintain certain established rates of commission. For outsiders the rate is one eighth of 1 per cent, which amounts to $12.50 on 100 shares having an aggregate par value of $10,000. Business is done by members for members, who do not give up the names of principals at 1-32 per cent, and for members naming their principals, at 1-50 of 1 per cent, or $2 per 100 shares. The exchange is open every business day at 9.30 A.M., but no business is allowed until 10 o'clock. The sessions last until 3 P.M., except on Saturday, when the close is at noon. There is a chairman, but his duties are simply to open and close the sessions, make any necessary announcements, such as insolvencies and deaths, and to maintain order by fining members guilty of unruly conduct.

There are no "calls" and no formalities whatever. The members simply meet on the floor and those having stocks to buy or to sell make oral announcement of the fact, together with the amount and the price. Prices are made in fluctuations of eighths of 1 per cent, and no seller can offer stocks down more than one eighth of a point at a time. In the Board Room are a number of posts on which the names of the more active stocks are recorded and transactions in these stocks take place around these posts. All transactions are by word of mouth, the brokers simply recording the sales on little pads and communicating them to their offices by telephone. Nowhere else in the world is a man's oral promise so faithfully fulfilled as in a stock exchange. The sales, as made, are obtained by a corps of official reporters, and are immediately recorded on the "tape" of the stock indicator, of which there are about 1,800 in different offices and hotels throughout the city. The "tape" is a narrow ribbon of paper which feeds itself into the indicators and after receiving the printed impressions giving the sales and prices made in the Exchange, falls into baskets placed under the machine. No stocks or bonds are actually exchanged in the board room. All that takes place there are oral promises to deliver or receive a certain number of securities at a certain price. The actual delivery, if the transaction is "regular," must be made before 2.15 P.M. on the day following the sale. Transactions, however, may be made for delivery the same day, or for 3 days later, and there are buyers or sellers' options for not less than 4 or more than 60 days. No fictitious sales are permitted. Transactions are commonly for 100 shares or multiples thereof. The certificates of stocks must be in approved form for acceptance on delivery. Not later than one hour after the close of the Exchange the seller is obliged to compare or endeavor to compare each sale at the office of the buyer. All active stocks pass through the clearing house of the Exchange.

A stock clearing house was first established in Frankfort in 1867, and was speedily adopted in other European cities, and later in Philadelphia, but it was not until 1892 that it was put into operation in New York. Its success there is shown by the fact that in the great year of speculation of 1901 the number of shares cleared, both sides, including balances, was 926,347,300, having a value of $7,853,500,000. Clearances reduced the actual deliveries to 134,391,000 shares, having a value of $10,930,853,000. The check certifications that were obviated amounted to $17,065,042,800.

All sales made at the Exchange are for actual delivery and for payment in full on delivery. The broker carries stock for his customer on margin, which is usually 10 per cent of the market price, but the broker himself pays for the stock in full. In order to do this he deposits these securities with a bank, trust company or other lender of money as security for a loan. The lender usually requires from the broker a margin of 20 per cent. The process of speculation in brief, thus proceeds as follows: The customer orders his broker to purchase a certain number of shares at a certain price, or at the prevailing market price, at the same time depositing with the broker a sum of money equal to at least 10 per cent of the value of the stock. The broker immediately executes the order on the floor of the exchange. He compares the transaction with the broker who sold him the stock within one hour after the close of the Exchange. The transaction, if in an active stock, then passes through the clearing house. Unless it is eliminated by the clearing, the broker selling has to deliver the stock before 2.15 P.M. the following day, the broker buying giving a certified check, in full payment for the same. He then takes the stock and obtains a loan upon it from a bank. In this way transactions may be extended almost indefinitely, the only limit being the capacity of the banks to extend the necessary credit. The customer who has bought the stock may order it to be sold when the price has advanced, and his profit is the difference between the purchase and the selling price, minus the broker's commission and interest on the credit he has obtained.

If the operator sells for a decline in price the transaction is the reverse of this, although it follows substantially along the same lines. In this case stock is sold which the customer does not own. The broker, however, borrows the shares from another broker in order to make delivery, and when the price declines, if the customer so orders, he buys to cover the shortage, the profit to the customer being the difference between the selling and the buying prices, less commissions and interest. Speculation is mostly in the common stocks, preferred stocks and bonds being, as a rule, of the investment class. Investment, as distinguished from speculation, means the purchase of securities, paying for the same in full, and keeping them in safe deposit vaults for the income they yield.

The speculative transactions vastly outnumber the investment. In 1901 the sales of stocks aggregated 252,723,292 shares, an average of nearly 900,000 shares every day, and the vast bulk of this business was in the common stocks and for speculation upon margins. The total par value of the shares traded in amounted to $25,272,329,200.

The Exchange has strict regulations governing the admission of securities to the privileges of its market, and requires a large degree of publicity in regard to their financial condition from the corporations applying for the privileges of the list. The Exchange, however, has an unlisted department in which stocks and bonds which do not conform to these regulations may be traded in. Such unlisted securities labor, however, under some disadvantages, the banks often discriminating against them in the making of loans. In 1903 there were about 1,300 different stocks and bonds admitted to dealings in the listed and unlisted departments, these having an aggregate value of about $18,000,000,000. Less than 8 per cent belonged to the unlisted class. Securities not admitted to the Stock Exchange are traded in on the curb. The curb market requires the services of over 100 brokers and at times does an active business.

The Stock Exchange has a language of its own, the processes of speculation requiring many terms not commonly used in other lines of business, though some of them are now being generally adopted throughout the country. A «bull» is one who buys in anticipation of higher prices. He is «long» when he has bought or «loaded up» with a «line» of stocks. He sells to «realize» his profits, or is «wiped out» when his «margins» are exhausted. A «bear» is one who sells in anticipation of lower prices. He is «short» when he has thus sold what he does not own. He «covers» when he buys to realize his profits, or to protect himself against further loss in case prices advance instead of decline. He is caught in a «corner» when he finds that he cannot buy in order to make good the stock he has borrowed for delivery, the return of which has been demanded. He is then obliged to settle practically at a price fixed by those to whom he and other shorts have sold. «Lambs» are novices in speculation, and they are well «sheared» when the professional operators have succeded in relieving them of their margins. A «bucket shop» is a bogus brokerage establishment where there is no actual transfer of securities, but where bets are registered on the course of prices. These are a few of the best-known Wall Street terms. There are, however, many others.

The other stock exchanges in the United States are commonly conducted on the same system as that of the New York Stock Exchange. Their business, however, is for the most part in local securities, while the New York Stock Exchange is national in its scope, its market including the securities of the entire country, and a very few of other nations. The methods of the London Exchange are quite different. There the settlements are made every two weeks. In New York they are made every day. In London, there is a system of jobbers and brokers which is unknown on this side of the water. The jobbers are the wholesalers and the brokers the retailers in stocks. The brokers deal with the public, and the jobbers only among themselves and with brokers. The term «stock jobbing» springs from this system. The New York Exchange is governed by a governing committee elected by the members. This committee has almost absolute power like the directors of a corporation. There is a president elected every year. Governors serve four years, but their terms are so arranged that one fourth of their number retire each year. The London Exchange is controlled by a stock company, commonly called the «house,» having £240,000 capital, the shares being held by about one fifth of the members of the exchange. No more than 200 shares can be owned by one member.

Exchanges dealing in grain, cotton and coffee employ a system of which the principles are the same as in the stock exchange though worked out somewhat differently. Actual delivery of all product sold is contemplated in every trade, although the number of deliveries is reduced by clearances involving the settlement of differences. Brokers carry the grain, cotton or coffee for their customers on margin. The products may be bought for immediate or cash delivery or for delivery at some future period. The «option» system, as it is called, involves this principle of purchases for delivery months ahead. For instance, grain may be bought in March for delivery in December. Contracts mature on the last day of the month. If not settled for then, there is a default of contract. The established brokers' commissions for round trades, that is to say, for buying and then selling (thus completing the transaction), are $6.25 per 5,000 bushels of grain; $10 per 100 bales of cotton, and $20 per 250 bags of coffee. The usual margins demanded are, on grain, $250 per 5,000 bushels; on cotton $100 per 100 bales; and on coffee $325 per 250 bags.

The difference of one «point» in the price of stock amounts to $100 per 100 shares. The difference of one eighth of a cent a bushel in the price of grain amounts to $6.25 per 5,000 bushels. A point in cotton is one one-hundredth of a cent and amounts to $5 per 100 bales of 500 pounds each.

Ever since the first stock market was established, numerous attempts have been made to limit its operations and reduce the evils of over-speculation by legislation. The English Parliament passed an act to suppress stock jobbing in 1734. About 10 years ago an effort was made in this country to prohibit option dealings in agricultural products by law, and it has several times been proposed to restrict the operations of the stock exchanges by heavy taxation of all margin transactions. Legislation of this character has, however, failed of passage in the United States. In Germany, however, in 1894, laws were passed which greatly reduced speculation on the Berlin Bourse and for a time closed the Produce Exchange. So injurious was this to the financial and agricultural interests of Germany that the government is strongly in favor of the repeal or amendment of the law, and has in fact largely modified its enforcement. Those interested in this branch of the subject may read with profit an article on the Berlin Bourse which appeared in the 'Century Magazine' of September 1903. A powerful defense of the functions of the stock exchanges against the many criticisms which have been made upon them was given in an article in the 'Atlantic Monthly' early in 1903, written by Charles A. Conant. Books on Wall Street are not numerous, although there are many volumes of statistics, and brokers often issue works of reference and advice in the art of speculation. One of the earliest books which I have seen relating to Wall Street was issued in 1837, and is entitled 'A Week in Wall Street.' It gives an account, although an inadequate one, of the then existing mechanism of the exchange. An excellent 'History of the New York Stock Exchange' by its former president, Francis L. Eames, was printed in 1894 for private circulation, and is now out of print. A comprehensive account of the London Stock Exchange is contained in Charles Duguid's 'The Story of the Stock Exchange' (1901). The general description of the entire mechanism of Wall Street, with a history of its evolution, is given in 'The Work of Wall Street,' by Sereno S. Pratt (1903). Several excellent little volumes have been issued by S. A. Nelson entitled, 'The A B C of Wall Street'; 'The A B C of Stock Speculation'; 'The Theory of Stock Speculation'; etc. The best account of the laws governing speculative transactions is given by John R. Dos Passos' 'Treatise on the Law of Stock Brokers and Stock Exchanges' (1882). George R. Gibson has issued several pamphlets describing the operations of the European exchanges. Those interested in the history of speculation in the United States will find entertaining matter in Henry Clews' 'Twenty-eight Years of Wall Street.'

The exchanges are described by many writers as simply gambling establishments, but speculation has its uses as well as its abuses. One of its advantages is to give mobility to capital, which is thus enabled to turn quickly from one enterprise to another. Thus have the achievements of centuries been crowded into as many decades. There is no doubt that the exchanges, notwithstanding the great evils of over-speculation, have contributed mightily to the rapid development of America.

SERENO S. PRATT,
Associate Editor of the Wall Street Journal.

Exchequer, ěks-chěk'ėr, in Great Britain, the department which deals with the moneys received and paid on behalf of the public services of the country. The public revenues are paid into the Bank of England, or the Bank of Ireland, to account of the exchequer, and these receipts as well as the necessary payments for the public service are under the supervision of an important official called the controller and auditor-general. The public accounts are also audited in his department.

Exchequer Bills, bills of credit issued by authority of the British Parliament as a means of raising money for temporary purposes. They are of various sums — £100 or any multiple of £100 — and bear interest (generally from 1½d. to 2½d. per diem on £100) according to a rate fixed at the beginning of each year. These bills pass from hand to hand as money, and form a principal part of the public unfunded debt of Great Britain. Exchequer bonds are similar, but they run for a definite number of years at a fixed rate of interest.

Exchequer, Chancellor of the. See CHANCELLOR.

Exchequer, Court of. See COURT.

Exchequer Tallies, seasoned wands of asn hazel or willow, formerly used for checking accounts in the English exchequer. Notches cut on the tally indicated by their form the class to which the account belonged.

Excipient (from Lat. *exipere,* take up, undertake), in pharmacy, an inert substance used to give form and consistence to solid preparations, such as pills, or to give palatability and the necessary qualities for administration to any medicine. The various conserves, also honey, treacle, simple syrups, glycerin, white of egg, and mucilage of acacia are among the most useful excipients.

Excise, a government inland duty or impost laid on commodities consumed, or on their retail, which is the last stage before consumption. Many articles, however, are excised at the manufactories. The word seems to be derived from a Dutch term of similar meaning, which in turn may be of same origin as *assise,* its present form being influenced by a supposed derivation from Latin *excisus.* For a more detailed explanation of excise, see CUSTOMS; INTERNAL REVENUE.

Excise Laws, in the United States. The long struggle of the English people against excise was not due to any intrinsic iniquity in the tax, but partly to popular dislike of all direct taxes (see CUSTOMS; TARIFF); partly to the inquisitorial methods involved, partly to their use as a means of strengthening the royal power against popular control. At any rate, the colonists inherited this unreasoned dislike, even under totally different conditions; though Connecticut had laid an excise on spirits and all use of foreign articles, and Massachusetts and Pennsylvania on spirits, before the Revolution. But all shrank from giving the national government such power, and several States proposed amendments to the Constitution forbidding the United States ever to lay excises. Hamilton, however, recommended to Congress in 1790 an excise on spirits, upon the most advanced modern grounds — that it would not only produce a revenue without burdening any worthy industry or person, but would check the consumption, to the great advantage of the community. With great opposition the law was passed, imposing a duty of 9 to 25 cents a gallon (according to strength) on all native spirits, and a higher one on imported. In 1792 the tax was lowered somewhat. Later, under Hamilton's advisement, the scope was extended to other articles of luxury, auction sales, stamp duties on instruments of exchange, etc. But it was nullified in some sections by passive resistance; at last in 1794 a furious open defiance began in Pennsylvania (see WHISKEY INSURRECTION), which had to be quelled by the regular army. There was no further resistance, but no cessation of the dislike, which was naturally a Democratic tenet, from the power it gave the general government; and when Jefferson became President, on his recommendation Congress abolished the entire system, which was possible from the large increase in customs receipts. The War of 1812, however, necessitated a fresh resort to it; and duties were laid on spirits (license tax), and the same articles Hamilton had chosen — sugar, carriages, auctions, and exchanges — with salt added. They were repealed in December 1817, and no further excises were levied till the system of internal revenue taxes (q.v.) was adopted in 1862.

Excito-motor Action, the action of nerves distributed to muscular organs the stimulation of which leads to movement. Thus, irritation of a nerve supplying a muscle will lead to contraction of the muscle by excito-motor action, and irritation of certain nerves distributed to blood vessels will lead to contraction of the vessel by acting on its muscular coat. See NERVOUS SYSTEM.

Exclusion, Bill of, a bill introduced into the British Parliament during the reign of Charles II. for the purpose of excluding the Duke of York, he being a Roman Catholic, from the throne. See CHARLES II.; JAMES II.

Excommunication, an act of ecclesiastical jurisdiction whereby a Christian is separated from the communion of the Church. This power was exercised by the Apostle Paul when in his first letter to the Corinthians, ch. v., he writes concerning a man guilty of incest that he «delivers such a one to Satan.» Authority for excommunication is found in the words of Christ reported in Matt. xviii. «If he will not hear the church let him be to thee as the gentile and the publican.» In the Roman Catholic Church there are two degrees of excommunication — major and minor. By the minor an offender is deprived of the use of the sacraments; by the major one is deprived of all manner of communion or communication with the faithful. In the times when the laws of the Church were enforced in their primitive rigor, the excommunicated were denied communication with the faithful not only in sacred things but in the common life. This is greatly modified now, and persons who have incurred the uttermost ecclesiastical censures suffer only the spiritual penalties attached to their offenses. But though the Church's excommunication has in the present time lost all its civil effects, a brief notice of these effects is necessary for an appreciation of the condition of an *excommunicatus vitandus,* that is, of a person under the major excommunication, who must be avoided by the faithful, under penalty of themselves incurring the minor excommunication.

A person who is under the major excommunication is disqualified for acting as judge or juror, notary, witness in courts of law, advocate, attorney; but he is competent to plead his own cause and to sue others on his own behalf. He cannot be a guardian of a minor, nor curator, nor executor of a last will, nor can he make contracts. He cannot act as a legislator. After death his body is deprived of Christian burial: and if it does get burial in consecrated ground in whatever way, it is to be dug up and cast out. The excommunicate under major excommunication must be shunned by all the faithful: they must not, under pain of excommunication (minor), communicate with him either by word of mouth or by writing; must not greet him, nor have exchange of gifts with him. If an *excommunicatus vitandus* happens to enter a church while the Mass is proceeding, he must forthwith be put out; if that cannot be, then the service must be suspended. Such is the letter of the laws; but long before these stern prescriptions went into desuetude there were notable assuagements of their rigor through the interpretations of moralists. To illustrate this by one example only: The serfs and servants and the children, grandchildren and other relatives (even by affinity only) were permitted to continue their relations of obedience and respect to their head even after he was excommunicated.

Excretory System, Comparative Anatomy of the. See ANATOMY.

Execu'tion, in law, the carrying into effect the final judgment, decree, or order of the court. Execution is effected by a writ or order directed to the proper officer and commanding him to do a certain thing. In civil law it is the means of obtaining that which the court ordered to be done by one of the parties. Execution may be had for either plaintiff or defendant. When taken out by the plaintiff it depends on the cause of action as to what is to be recovered under the writ; generally it is for the debt and costs, or for the goods, damages, and costs. When taken out by the defendant it may be for goods, damages, and costs, and in some cases it may be only for costs.

As soon as final judgment has been entered, the party entitled to it may take out his writ of execution, and he is entitled to this writ until the other party has taken some step which is a *supersedeas,* such as an appeal or writ of error. The writ issues from the court which last passed on the judgment on which the writ of execution is taken out. Execution may be against personal property, taking and selling it, or it may be against real estate, either holding it until the judgment is paid, or selling it, or in some cases by the seizure of the person of the defendant and holding him until the judgment is satisfied, or until he is declared insolvent. If the property is sold the fund derived from the sale is applied to paying the judgment and costs, and the surplus, if any, is returned to the former owner of the goods. A writ of execution, although issued at the instance of the party in whose favor the judgment is, must be directed to the sheriff, who must carry out the direction of the writ. If he fails to do so he must answer in damages to the injured party. When the execution is against personal property, such as goods and chattels, the writ of *fieri facias* is used. When the personal property consists of choses in action it is reached by a writ of attachment. If the execution is against real estate a writ of *scire facias* is used, and it is sold under a writ of *venditioni exponas*. In some cases, when the judgment is confined to a particular piece of real estate, the writ of *levari facias* is issued first, and it is sold under a writ of *venditioni exponas*. If the execution is against the person of the defendant a writ of *capias ad satisfaciendum* is issued, under which the defendant is arrested and his person held until the judgment is satisfied, or until the defendant is declared insolvent. Sometimes the defendant is released if security is given that the defendant will abide by the order of the court.

A general judgment binds all property owned by the person against whom the judgment is recovered at the time the judgment is entered, and it also attaches to all property he acquires up to the time the judgment is satisfied, and if the debtor sells any real estate before the judgment is satisfied, the property is not released from the lien of the judgment. When property is sold under an execution the purchaser only buys the title of the debtor, and all equities under which he held it still attach to the property.

In the criminal law execution is the carrying into effect the judgment of the court in relation to the person convicted. It consists in putting the convict to death according to his sentence. See CAPITAL PUNISHMENT.

Execu'tioner, the official who carries into effect a sentence of death, or inflicts capital punishment in pursuance of a legal warrant. In England it is the province of the sheriff to execute the extreme sentence of the law, but in practice the disagreeable duty is performed in his presence by an officer retained for this purpose. In Scotland the duty devolves upon the civic magistracy, but the strict letter of the law is avoided as in England by the attendance of a magistrate to witness the proceedings. Several executioners have become famous from their names being dragged into literature; such as Richard Brandon, the supposed headsman of Charles I.; Jack Ketch, commemorated by Dryden (Epilogue to the Duke of Guise), whose name was long vulgarly given to all who succeeded him (in London) in this odious office. In America, the title and duties of the public executioner differ in the various States. In some States the sheriff of the county becomes the executioner, but in New York State the warden of the penitentiary is technically the executioner. The duties are usually performed by one of his subordinates. In the army the provost-marshal is the military executioner. See CAPITAL PUNISHMENT; ELECTROCUTION; GUILLOTINE; HANGING.

Exec'utive, in the United States, roperly the entire official body charged with the execution of the laws, from the head to the lowest subordinate; but in current use, restricted to the head officer, as President (of the United States), governor (of a State), mayor (of a city), etc. (See CABINET.) The general executive of the colonies was the king; their individual executives, the governors, appointed by the crown or (in Rhode Island and Connecticut, and for a few years in Massachusetts) chosen by the people. These were succeeded *de facto* by the committees or councils of safety; then by officials usually called governor, sometimes president, and sometimes not by single persons, but by executive councils as in Switzerland. The general government had no executive till the adoption of the Constitution. The Continental Congress had only such functions as the State legislatures allowed it, which were to debate and ask for supplies and make recommendations, and the Articles of Confederation provided for no executive. The Constitution, although it gives the President large executive powers, compels him to share the most important, as appointments and treaties, with the Senate; it was only after debate, indeed, that a single executive was resolved on, there being a strong sentiment in favor of a plural executive representing different sections of the Union, and three States voted in favor of the latter in committee of the whole. (For the steady encroachments of Congress upon the President's executive powers, see CONGRESS.) The question of succession of executive power in case of the death or disablement of the chosen executive has been elaborately provided for by statute; in case of the President, first by succession of the Vice-President, then by a series of devolutions upon the various officers of the Cabinet, beginning with the secretary of state — so that nothing but a successful Gunpowder Plot, or rather a number of simultaneous ones, could paralyze national executive authority. The embarrassing cases of possible lunacy, paralysis, etc., have never arisen, nor has capture by the enemy; though the latter has twice been imminent — of Madison by the British in 1814, of Lincoln by Booth (the original plan) in 1865. But cases which have not occurred in 114 years may be left to deal with when they do occur. (For the problems of presidential elections, see ELECTORS; ELECTORAL COMMISSION.) The executive departments were first created in 1781 — Foreign Affairs, Finance, War, and Marine; previously, their work had been done by Congressional committees, or commissions appointed by them. They were reorganized in 1790.

Exec'utor (Lat. "performer"). An executor is one to whom another man commits his last will and testament for execution of that last will and testament (2 Black. Comm. 503). A person to whom a testator by his will commits the *execution*, or putting in force, of that instrument and its codicils. The following is a brief summary of an executor's duties:

(1) He must bury the deceased in a manner suitable to the estate left behind. But no unreasonable expenses will be allowed, nor any unnecessary expenses if there is risk of the estate's proving insolvent. (2) Within a convenient time after the testator's death, he should collect the goods of the deceased, if he can do so peaceably; if resisted he must apply to the courts for relief. (3) He must prove the will, and take out administration papers. (4) Ordinarily, he must make an inventory of personal property, and, in some States of real estate also. (5) He must next collect the goods, and chattels, and the claims inventoried, with reasonable diligence. And he is liable for a loss by the insolvency of a debtor, if it results from his gross delay. (6) He

must give notice of his appointment in the statutory form, and should advertise for debts and credits. (7) The personal effects he must deal with as the will directs, and the surplus must be turned into money and divided as if there was no will. An administrator must at once collect, appraise and sell the whole. The safest method of sale is a public auction. (8) He must keep the money of the estate safely, but not mixed with his own, or he may be charged interest on it. (9) He must be at all times ready to actually file an account within the year generally prescribed by statute. (10) He must pay the debts and legacies in the order required by law. Funeral expenses are preferred debts. See ESTATE.

Exegesis, Biblical. The world "exegesis" is from the Greek ἐξήγησις, primarily *a leading out,* and coming to mean, *an interpretation, an explanation, a making clear.* The verb ἐξηγέομαι occurs six times in the New Testament, always in the sense of revealing a fact or making clear a truth, Luke xxiv. 35; John i. 18; Acts x. 8; Acts xv. 12, 14; Acts xxi. 19. In John i. 18, we read, "No man hath seen God at any time; the only-begotten Son, who is in the bosom of the Father, that one became his exegete" (ἐκεῖνος ἐξηγήσατο). That is to say, Jesus *revealed* the inmost character of God. He *made manifest* what otherwise would have remained hidden. He *interpreted* God's being. He *made clear* the Divine providence and plan. His person and his whole teaching and life were an exegesis of the invisible and previously incomprehensible Godhead. What Jesus did for God's being and providence, the exegete endeavors to do for the Bible. He searches for its inmost meaning, explains what is obscure, leads out to the light what is less manifest, makes clear all its implications, and sets its complete import before the mind's eye. The task of Biblical exegesis, therefore, is to clear up all difficulties and to make plain the meaning of the Bible text. It might seem a comparatively easy thing to do this; but centuries of endeavor have shown that while all the essentials of the revelation in the Bible are reasonably clear there are problems connected with all of the Bible books which tax the utmost powers of the greatest minds to master them. Then at least four temptations beset the interpreters of Bible truth. One of these is apparent in those exegetes who

> "Each dark passage shun
> And hold their farthing candle to the sun."

What is clear in itself needs no further explanation. The office of the exegete becomes a necessity only when the meaning seems obscure. Another danger in exegesis is that of bringing a meaning *to* the text instead of drawing the meaning *from* it. The text is forced into agreement with previous prejudice or opinion. This is nearly always fatal to the truth. As an old monk said, "Whosoever seeketh an interpretation in this book shall get an answer from God; whosoever bringeth an interpretation to this book shall get an answer from the devil." Jerome put the same truth more mildly when he said, "He is the best teacher who does not bring his doctrine into the Scripture but out of the Scripture." Sometimes the obvious meaning of the text is unpalatable to the exegete, for doctrinal or other reasons, and then he is tempted to explain the meaning away. This is rankest treason to his calling. He is expected to be loyal to the truth and nothing but the truth. If he betray the truth in behalf of a political party or a church organization or a doctrinal system he is no longer worthy of his office or name. A fourth temptation is that of adding to that which is written, improving upon the text by the addition of unwarrantable inferences and subjective fancies and unjustifiable subtleties of every sort. It represents the presumption of the apostle Peter at Cæsarea Philippi, who thought he knew better than his Lord what ought to be said and done. These are four fundamental faults of all exegesis; a failure to explain the meaning that is obscure, a distorting of the meaning that seems obvious, an utter perversion of the plain truth, and a supplanting of the truth with merely human verbiage or wisdom. Wilful miscarriage, maiming, murder, and the substitution of a changeling for the true child are crimes in the realm of interpretation, as well as under the civil law. The science of exegesis has sought from the first to free itself from these faults. If it has not wholly succeeded as yet, that is simply to acknowledge that like all other science its development has been entrusted to fallible men. We may trace various schools of exegesis through the history of the Church, and in all of them some one or other of these fundamental faults is likely to be manifest.

The first important school of exegesis was founded at Alexandria, and it flourished from 150 to 400 A.D. Its most distinguished representatives were Clement, Origen, Athanasius, Basil, and the two Gregories. Of these the peerless prince was Origen, the greatest scholar and saint the Christian Church has produced since apostolic times. A great injustice has been done both him and the Alexandrian school by associating their names almost exclusively with the allegorical interpretation of the Scriptures, in which they sometimes indulged, as though this method were their only method or were peculiar to them alone. Neither of these things was true. The allegorical interpretation was much older than the Alexandrian school and has persisted in dragging out its pernicious existence to this day. It was prevalent and predominant in the Rabbinical schools of exegesis before the Christian era began. The Talmudists finally found a watch-word for their mystical exegesis in Pardes, or Paradise. The four letters of this word in the Hebrew, P R D S, were made to indicate the four words, Peshat or explanation, Remes or hint, Darush or homily, and Sod or mystery; and these in turn represented the four-fold interpretation of which every passage in Scripture was capable. Rabbi Ishmael declared that by means of these any Scripture could be expounded in forty-nine ways and the expositor could break every text into fragments, even as a rock is broken by a hammer (Sanhedrin, 34). The apostle Paul carried at least one example of allegorical treatment into our New Testament, probably suggested by his Jewish training in the school of Gamaliel, Gal. iv. 22-31. This method was introduced into Alexandria by Aristobulus and pseudo-Aristeas, and it became authoritative as a method of exegesis under Philo, the foremost writer among the Alexandrian Jews contemporary with the Christ. Philo found the method ready made to his hand, not only by the Jewish rabbis, but also by the Greek philosophers who had allegorized Homer and Hesiod and the ancient Greek myths into conformity with their more advanced ethics and faith. The Alexandrian church fathers thus found the allegorical interpretation in vogue among their heathen and Jewish neighbors and forbears. They believed it had a Scriptural sanction. They accepted it without question. Their genius and wide influence gave it a standing in the Christian Church for centuries; but the Alexandrian school never had a monopoly of its use. It is unfair, therefore, to hold them responsible, either for the origination or for the promulgation of this method of Scriptural interpretation. Origen did teach that there was a three-fold sense in Scripture, corresponding to the body, soul, and spirit in man—a literal and a moral and a mystical sense. But Jerome also made it a rule that the Scripture should be interpreted in three ways, historically, tropologically, and spiritually; and he related this three-fold division to the doctrine of the Trinity. And Augustine formulated one principle of his exegesis in these words, "Whatever there is in the word of God that cannot, when taken literally, be referred either to purity of life or soundness of doctrine, you may set down as figurative" ('De Doctr. Christ.' III. ch. 10. sect. 14). He wrote to Honoratus, "All that Scripture, therefore, which is called the Old Testament, is handed down four-fold to them who desire to know it, according to history, according to ætiology, according to analogy, according to allegory" ('De util. credendi,' 5). This four-fold division was adopted by many of the church fathers and found its final formulation in the famous couplet of Nicholas of Lyra,

Littera gesta docet, quid credas Allegoria,
Moralis quid agas, quo tendas Anagogia.

A good example of this four-fold sense was the Scriptural use of the word, Jerusalem. Literally, it was a city; allegorically, the church; morally, the individual believer; anagogically, the heavenly state.

This much may be said for the Alexandrian school in connection with the allegorical interpretation of the Scripture. (1) It did not originate this method. (2) It never exercised any monopoly in its use. (3) It found what seemed to it a sufficient sanction in the typology and allegory of the Apocalypse, the Pauline epistles, and the epistle to the Hebrews. (4) No other method of interpretation would have availed them, in their stage of Biblical knowledge and in their environment, for the defense of many portions of the Old Testament. Their adequate apology for yielding to the fourth temptation mentioned above is to be found in the necessities of their case. (5) Their use of this method grew out of their very piety and spirituality. These simply joined forces with their poetical imagination and philosophical insight in the endeavor to save the Scripture from contemporary disrepute. (6) They never used the allegorical method dogmatically and they avoided most of the excesses of the later day. "They are always intelligent and reasonable. They evaporated the letter; they did not stereotype the spirit" (Bigg, 'Christian Platonists of Alexandria,' pp. 149-50). Making all allowance for fault at this point, the fact remains that "Origen was the greatest Biblical critic and exegete of the ancient church" (Terry, 'Biblical Hermeneutics,' p. 639). His one object was to find and to set forth the edifying truth in the Scripture. He said, "The passages that are true in their historical meaning are much more numerous than those which are interspersed with a purely spiritual signification." Having adduced many passages in which a literal meaning seems impossible, he concludes, "Therefore, the exact reader must, in obedience to the Saviour's injunction to search the Scriptures, carefully ascertain in how far the literal meaning is true, and in how far impossible; and so far as he can, trace out, by means of similar statements, the meaning everywhere scattered through Scripture of that which cannot be understood in a literal signification" ('De Principiis,' IV. 1; 19). This is seen at once to be, as Davidson said, "not so absurd or injurious as many represent" ('Sacred Hermeneutics,' p. 68). Bishop Lightfoot is fully justified in saying of Origen, "A very considerable part of what is valuable in subsequent commentaries, whether ancient or modern, is due to him. A deep thinker, an accurate grammarian, a most laborious worker, and a most earnest Christian, he not only laid the foundation, but to a very great extent built up the fabric of Biblical interpretation" ('Commentary on Galatians,' p. 227). Farrar declares, "His knowledge of the Bible and his contributions to its interpretation were absolutely unrivalled" ('History of Interpretation,' p. 188). Fairweather adds, "Properly speaking, Origen was the first exegete. Everything done in this direction previously had been merely preparatory to a scientific interpretation of Scripture . . . One of the great merits of Origen is that he never shirks a difficulty. . . . Nothing could exceed his passion for verbal and grammatical accuracy, or his linguistic and critical insight, while his knowledge of the ancient theology is unique" ('Origen,' p. 120). Harnack calls Origen "the father of ecclesiastical science in the widest sense of the word," and says that he "was an exegete who believed in the Holy Scriptures and indeed, at bottom, he viewed all theology as a methodical exegesis of Holy Writ" ('History of Dogma,' II. pp. 332, 335). In Origen, therefore, we find the founder of scientific exegesis and the great master in this field. His faults were those of his age; his excellences have been an abiding blessing to the Church. Our age is coming to agree with Gregory Thaumaturgus in his Panegyric, when he says of Origen as an exegete, "That greatest gift that man has received from God, and that noblest of all endowments, he has had bestowed upon him from heaven, that he should be an interpreter of the oracles of God to men, and that he might understand the words of God, even as if God spake them to him, and that he might recount them to men in such wise as that they may hear them with intelligence. . . . He explained whatsoever was dark or enigmatical, . . . and set it in the light, as being himself a skilled and most discerning hearer of God. . . . He alone of all men with whom I have myself been acquainted, or of whom I have heard by the report of others, has so deeply studied the oracles of God, as to be able at once to receive their meaning into his own mind, and to convey it to others. For that leader of all men, who inspires God's dear prophets, and suggests all their prophecies and their mystic and heavenly words, has honored this man as He would a friend, and has constituted him an expositor of these same oracles; the things of which He only gave a hint by others, He made matters of full instruction by this man's instrumentality; and in things which He, who is worthy of all trust, either enjoined in regal fashion, or simply enunciated, He imparted to this man the gift of investigating and unfolding and explaining them; so that, if there chanced to be any one of obtuse and incredulous mind, or one again thirsting for instruction, he might learn from this man, and in some manner be constrained to understand" (Argument, XV.) It is the picture of the perfect pattern of the union of scientific investigation and spiritual insight which makes the model exegete. The transcendent genius of Origen lifted him above his age at many points, and the twentieth century is beginning to see that his conception of revealed truth is far superior to that of most of his successors in the history of the church.
